PRESUMED HYBRID BETWEEN CINCHONA CALISAYA AND C. SUCCIRUBRA.

BY JOHN ELIOT HOWARD, F.R.S., ETC.

In the Pharmaceutical Journal of July 12th of last year, and subsequently in a communication to the Linnean Society, "On the Genus Cinchona,"* I gave some account of the produce obtained from seed sent me by Mr. Broughton, "from two trees of the same red-under-leaved variety of Calisaya." In the latter treatise I have discussed the question as to the probability of the variable aspect of the plants having been the result of hybridization or otherwise. I have since obtained some fresh light on the subject, which it may be well to place on record.

Towards the close of the third week in May of this year, when the plants were just two years old, I cut down five of them, leaving some inches of the stem to sprout again. From the remainder I peeled the bark, which weighed, when fully dried, 880 grains. One of the stems I forward, to show the size and growth of the plants. On subjecting the bark to chemical examination, I found to my surprise, that I had to do with a substance partaking, in something like equal proportions, of the qualities of red bark and of Calisaya bark. I obtained a crystallization of mixed sulphate of quinine and sulphate of cinchonine, the latter existing in true Calisaya in very minute proportion, if at all. By recrystallization (with precautions), the sulphate of quinine was brought into a state of pure and white crystals, justifying the Calisaya character of the parent trees from which the seed was obtained. On the other hand the residuary alkaloid was, as usual from the *C. succirubra*, largely impure or uncrystallizable.

Certain peculiarities in the products, led me to search for quinamine, and after precipitation† of the residuary alkaloids by potassic sulphocyanide, I obtained, by precipitation and resolution in pure ether, a substance which certainly had a close resemblance to the quinamine of Hesse, crystallizing by spontaneous evaporation in long needles, forming a peculiar tracery on the sides of the glass vessel.

In my description of the bark of *Cinchona succirubra*, I have said,‡ that "the characteristic peculiarity of red bark is, that it ordinarily contains the alkaloids quinine, cinchonine, cinchonidine, quinicine (?) and aricine (?)." This result of my researches was published in 1862, and some ten years before *Quinamine* had been determined. I have no hesitation in saying that the recent examination of the bark of my five trees has given me again the same results; thus still more strongly indicating the effect of hybridism, than even by the large amount of cinchonine contained.

As nearly as I could ascertain, the bark of these five trees produced:—

Sulph. quinine	0·170
Sulph. cinchonine	0·170
Cinchonine	0·170
Quinamine (?)	0·100
Amorphous alkaloids	0·700

The plants themselves partake of the same intermediate character, as I have been able more fully to ascertain since I have had the pleasure of showing them to Mr. Broughton, who is now in England, and has kindly presented me with a collection of eighteen specimens of Calisaya from the plantation of Nediwuttum. Amongst these considerably diverging varieties is a pressed specimen of the No. V. sort, from which all of mine spring. Some of mine resemble this parent, others have so much more the character of *C. succirubra* as to be taken at first sight by Mr. B. for that variety; but whilst in form * and general appearance they resemble the *C. succirubra*, they are distinguished by the peculiar gloss or *reflet* which marks the Calisaya, and which is entirely absent from the *C. succirubra*.

On the whole I think that we may safely conclude that there has been an interference in this case of the pollen of the *C. succirubra*, growing as Mr. Broughton informs me in the immediate neighbourhood. I am the more confirmed in this view, since it accords with observations made by Dr. de Vrij on a hybrid sort in Java. But if such be the case, we are led to curious reflections in connection with vegetable physiology. Through the mixture of the two *essentiæ*, brought about by pollen so nearly similar, a change must have been wrought in the chemistry of each cell of the inner bark; if (as I suppose) it is in these, that the alkaloids are elaborated. I would bring into relationship with this fact the following observations of the skilful chemist attached to the Dutch Plantations of cinchona. M. Moens gives me the following information† (under date 5th. Dec., 1873):—"Some years ago, M. v. Gorkom had grafted two Calisayas upon two Pahudianas. The grafts succeeded very well, and I have recently taken the barks for examination. This showed that the Calisayas as well as the Pahudianas kept their alkaloids as if they had grown

‡ Illus. Nueva Quin. sub voce C. succirubrum, p. 13.

* I have some regularly ovate leaves, measuring fifteen by ten and a half inches.

† My correspondent will pardon some rectifications in expression, needed to convey his meaning clearly.

separately. The latter contained no quinine, or cinchonidine, but quinidine (Pasteur) and amorphous alkaloids. The former gave quinine, cinchonidine (much), no quinidine, chichonine, and amorphous alkaloids. I think this is an experiment of considerable interest, and shall repeat it, if possible, with *C. micrantha* and *C. Calisaya* (Ledger). I think the result most agrees with your idea, that the alkaloids are formed in the cellular tissue of the bark."

For the rest, it would seem that, in Cinchonæ at least, the effect of hybridism tends only to degeneration.

Through the courtesy of my friends in Java, I have just received the Report of the Plantations there for the first quarter of the present year. From this I learn that nine specimens of *C. Ledgeriana* have given equal to 10·03 to 14·82 sulph. quinine, whilst four trees, which (if I understand aright) are reckoned under Ledgerianas, give either no quinine at all, or this alkaloid in comparatively small quantity; and quinidine and (in one case) amorphous alkaloid, in suspicious amounts. Are not these trees also hybrids? These careful cultivators take great precautions to propagate only the true *C. Ledgeriana*, and I hope will be successful in guarding against the injury resulting from the pollen of inferior species.

LIQUOR FERRI PHOSPHATIS CUM QUINIÂ ET STRYCHNIÂ.

In a recent note on Syrupus Ferri Phosphatis, by Mr. Blackett (before, p. 890) he recommended the keeping of a solution of ferrous phosphate with the alkaloid in it for the preparation of a syrup of phosphate of iron, quinine and strychnine, as it may be required. He now writes respecting this suggestion:—

"I have since found that this method does not apply to the 'phosphate of iron, quinine, and strychnine liquor.' The strychnine does not exert any decomposing action, but the quinine does most rapidly cause a decided change of colour. I find that it is very easy to keep a solution of phosphate of iron and strychnine ready, and then add one grain of phosphate of quinine for each drachm of syrup required. Any one can try my suggestions, and calculate out the quantities that may be convenient."

THE APPENDICES OF THE BRITISH PHARMACOPŒIA.

BY WALTER G. SMITH, M.D., DUBLIN,

Fellow and Censor K. and Q. C. P. I.; Examiner in Materia Medica, Q. U. I.; Assistant Physician to the Adelaide Hospital.

(Continued from vol. iv. p. 996.)

APPENDIX II.

SOLUTION OF ACETATE OF COPPER. $Cu\ 2\ C_2H_3O_2 \cdot H_2O$.—Test for butyric acid in Zinci Valerianas: butyric acid precipitates the acetate of copper immediately.

SOLUTION OF ACETATE OF POTASH. $KC_2H_3O_2$.—Test for Acidum Tartaricum: distinguishes it from Acidum Citricum.

SOLUTION OF ACETATE OF SODA. $NaC_2H_3O_2.\ 3\,H_2O$.—Testing Calcis Phosph. Præcip. for iron; to neutralize the excess of the nitric acid employed.

SOLUTION OF ALBUMEN.—Test for metaphosphoric acid (HPO_3) in Acidum Phosph. Dil.; test for Acidum Carbolicum and for Creasotum.

SOLUTION OF AMMONIO-NITRATE OF SILVER. $AgNO_3.\ 2\,NH_3$.—Test for Acidum Arseniosum, and Acidum Phosphoricum; yellow precipitate with each.

SOLUTION OF AMMONIO-SULPHATE OF COPPER. $CuSO_4.\ 4\,NH_3$.—Test for sulphide of ammonium in Liq. Ammoniæ Fortior; gives black precipitate.

SOLUTION OF AMMONIO-SULPHATE OF MAGNESIA.—Test for phosphoric acid in Ammoniæ Phosphas and Ferri Phosphas; gives white precipitate of triple phosphate, $MgNH_4PO_4$.

SOLUTION OF BORACIC ACID.—To detect the adulteration of rhubarb with turmeric. Alkalies could not be used for this purpose, as they act on rhubarb similarly to turmeric.

SOLUTION OF BROMINE. Br.—Test for iodine in bromides of ammonium and potassium.

SOLUTION OF CARBONATE OF AMMONIA. $N_4H_{16}C_3O_8$.—Test for Bismuthum Purificatum; Zinci Carb., Zinci Oxidum.

SOLUTION OF CHLORIDE OF AMMONIUM. NH_4Cl.—In testing for magnesian salts to prevent the premature precipitation of magnesia by ammonia. Triple phosphate is insoluble in chloride of ammonium.

SOLUTION OF CHLORIDE OF BARIUM.—Test for sulphuric acid or a soluble sulphate.

SOLUTION OF CHLORIDE OF CALCIUM. $CaCl_2$.—Test for citric acid in Potassæ Citras; for arsenic acid in Sodæ Arsenias.

SOLUTION (SATURATED) OF CHLORIDE OF CALCIUM.—Test for percentage of nitrous ether in Spiritus Ætheris Nitrosi.

SOLUTION OF CHLORIDE OF GOLD. $AuCl_3$.—Test for atropia.

SOLUTION OF CHLORIDE OF TIN. $SnCl_2$.—Test for Hydrargyrum Ammoniatum.

NOTE.—Stannic chloride, $SnCl_4$, could not be formed in the presence of nascent hydrogen.

SOLUTION OF GELATIN.—Test for Acidum Tannicum; Ulmi Cortex.

NOTE.—Should be termed solution of isinglass, which is introduced into App. I. for this purpose.

SOLUTION OF IODATE OF POTASH. KIO_3.—Should be expunged from the Appendix as it is no longer recognized as a test. In the first edition of the Pharmacopœia it was used as a test for sulphurous acid in Acidum Aceticum.

SOLUTION OF IODIDE OF POTASSIUM. KI.—Test for lead. (See lead salts *passim.*)

SOLUTION OF OXALATE OF AMMONIA. $(NH_4)_2C_2O_4$.—Test for lime. (See calcium salts *passim.*)

SOLUTION OF PERCHLORIDE OF PLATINUM. $PtCl_4$.—Test for potash (see potassium salts *passim*); for nicotia in Tabaci Folia.

SOLUTION OF PHOSPHATE OF SODA. Na_2HPO_4.—Test for magnesia. (See magnesium salts *passim.*)

SOLUTION OF RED PRUSSIATE OF POTASH. $K_6Fe_2Cy_{12}$.—Test for *ferrous* salts. (See salts of iron *passim*).

SOLUTION OF SULPHATE OF INDIGO (Sulphindigotic Acid). $HC_8H_4NSO_4$.—Test for Liq. Chlori; and for nitric acid in Bismuthi Carbonas.

SOLUTION OF SULPHATE OF IRON. $FeSO_4$.—Test for Acidum Hydrocyanicum; and for nitric acid in Acidum Phosphoricum, Liq. Ferri Pernitratis; and for nitrous acid in Spiritus Ætheris Nitrosi.

SOLUTION OF SULPHATE OF LIME. $CaSO_4$.—Test for oxalic acid in Acidum Tartaricum.

SOLUTION OF SULPHIDE OF AMMONIUM. $(NH_4)_2S$. Preparation: see sulphuretted hydrogen, App. I. Test for copper or lead in Liq. Ammon. Fort., and Pot. Acet.; test for zinc (see zinc salts *passim*); and for cadmium (see Cadmii Iodidum).

NOTE.—Sulphydrate of ammonium, NH_4HS, is also frequently used in the laboratory.

SOLUTION OF TARTARIC ACID. $H_2C_4H_4O_6$.—Test for potassium (See Pot. Acet.) and, generally, to distinguish potassium from sodium salts: to prevent precipitation of oxide of iron in testing Ferri Phosph. for phosphoric acid.

SOLUTION OF YELLOW PRUSSIATE OF POTASH. K_4FeCy_6.—Test for *ferric* salts (see salts of iron *passim*); and for copper salts (see Cupri Sulphas).

APPENDIX III.

This Appendix, as has already been remarked, deals with quantitative analysis, which is effected upon one or other of two principles.

1. Analysis by weight—gravimetric, *i.e.*, the precipitation of a body in the free state or in some definite combination, which is then weighed, and so the quantity of the body ascertained by a simple calculation. The requisite operations for this mode of procedure are troublesome, and involve much expenditure of time, and it is unnecessary in this place to allude to them further. But many chemical assays are now more simply effected by—

2. Analysis by measure, *i.e.*, volumetric—with which alone we are now concerned. Briefly, this method consists in noting the volume or bulk of a test-liquid of known strength required to be added to a substance before a given chemical effect is produced upon a known quantity of the substance under examination. Or, as it may otherwise be expressed, it estimates the quantity of a body by converting it from a certain definite state to another equally definite state by means of a fluid of accurately known power of action, and under circumstances which permit of the rigorous determination of the exact point when the conversion is accomplished. For example, the amount of iron in a given amount of a ferrous solution can be easily determined by observing how much of a known solution of the purple potassic permanganate will be decolorized by the ferrous solution. The advantages which the volumetric method offers are rapidity, accuracy, and simplicity of manipulation. An analysis can often be completed in as many minutes volumetrically as it would take hours gravimetrically.

The basis upon which the practical application of this method rests is fourfold.

(*a*) The fundamental decomposition, or initial reaction, of the analysis in question must be fixed and invariable, else no certain results can be attained. Not a few proposed processes have broken down under this requirement.

(*b*) It is necessary to have standard (volumetric or titrated) test solutions, *i.e.*, simply solutions of accurately known strength. These solutions are prepared either (1) by dissolving a weighed quantity of the reagent in a definite volume of water, *e.g.*, all the official solutions, except the volumetric solution of soda, and hyposulphite of soda; or, (2) by first preparing a suitably concentrated solution, determining its exact strength by a series of experiments, and then diluting it to the proper volume, *e.g.*, the volumetric solution of soda.

(*c*) A graduated delivery tube, or burette, for measuring the volume of the test liquid required in a particular operation. Of the different kinds, Mohr's clamp burette is very convenient, and is now in general use. The burette is usually constructed to hold 1000 grain-measures of the solution up to the zero mark. A grain-measure is the volume of a grain of distilled water.

(*d*) We must know the final reaction, or indicator, *i.e.*, the evidence of the completion of the intended decomposition. This always consists in some *visible* change, and is manifested (i.) as a change of colour, *e.g.*, action of acids and alkalies on litmus; (ii.) by the cessation of the formation of a precipitate, *e.g.*, estimation of bromide of potassium and arseniate of sodium by nitrate of silver; (iii.) by incipient precipitation, *e.g.*, estimation of hydrocyanic acid by nitrate of silver; and (iv.) by the use of particular reagents, *e.g.*, in the estimation of ferrous salts by bichromate of potassium red prussiate of potash is employed as the indicator.

The different volumetric methods are conveniently grouped under three heads:—

I. Analysis by saturation or neutralization, *i.e.*, in which the quantity of a base (alkalimetry) or an acid (acidimetry) is measured by the quantity of acid or base which is necessary to convert it into a neutral salt. The indicator used in this case is litmus, and the general method of procedure is as follows:—Weigh or measure the necessary quantity of the substance, dilute, add a sufficient amount of litmus, and run in the acid (or alkaline) test-solution from the burette until a permanent red (or blue) tinge begins to appear.

II. Analysis by oxidation or reduction, *i.e.*, a substance which will take up oxygen is brought into solution and estimated with a substance of known oxidizing power, or *vice versâ*. In other words, the quantity of the substance to be determined is found by the quantity of chlorine, iodine, or oxygen to which it is equivalent as an oxidant, or which it requires to pass from a lower to a higher stage of oxidation, *e.g.*, action of iodine on sulphurous and arsenious acids.

III. Analysis by precipitation, the principle of which is either:—

(*a*) Add the test-solution until no further precipitate occurs, *e.g.*, estimation of bromide of potassium by nitrate of silver, or,

(*b*) Add the test-solution until a permanent precipitate begins to form, *e.g.*, estimation of hydrocyanic acid by nitrate of silver.

The following general statement will explain the simple calculation required in any given case:—

If $n =$ the number of grain-measures of the test solution used in a particular experiment, and $a =$ the weight of the substance tested which corresponds to 1000 grain-measures of the standard solution—always a known quantity—then, by simple proportion,

$$1000 : n :: a : x \text{ (the quantity sought).}$$

With this introduction the special uses of the different official solutions will now be briefly explained, and an illustrative example of each process worked out.

(*To be continued*).

SOLUBLE STARCH.*

BY M. MUSCULUS.

Chemists are not in accord as to what is to be understood by "soluble starch." Some consider as such the matter coloured blue by iodine, which can be removed from starch by means of water, and which Vaegeli has called "granulose." Others think that the substance coloured violet by iodine, which Béchamp obtained by treating

* Abstract of paper read before the French Academy (*Comptes Rendus*, vol. lxxviii., p. 1413).

starch with sulphuric acid, to be the true soluble starch. But the author has found that granulose, although it passes readily through a filter, is not really soluble in water, for it can be separated by evaporation in a state completely insoluble even in boiling water. Also that the soluble starch of Béchamp is a mixture in which may be found granulose, soluble starch, and the products of decomposition of starch (dextrine, glucose, or glucosine), which are always formed with sulphuric acid.

The author has previously made known under the name of "*dextrine globulisée*,"* a body insoluble in cold water, which he obtained by dissolving starch in boiling acidulated water, and evaporating after saturation of the acid and filtration, to the consistence of a syrup. This deposits an abundance of granules, insoluble in cold water and soluble only at 50°C., a property that allows of their being washed and separated from the dextrine and glucose by which they are accompanied; further treatment with alcohol will remove a little granulose still adhering, and there will then be left what the author considers to be true soluble starch; the granules composing it being grains of starch deprived of their organization.

The author enumerates the following properties of this product to substantiate his assertion. When dried in the air it is white and resembles starch. Freshly washed, it is insoluble in cold water and does not reduce salts of copper; but if it be left for some time in contact with water, it dissolves perceptibly and there is at the same time a little sugar formed. Its rotatory power is nearly quadruple that of dehydrated glucose. It dissolves entirely in water at 50°C., and is not precipitated upon cooling; by evaporation, however, a residue is obtained which has recovered its insolubility in cold water. To redissolve it, it is necessary to heat it to boiling, or allow it to digest for half an hour in a water-bath at 100°C. Alcohol precipitates it and also restores it to its insoluble state. The same result is obtained by congealing the solution in a freezing mixture, in being found when the ice is melted as a white precipitate at the bottom of the vessel. When this substance is mixed with dextrine and glucose, as in the mother liquor wherein these granules are formed, all these properties disappear.

These artificial starch granules give with iodine all the colour reactions obtained with the natural granules as well as those given by dextrine, according to the disposition of their molecules, the result being variable at will. Thus, a dilute solution takes a pure red colour; but when it is concentrated to saturation, iodine gives rise to a violet colour. If iodine be added to a solution moderately diluted, so as to produce a deep red brown colour, and the solution be allowed to evaporate in the open air, it will gradually grow more and more purple; and eventually, when sufficiently concentrated, become of a magnificent pure blue colour. If water be added, the violet colour reappears and in its turn gives place to a pure red.

If, instead of concentrating the red liquid by evaporation, a neutral salt having an affinity for water, such as chloride of calcium, be added, the result is the same. If the blue solution be allowed to stand for twenty-four hours, it deposits a blue-black substance, which is not dissolved by cold water. This precipitate, however, appears to dissolve in water; it does not affect its transparency, and passes readily through a filter, but after a very short time it is again deposited. This is characteristic also of the iodized granulose; from which the author concludes that in both bodies the disposition of the molecules is the same, and that they do not differ in degree of cohesion.

The iodized artificial granulose can, in fact, be destroyed, by a slight elevation of temperature; it enters into solution in the water in which it was suspended, and is then only coloured red with iodine, whilst natural granulose resists a boiling temperature and continues to be coloured blue with iodine. The artificial granules resemble also natural grains of starch, in not being coloured by a small quantity of iodine, the blue only appearing when it is in excess; but if they be triturated in a mortar with a small quantity of iodine, a mass of a pure blue colour is produced.

When starch is incompletely dissolved, either with diastase or boiling acetic acid, the fragments which resist the longest are no longer coloured blue with iodine, but take a tint which varies from yellow to orange-red. The artificial granules give the same colours if their cohesion be augmented, which may be done by dissolving in water and evaporating to dryness.

Diastase decomposes soluble starch in the same manner as natural starch, but much more easily and completely. According to the observations of Payen, Schwarzer, Schulze, and the author, when diastase is caused to act upon starch, all colouration with iodine disappears when the degree of saccharification reaches one-fourth; then, by augmenting the diastase, the saccharification may be increased to one-half, a point that is not passed to any sensible extent; in fact, by his earlier experiments, the author was led to think that it was not possible to saccharify more than one-third of a given quantity of starch by means of diastase. With soluble starch, however, the stoppage of the saccharification at one-third does not occur. The reaction with iodine disappears when it reaches one-fourth; then, if more diastase be added, the production of sugar goes on rapidly until it reaches one-half, when it ceases, as with natural starch.

A widely diffused opinion, introduced into science by Vaegeli regards starch as essentially composed of cellulose mixed with a little granulose. Béchamp has found that dextrine obtained from cellulose has less rotatory power than dextrine from starch. The author prepared dextrine from cellulose by dissolving cotton in strong sulphuric acid. This dextrine was afterwards saccharified with boiling acidulated water, and it was found that during this transformation the rotatory power was not changed. Starch, treated in the same manner, yielded, on the contrary, a dextrine of which the rotatory power had been lowered more than one-half by the saccharification. It follows that the dextrine from cellulose has the same rotatory power as the sugar which is derived from it, which is not the case with that from starch. The author further remarks that all the dextrines of starch sugar have a rotatory power at least double that of the sugar itself.

It is known that glucose freshly dissolved, and especially dehydrated glucose, has a rotatory power at least double that of glucose that has been some time dissolved in a small quantity of water; but this property is not persistent. The author has prepared a dextrine from glucose, by treating that sugar with concentrated sulphuric acid and then with 95° alcohol. This anhydride has also a rotatory power double that of the glucose, and this power is persistent.

The author has not yet obtained sugar from cellulose sufficiently pure to be able to compare it with sugar from starch; but he feels certain that there is no great difference between their rotatory powers; so that their isomerism would not be manifested so clearly as in their dextrines.

The author proposes to investigate whether other sugars which are regarded as identical with glucose—the glucoses of honey and of fruits, diabetic sugar, etc.—present the same kind of isomerism.

* *Comptes Rendus*, vol. lxv., p. 857.

THE OBJECT AND NECESSITY OF A PHARMACEUTICAL EDUCATION.

The following remarks upon the object and necessity of the special education of the Pharmacist are taken from an introductory address, delivered by Professor John M. Maisch, before the Students in the Philadelphia College of Pharmacy, at the commencement of the session, October 1st, 1873:—

Pharmacy has long since been called an art and a science, and this two-fold character becomes more and more evident as the rapid advancement of science determines the equally rapid progress of pharmacy in common with all the industrial arts. The basis of every exact science is *observation;* the experience gained thereby leads, through *ratiocination* on the one hand, to the establishment of fundamental principles, and on the other hand to the generalization of scientific truths; it is a guide to *synthesis* as well as to the opposite method of investigation, *analysis.* Science, therefore, is knowledge obtained by observation and deduction; while art is the practical application of this knowledge, and implies likewise the requisite skill, mental as well as manual, for applying the knowledge correctly and efficiently.

The selection of all medicinal substances of unexceptional purity; the recognition of all adulterations and impurities; the making of chemical and pharmaceutical preparations by the formulas of the Pharmacopœia; the collection, drying, and preservation of all crude drugs; their proper comminution and exhaustion by maceration or displacement; the compounding of physicians' prescriptions with correctness and nicety: all this belongs to the *art* in pharmacy; while the knowledge of the reasons why a prescription should be prepared in a particular way; of the causes which affect the success of percolation; of the influence of heat, moisture, atmosphere, age, etc., upon drugs; of the development in plants and their parts, of the active principle or principles; of the causes of success or failure in carring out any process or manipulation connected with pharmacy, properly belong to *science* in its bearings upon pharmacy.

It is a well known fact that the odour of fresh valerian differs essentially from that which it acquires by age on exposure to the air; this fact is easily explained by chemistry, which has proven that the volatile oil of valerian is gradually converted by the oxygen of the atmosphere into valerianic acid, which possesses a peculiar, strong cheesy odour, the development of which replaces the much milder and different odour of the volatile oil. To detect the grosser adulterations in opium, such as stones, lead bullets and the like, requires no scientific attainments; but to ascertain the true quality of commercial opium, aside from such coarse sophistications, we invoke the aid of analytical chemistry, separate the most important principle, morphia, and determine its exact proportion in the sample before us. Bismuth, in its native state, is found associated with other metals, particularly with silver and arsenic, which are not easily completely separated by the processes adopted for the preparation of this metal on a large scale; chemistry proves the presence of the one by the precipitate occurring in acid solutions with muriatic acid, and the most minute quantities of the other are detected by the formation with nascent hydrogen of gaseous arseniuretted hydrogen, which, under certain precautions, is reduced by heat to the metallic state.

The barks of the different species of cinchona resemble each other in ther chemical constitution, and the bark of the same species is greatly influenced in composition by age, exposure to light and moisture, climate and soil, so that chemistry fails to furnish an infallible criterion whereby the specific origin of a cinchona may be established; the study of the anatomical structure of the bark of the different cinchonas, however, has furnished the means whereby they may be distinguished, or which may become available as soon as the variation in structure, caused by the natural development, shall have been correctly observed through the various phases of growth of each species. Botanical anatomy readily explains the reasons why most of the *Labiatæ* rapidly deteriorate in quality by parting with most of their volatile oil after a comparatively short exposure; and it shows us the cause why some, like rosemary, for instance, retain, even after years, considerable of their volatile oil, although in their unbroken condition they may possess but little odour, which is developed, however, on cutting or bruising the leaves. In the one case the oil cells are either in direct contact with the atmosphere or scarcely protected by a thin layer of epidermis, while in the other case the epidermal layer is heavy and leathery; and a further protection against evaporation of the oil is afforded by the natural folds of the leaf or its revolute margin. The same instrument which reveals to our eyes the minute structure of organisms, the microscope, is often the readiest means to ascertain fraudulent admixtures, and to ascertain the nature of the adulterations; by it the blood corpuscles are revealed, if dried blood has been mixed with such a costly article as musk, and the pollen granules of phanerogamous plants are easily detected, if they have been employed to increase the harvest of the sporules of *Lycopodium clavatum.*

On dissolving a solid in a liquid, cold is produced; natural philosophy teaches us that, in passing from one state of aggregation into another of less density, a certain amount of heat becomes latent, and hence the sensation of cold is felt. The same discipline explains to us the causes why, as a general rule, the solubility of bodies in simple solvents is increased by heat; and where there are exceptions, it calls in the aid of an accessory discipline to furnish an explanation substantiated by experimental proof. Volatile oils volatilize slowly even at an elevated temperature which remains below their boiling point; but they are readily obtained by distilling water from the bruised plants. It is well known that the boiling point of water is far below that of these volatile principles; but the laws of the diffusion of vapours explain satisfactorily the correctness and efficiency of a process which was used for many centuries before it received its true explanation.

In the few instances enumerated, we find ourselves aided by natural philosophy, chemistry, botany, and zoology; in fact, by nearly all the branches of exact science, which either have constructed the delicate apparatus wherewith matter as well as the imponderable forces may be accurately measured; or which employ these instruments in the exploration of a certain domain of nature. The examples given will also, in a measure, point out those disciplines which form the basis of scientific pharmacy, and, consequently, may be taken as an answer to the query: *What should the pharmacist study?* Materia medica, or in its more limited application to the direct wants of the druggist and the pharmacist, pharmacognosy, is botany and zoology applied to drugs; and what may be termed pharmacy proper is really natural history and chemistry applied to preparing into suitable forms the crude materials furnished by materia medica. With but very few exceptions, mineralogy now-a-days yields no drugs. A century ago, the officinal mineralogical drugs were by far more numerous; but since then, the close investigations of chemistry have removed them one after another, substituting in their stead definite compounds of a precise composition; until now but three have been left in our pharmacopœia as representatives of unaltered products of the inorganic kingdom of nature. They are black oxide of manganese, marble, and chalk—the two first named being now not directly used in medicine, but merely employed for the generation of chlorine, carbonic acid gas, and one or two salts of calcium, leaving chalk the only mineralogical medicinal drug which has been retained by the United States and most other pharmacopœias. In a few localities discarded calamine and tutty are somewhat employed yet; but in most places they seclude themselves in the remotest corner of the shop, where they may dream undisturbedly of by-gone days and of the instability of worldly honours; of the times when, in the officine of the pharmacist, they kept company with the agate, amethyst, sapphire, onyx, diamond, and other precious gems. The place which mineralogy once occupied in the drug trade and in pharmacy, is more than filled out by chemistry; and the necessity which formerly required the druggist and pharmacist to become to a certain extent a mineralogist, no longer exists. Mineralogy, as an indispensable part of pharmaceutical education, has entirely lost its importance, although it still holds and for ever will occupy its prominent position as one of the requisites of every liberal education.

The direct products of the inorganic kingdom of nature have almost entirely disappeared from our list of materia medica, and from the crude products of nature only those remain which are of organic origin. They either possess a cellular organization or they are destitute of it, being then merely the secretions or excretions of organized beings. Of the two principal divisions of organisms, those derived from the animal kingdom have been, like the minerals, greatly reduced in number among our officinal articles, until now scarcely half a dozen can be found in our pharmacopœia; of this number, one—hen's egg—represents an embryonic animal; two—cochineal and cantharides—are entire animals; one—isinglass—is a certain tissue, and two—musk and castor—are constituted by peculiar secretions separated in sac-like cavities. These comprise all really organized drugs of animal origin, the remaining non-organized animal drugs being almost exclusively confined to secretions of a fatty or saccharine nature; and of late the secretion of the mucous coat of the animal stomach has been added thereto, but solely with the view of obtaining therefrom the digestive principle, pepsin. How insignificant this number is in comparison to the number of animals, their parts, secretions and excretions, which were highly valued medicines at the same time when the emerald was regarded as a specific against all fluxes and as an antidote against the plague, pestilential fevers, and the bites of serpents and mad dogs, and when the wearing of diamonds was supposed to take away fears and melancholy, and to strengthen the heart. Then not only the blood and flesh of numerous animals of all classes were medicinally employed, but even the hair, hide, urine and dung of many were prepared in various ways, and supposed to possess often miraculous powers in curing disease. The animal kingdom, it seems, is following the mineral kingdom in its relations to medicine as a source of curative agents, of commodities for the removal or prevention of sickness. Musk and castor are gradually becoming scarcer as the human race penetrates more and more into regions hitherto uninhabited; medicinally, cochineal is now regarded as little more than a colouring matter; cantharides are rarely employed except for their rubefacient and epispastic properties, and isinglass with its chemical cousins, the gelatins, is far more frequently employed in the culinary than in the pharmacial art. It shares in this respect the fate of the remaining organized animal drug, the hen's egg, which human instinct prefers using from the breakfast and supper table, to taking it merely as an emulsionizer of disagreeable oils and oleoresins.

There remains but one important source of crude drugs at the present time, namely, the vegetable kingdom. This is destined, by the laws of nature, to assimilate inorganic bodies, transforming them into organic compounds, and thus preparing food for the beings of higher organization. Plants have been medicinally employed in prehistoric times, and, notwithstanding many which have at times been held in high repute, have, on close scrutiny, been found to possess little or no reliable medicinal powers; still the gaps occasioned by the discarding of some have always been filled up by the discovery of others, more reliable than those which have become obsolete owing to their inefficiency, or from other causes have fallen into disuse. Such drugs are furnished by the torrid zone of our globe in almost innumerable numbers; but the more temperate climes of the Northern and Southern hemispheres make valuable additions to this number, and even the icy regions of the subarctic girdle offer their modest share of vegetable products for the benefit of suffering humanity. And as though the offerings of the older sections of our earth were insufficient to meet the varied demands of modern investigation and increasing wants, the antipodal regions of the Australian continent have of late years begun to add to the already valuable stock; and it is not improbable that this at present rather isolated patch of the earth's surface will, in the course of time, send upon the market of the world many important drugs, which may well be able to compete with such as are now obtained from the abodes of civilization in older continents, or from the unexplored and almost unknown regions of central Africa and Asia.

In endeavouring to present to you a short sketch of the proper domain of materia medica, and to indicate the variations in the boundary lines of this discipline, it cannot be my purpose at this time to follow these changes from step to step, and enumerate examples of admitted and discarded articles of materia medica; it is a curious chapter in the history of the human race, and one well worthy of a critical review. But in it, as in all other relations of the human family, we discover the progressive influence of science, before whose light the darkness of ignorance vanishes, and the fog of superstition and fancy is dispersed.

Most important in its influence upon the development of medicine and the selection of curative agents has been chemistry; that science which deals with the relations of the various kinds of matter to each other, whose labours are influencing the investigations of every other branch of natural science, are felt in numerous trades and manufactures, and are of the utmost importance in their bearings upon every-day life. It is not many years ago, when the brines left after the separation of common salt from saline spring or sea water were without value; to-day, immense amounts of bromine are recovered from them, and this element has not only become an indispensable article in many of the arts, but medicine has also appropriated it for the cure of disease; and its compounds, which but yesterday were chemical curiosities, are to-day met with in every officine, and prescribed by every physician. The oily and tarry products of our gas factories had been valueless for a long time, until chemistry converted some of them into brilliant colours of every shade and hue, which are employed in dyeing various fabrics, in colouring candies and sweetmeats, in making fancy inks, etc. The mother liquor from soap had been a waste product, until uses were found for its most important constituent, and glycerin is now such an indispensable agent in pharmacy and medicine, in the arts and the household, that we may well wonder how civilized mankind could get along without an article which in its natural combinations is daily employed everywhere.

Chemistry has made many inroads upon materia medica, and in consequence of the investigations of the former, many articles of the latter have been placed upon the retired list, and others will doubtless sooner or later follow into deserved obscurity. Acidulous fruit, the sorrels and other refrigerant acidulous drugs, have gradually been retired from active service, or are now in most cases merely doing duty as supernumeraries in medicine; since the pure acids, upon which their virtues depend, are being prepared in large quantities and in a condition fit for long preservation. Since the time when the vegetable alkaloids have been discovered, and the processes for their manufacture were perfected, their employment in medicine has continually increased, and, as a matter of consequence, the corresponding increase in the use of the crude material has been prevented. But chemistry is not content with such results even. By processes of substitution it furnishes new remedies of valuable medicinal properties, which seem to be calculated to take the place, wholly or in part, of older remedies. Chloral, crotonchloral and monobromated camphor are among the latest instances of such innovation, and already chemistry prepares a new way for replacing time-honoured medicines in offering *apo*-derivatives of alkaloids, at least one of which, apomorphia, promises not only to hold its place against tartarized antimony and the various mineral emetics, but it threatens even to supersede such a valuable emetic as ipecacuanha, and to render the fears groundless of the gradual extermination of this plant.

In preparing the drugs for the use of the sick, many manipulations have to be performed intelligently and correctly; to enable the pharmacist to perform this task, it is necessary that he should be versed in the principles of natural philosophy, which also form the groundwork for experimental and applied chemistry. The proper constructions of even the more simple apparatus depends upon the correct application of physical laws, no less than the proper performance of all operations and processes. The pharmacist has to judge of the correct shape and the proper material of his mortars, capsules, flasks and retorts; he must be able to examine the correctness and faultless construction of his prescription balance, and to use the same, be it for ascertaining the direct or the relative weight of substances. He must know the effects of air, light, and heat upon each one of the numerous drugs and preparations of his officine in order to enable him to decide promptly how to keep, how to weight, and how to comminute them; and if intended for exhaustion and concentration, the proper vessels have to be selected, maceration and percolation successfully performed, and afterwards evaporation and distillation, crystallization and oftentimes exsiccation, executed in an expeditious manner, involving the least possible loss of time and material, and guarding against each and all the causes for partial or complete failure or deterioration. And if, in consequence of some unavoidable accident, the preparation does not turn out to be in conformity with the wants of the pharmacopœia, the question may have to be decided—not whether it can be patched up to resemble the article for which it was originally intended, but whether the loss, which would be occasioned by its rejection, may in a measure be avoided, either by recovering the valuable solvent or by converting the preparation into some definite compound, the direct composition and purity of which may be ascertained, so as to leave no doubt as to its identity.

It is partly in consequence of the thin population of some sections of our country, that the wholesale druggist has frequently to perform the same laboratory operations, which should never be neglected by the pharmacist. The two callings resemble each other in so far as the handling of drugs and chemicals is concerned; and this involves all the essential questions of their identity, purity and preservation, and, as stated, frequently also the manipulation of pulverization, exhaustion and concentration. Here the similarity of the two callings ends. It is equally important for the druggist as for the pharmacist to be able to recognize jalap, rhubarb, and opium, to distinguish them from inferior qualities, to ascertain their medicinal value, to preserve them from deterioration, and to convert them into the various galenical preparations. The dealings of the druggist are with the pharmacist, and and as the latter stands in his intercourse with the public between the practising physician and the patient, so does he occupy a similar position with regard to the druggist. It is no excuse for the pharmacist, that the physician has prescribed an unusual dose of a poison; he is not justified to furnish the medicine until he shall have ascertained that the physician has prescribed it knowingly and advisedly. It is likewise no excuse for the pharmacist to have received from the druggist any drug or medicinal substance incorrectly labelled; he is not justified to use or sell the same by virtue of its label, but only after he shall have satisfied himself of its identity and purity. It is notorious that, for some time past, large quantities of muriate of cinchonia have been sold in various parts of the United States as the sulphate of quinia of a well reputed French manufacturer. It would be disreputable for any druggist to knowingly sell this fictitious article; but it becomes a criminal act on the part of a pharmacist if he neglects to ascertain that the quinia he has bought, perhaps ten or fifteen cents per ounce under the regular market price, is, in reality, what it purports to be.

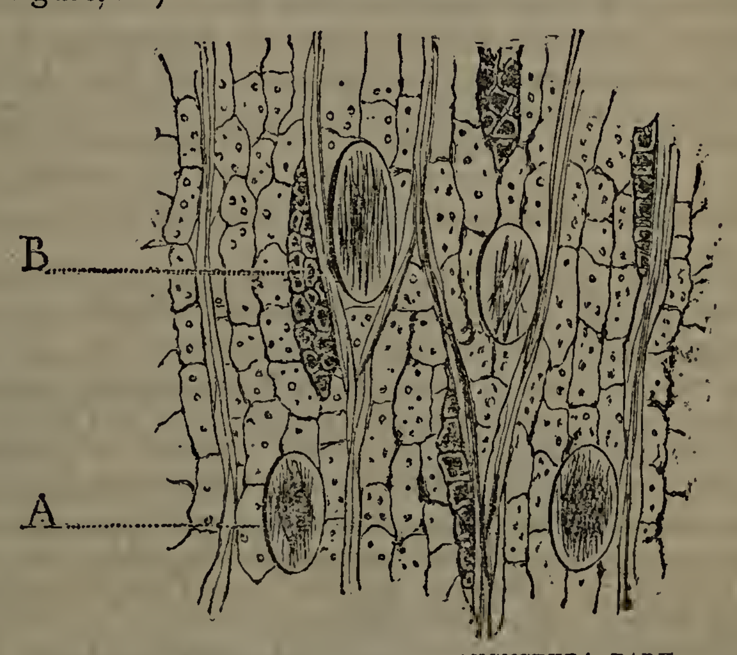
The pharmacist is daily, nay hourly, called upon to perform manipulations and decide upon occurrences which never happen to the druggist. The varied handwritings in prescriptions—often hieroglyphic in form and appearance—the variation in the preparations ordered, the form in which they are exhibited, the doses for adults and infants, the proper methods of combining the prescribed articles, are a few of the incidents which tax the mental faculties of the pharmacist almost incessantly during the business hours. To meet all such difficulties promptly and correctly, it is not merely necessary to know that they may happen. Experience, under correct guidance, is the best, in fact the only reliable teacher in such cases, as in all others requiring mental as well as manual dexterity.

MICROCHEMICAL EXAMINATION OF ANGUSTURA BARK*.

BY P. CAZENEUVE.

The author has been engaged in a microscopical investigation of the physiological characteristics presented by true angustura bark and that of *Strychnos nux-vomica*, and also of the variations in their behaviour when treated with nitric acid. He states that if a transverse section of true angustura bark, cut as thin as possible, be moistened with a little glycerine and examined under the microscope, irregularly scattered groups of much thickened cells will be seen. The false bark, examined under the same conditions, presents two distinct zones of these sclerogenous cells, which are entangled with one another, as may be seen in sections cut in various directions.

The examination may by carried furthur, by taking a very thin tangential section, cut perpendicularly to the medullary rays, placing it upon an object glass, and moistening it with a small drop of distilled water in such a manner that the water overflows the tissue but very slightly when compressed by the upper glass. With a magnifying power of 270 diameters, grains of starch may be seen in the cells of the liber parenchyma; and here and there, in the same tissue, large ovoid cells filled with acicular rhaphides consisting essentially of oxalate of lime. (See figure, A)



TANGENTIAL SECTION OF TRUE ANGUSTURA BARK.
A, Raphides of Oxalate of Lime; B, Cells containing granular matter (Cusparin ?).

There are also groups of rounded cells, the appearance of which recalls the appearance of a perpendicular section of the medullary rays in the woody tissue of dicotyledons in general. These groups of cells (B) contain a granular substance, soluble in alcohol, ether, and acids, and insoluble in alkalis and in water.

If, by means of a glass rod, a drop of nitric acid be applied round the edge of the glass, the acid by capillary action will spread between the two plates of glass to the narrow zone of water which surrounds the tissue. Upon the junction of the two liquids, it will be possible to watch under the microscope the progressive action of the nitric

* Abstract of a paper in the *Répertoire de Pharmacie* for May 10, p. 261.

acid. The oxalate of lime is dissolved, as might be expected. When the granular substance before mentioned, which the author considers to be cusparin, is reached, it melts in each cell, with disengagement of gas, into a reddish liquid, which finally disappears with excess of acid. In the false angustura bark, the action of the nitric acid appears in contact even with the aqueous zone, showing the solvent action of water upon the brucine compound. The colour produced resembles the tint of the hæmoglobin of blood; it spreads rapidly through the tissue, which becomes impregnated with it throughout. By using nitrous vapour upon a perfectly dry section, and avoiding great excess of vapour, which might condense and lead to the diffusion of the colour, the author found that the active principle of the *Strychnos nux-vomica* is contained in the inner liber cells.

If a thin section of the suberous layer of false angustura bark be treated with nitric acid, then dipped in glycerine and afterwards examined under the microscope, it presents rounded cells, empty of contents, and coloured a beautiful green on the sides; this colour is gradually modified and passes definitely to a yellow. The suber of true angustura bark is not modified by the action of nitric acid.

The above-mentioned characteristics of the two barks may be thus summarized: cells containing oxalate of lime are numerous in the true bark, but absent from the false one; the red colouration by nitric acid is localized in the true bark, but general in the false; the suber layer of the true bark is not coloured by nitric acid, whilst that of the false is coloured emerald green.

We are indebted to the kindness of the editor of the *Répertoire de Pharmacie* for the use of the woodcut of the accompanying illustration.

HENNA.

A recent number of the *Belgique Horticole* contains an interesting paper, by M. G. Delchevalerie, upon the henna of the Egyptians, of which the following abstract has appeared in the *Gardeners' Chronicle.*

Two very distinct varieties of the plant are cultivated in Egypt. The first, *Lawsonia spinosa*, differs from *L. inermis* by its very spiny branches and much finer leaves. This is used in making garden hedges; and a fragrant distilled water is prepared from its blossoms. The henna is one of the favourite flowers of the Egyptians, and during its time of blossoming they ornament their rooms with it.

The second form, *L. inermis*, has much larger leaves than the former, and the branches are without spines. It is increased by suckers, and large tracts of ground are closely planted with it under trees in half-shady places. The green stems are cut several times a year, and stripped of their leaves, which are dried and reduced to powder, and thus form an article of commerce under the title of henna powder. The plants, which are cut down almost to the ground, soon throw out fresh shoots, which are cut with a sickle like the first, and the several crops are thus yielded during many successive years.

The culture of henna is easy, and might probably be carried on successfully in Italy and Central France. The variety *inermis* is that which is employed as a dye plant in Egypt. To obtain the flowers the shrub is not pruned, but is allowed to attain the height of two or three metres, when it flowers in the second year. To obtain the colouring principle, however, it is sown or planted very thickly, and the branches are mown as soon as they have reached the height of a metre.

Henna has been in use among the Egyptians from the most ancient times, the leaves having been employed in medicine as well as a cosmetic. The ancient writers mention its astringent and tinctorial properties. Dioscorides mentions it under the name of Cyprus. "The cyprus or ligustrum," he says, "is a tree which bears leaves resembling those of the olive, but longer and softer, and of a greener colour. Its flowers are white and fragrant growing in downy bunches. Its fruit is black, and resembles that of the elder." The name of "cyprus," which the henna formerly bore, doubtless originated from the fact that the Greeks obtained it from the Island of Cyprus, the Cyprians having formerly monopolized the trade in this colouring matter.

Pliny says that the cyprus of the Egyptians is a tree with leaves like those of the zizyphus, seeds like coriander seeds, and white fragrant flowers. The most esteemed and the dearest comes from Canope, on the banks of the Nile; the second from Ascalon in Judæa; and the third (taking them according to the sweetness of their odour) from the Island of Cyprus.

Prosper Alpinus states that invalids procure ease by inhaling the perfume of the flowers of henna, and applying them to the forehead. The Moors, who were well acquainted with this quality, made very extensive use of the flowers for this purpose. The same author says that the natives of Egypt prepared with the leaves a powder called archenda, which was used by the women for dyeing their feet and hands of an orange colour as a means of enhancing their charms. If our women, he adds, would apply this secret to rendering their hair golden they would not need to expose their heads to the heat of the sun and to many other painful methods of ensuring this result. It thus appears that the recent rage for golden hair, like most other fashions, has nothing of novelty to recommend it.

Olivier says that the henna (which the Jews call *hacoper*) furnishes flowers of a penetrating odour, and that an aromatic water was obtained from them by distillation which was employed in baths, and as a perfume in religious ceremonies, such as marriage, circumcision, and the feast of Courban-Bieram. The Jews had also a custom of sprinkling the flowers of henna on the garments of the newly-married.

The ancient Egyptians made use of henna for the purpose of perfuming the oils and unguents with which they anointed the body with a view of obtaining suppleness. They also employed it in embalming, and flowering branches of henna are found in mummy-cases.

Avicenna compares the properties of henna with those of dragon's-blood. He says that its leaves possess the same property of curing ulcers, and that a decoction of them is employed in cases of inflammation and burns, and as a remedy against ulcers of the mouth. Forskal, in his 'Flora of Egypt,' refers to the medical and tinctorial properties of henna. The leaves are dried and reduced to powder, being first mixed with fine sand, which causes them to divide more easily. This powder is used in dyeing, and is an article of considerable commercial importance. It is used in colouring the nails and hands, as also in giving a red tinge to the hair; and it is thus used by old men for dyeing their grey beards. When it is desired to dye the hands with henna, the powder is formed into a paste, and applied during the night. In the morning the hands are washed, and then anointed with oil to give them greater brilliancy. If a browner hue is desired, the juice of unripe acorns is added to the paste.

Bellonias remarks that henna was an important object of commerce among the Turks, who exported it from Alexandria to Constantinople, where the trade in it was considerable. The Grand Seignor, who had a monopoly of this traffic, derived from it annually the sum of 18,000 ducats. At the present day Egyptian henna is largely exported from Alexandria, and, according to the official report, 18,385 cwt. was shipped from this port alone, during the Coptic year 1588 (or 1873), the official value of this quantity being 900,000 piastres.

The colouring principle, which is known as hennotannine, is very abundant in the leaves of henna, and might probably be advantageously used in manufactures. It is still employed by men and women for dyeing the palms of the hands and the nails of the hands and feet of a reddish-orange, the hair and tails of horses and asses are also coloured with it; and it has other uses in Egypt which are of minor importance.

The Pharmaceutical Journal.

SATURDAY, JULY 4, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE IRISH APOTHECARIES' LICENCES BILL.

Upon the second reading of this Bill last Thursday it was referred to a Select Committee, which will afford opportunity for the representation of the various opinions entertained in reference to the proposed measure. As yet we have not heard that the Bill of the Apothecaries' Hall has been introduced into Parliament, but as regards the probability of its success, in case it should come before the House of Commons, it is worthy of notice that it does not seem to command the general support of the Irish Apothecaries, as would appear from the terms of a circular issued on behalf of the Association of Licentiate Apothecaries of Ireland, and bearing the signature of twenty-three apothecaries, located in as many towns in Ireland.

In the drawing up of this circular it seems to have been assumed that the effect of the Pharmacy Bills proposed in regard to Ireland, would be to permit a less educated class than themselves to the same legal rights now enjoyed by apothecaries who, before obtaining their licence, have been compelled not only to have been engaged in practical pharmacy but also to spend four years at professional studies, and pass examinations sufficient to qualify for a licence in medicine. They argue that there would virtually be a disestablishment and disendowment of the existing Irish apothecaries, unfair to them, though it is not contended that the law should continue thus. In fact the circular points out that, although under existing conditions every Irish apothecary *must* undergo this protracted and expensive course of instruction, even to practise pharmacy only, it is the fact that a large number of the licentiate apothecaries do confine their attention entirely to the compounding and dispensing medicines, and are dependent on that business for subsistence.

They therefore seek, in any legislation on the subject, recognition of their vested rights, and compensation from the State for the unnecessary outlay of time, labour, and money to acquire their qualifications in the past, as well as for injury to their interests in the future by the admission of a lower grade of pharmacists to the same privileges, as dispensers of medicine.

It is also suggested that for the future the Apothecaries' Hall in Ireland should grant but one licence, that being a licence to practise pharmacy only. To obtain this license it is suggested that candidates should not be required to attend lectures on, or be examined in, such superfluous subjects as anatomy, physiology, surgery, medicine, or midwifery; but that the standard in subjects essential to a sound pharmaceutical education, such as chemistry, botany, materia medica, pharmacy, etc., should be as high as possible.

Our readers will probably remember that a statement was made some time since, by Dr. Leet, the Registrar of the Irish Apothecaries' Hall, to the effect that there were from twenty-eight to thirty of the most important towns of Ireland, with populations varying from 10,000 to 50,000, where there was no apothecary or other competent person qualified to dispense medicine.* This has long been a common complaint, and it was one of the main reasons assigned for the introduction of some reform of the law relating to pharmacy in Ireland. But the associated licentiate apothecaries dispute the accuracy of this statement. They say that Dr. Leet evidently erred egregiously, since there are not more than sixteen towns in all Ireland whose population (according to the Census of 1861) exceeds 10,000; and they assert, in contradiction of his statement as to the dearth of apothecaries, that in every one of those towns there are a sufficient number of apothecaries for all requirements, so that no inconvenience can arise on that score.

It is further alleged that at present Ireland has no need for Pharmacy Acts, such as those passed in England to promote the efforts of the Pharmaceutical Society of Great Britain towards the raising of the educational standard. It is thought that in Ireland the standard does not require to be raised, but only modified for the future by the omission of purely medical and surgical subjects from the curriculum prescribed.

Especial objection, however, is taken to that clause of the proposed Bill of the Apothecaries' Hall which provides for the registration of persons in business at the time of the passing of the Act, upon their passing a modified examination. It is considered that there is no reason whatever why a druggist in Ireland should not pass through exactly the same ordeal as any other candidate for a pharmaceutical licence; and, on the contrary, it is urged that there is no such dearth of competent dispensers throughout the country as demand the admission of an imperfectly educated class.

Lastly, it i ointed out that druggists have never been legally entitled to dispense medicines in Ireland, and consequently have not entered into business there with such an intention, so that they really do not labour under any disability; and there is, so far, no reason for following the precedent of the English Pharmacy Acts of 1852 and 1868, in regard to chemists and druggists already in business at the passing of those Acts.

A copy of the circular above referred to has been

* See Pharm. Journ., vol. iv. p. 595.

sent to every Irish member of Parliament, together with a letter offering some further remarks on the subject, and requesting them to exercise their vote and influence to secure the objects of the Association of Licentiate Apothecaries of Ireland whenever either of the proposed Pharmacy Acts shall be introduced into Parliament.

CONVERSAZIONE OF THE ROYAL COLLEGE OF PHYSICIANS.

AMONG the scientific *réunions* of the London season the Conversazione of the Royal College of Physicians always holds an honoured place, and we learn from a medical friend that last night's celebration was more than equal to its best traditions.

The President, Sir G. BURROWS, and the Council, received the guests as they arrived; while the "objects of interest" that filled the library were at once varied and attractive. Nearly every department of medico-scientific study, or of antiquarian or artistic interest was represented. Among the former may be mentioned the "Aphloistic Ear-trumpets," contributed by Dr. C. J. B. WILLIAMS; the beautiful and effective "Binocular Microscopes and Anatomical Objects" of Messrs. ROSS and Co.; the hardly less perfect instruments of Messrs. POWELL and LEALAND, Messrs. MURRAY and HEATH, and Mr. BAKER; and the "Cholera-Curves" of Dr. C. MACNAMARA. Among the artistic objects, the contribution of our President, Mr. T. H. HILLS, "the studies of Lions, by the late Sir EDWIN LANDSEER;" the alabaster bust of SCIPIO AFRICANUS, recently found in London; the royal robe, with the diamonds and other precious stones from Coomassie; and the photographs, and specimens of pottery and Wedgwood ware, attracted much attention. Interest of no common kind attached to Sir W. FERGUSSON's contribution of the "Cast of the Left Humerus of Dr. LIVINGSTONE, showing the false joint consequent on the bite of a lion, whereby the body was identified. Some plans of model dwellings for the industrial classes in town and country gave gratifying proof of the advances recently made in one of the first conditions of public health and social regeneration. The international ice manufacturing company exhibited a drawing of the Apparatus for the manufacture of ice by steam power, with samples of ice so made,—an article to which the proverbial heat of London reception-rooms gave a more than theoretical interest.

The number of guests appears to have been unusually large, affording opportunity for many pleasant *rencontres* between professor and pupil, college companions long separated by time and space, and members of other departments of the healing art besides the physician proper.

THE ALLEGED ADULTERATION OF SCAMMONY.

IT will be remembered that at the close of the case of an alleged adulteration of scammony, which was dismissed by Mr. VAUGHAN, the magistrate sitting at the Bow Street Police Court on the 17th June,* the hearing of two other cases was adjourned for a fortnight. When these cases were called in Court on Wednesday last neither prosecutor nor defendants answered, and it would therefore appear that the cases are abandoned. If this be the case, the course was resolved upon at the last moment, since, in reply to an application at the office of the Strand Board of Works on the previous day it was stated that the prosecution was to go on.

* PHARM. JOURN., June 20th, p. 1020.

THE PRESCRIBING OF "PATENT MEDICINES."

SPEAKING of the recent action for libel in connection with the supply of a "fever tincture" to the Government, for use on the Gold Coast, the *Medical Times and Gazette* says,—

"We only refer to this case to deplore the custom of, in a certain sense, compelling medical men to have recourse to secret and unknown remedies for the treatment of disease when such a complete collection of well-known and well-tried medicines is available for the physician's use. The result of this practice, however, appears to be, that on the outbreak of a war such as that which has happily just terminated on the Gold Coast, a well-intentioned but hurtful pressure is brought to bear on the authorities; and, in deference to the strongly urged suggestions of its advocates, a secret remedy (of the composition of which the medical officer who is to employ it knows nothing) is sent out to be tried upon our sick soldiers, though we should fancy few medical men of the present day in civil practice would care to avail themselves of its services. In the present case, moreover, the testimony of the lamented Dr. LIVINGSTONE was adverse to the efficacy of this nostrum, though supported by high medical authority, as a remedy for the treatment of African fevers. In one of his books of travel, the Doctor states that on the recommendation of a friend he had tried it, and found the result unsatisfactory.

"With a comprehensive British Pharmacopœia, periodically revised by the most competent men of the time, we trust that the day of nostrums and secret remedies will soon pass away for good, and that the progressive enlightenment of the people generally will eventually conduce to their utter extinction."

It may also be mentioned that whilst Dr. HASSALL was under examination by the Select Committee on the Adulteration Act he was incidentally asked what he thought of the sale of "patent medicines." He replied that "patent medicines" were patent evils, since they were prescribed as secret remedies by persons ignorant of their composition; and whilst in some cases they might do good, it was quite probable that in many cases they did harm.

ENGLISH MEDICINE SEEN THROUGH CHILIAN SPECTACLES.

LAST week we had the opportunity of putting before our readers the opinion of a South American pharmaceutical authority upon English pharmacy. The *Times* telegrams of Monday last enable us to supplement this with a view of English medicine from the same quarter of the globe. It appears that the British Minister at Santiago has been making complaints that English physicians are prevented from practising in Chili. To this the Dean of the Medical Faculty in Chili has replied that the medical knowledge imparted in England is greatly inferior to that required before the degree of Doctor of Medicine could be acquired in Chili, and that it would, therefore, be unjust to allow British physicians to practise with less competence than was required from Chilian physicians. Whether this be the voice of self-interest, self-satisfaction, or conscious superiority, we are glad that neither of these elements operated to produce so harsh a criticism of English pharmacy from the neighbouring country.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, July 1st, 1874.

MR. T. HYDE HILLS, PRESIDENT, IN THE CHAIR.

MR. A. BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Greenish, Hampson, Owen, Radley, Robbins, Sandford, Savage, Shaw, Stoddart, Sutton, and Williams.

The minutes of the previous meeting were read and confirmed.

THE INAUGURAL ADDRESS IN OCTOBER.

The SECRETARY read a letter from Mr. R. Giles, of Clifton, accepting the invitation of the Council to deliver the address to the students in October next.

THE BRITISH PHARMACEUTICAL CONFERENCE.

The PRESIDENT read a letter from Mr. Carteighe, thanking the Council, on behalf of the sub-committee of the British Pharmaceutical Conference for their offer to make arrangements for a Conversazione, and stating that the fifth of August appeared to be the most suitable evening for the purpose. It was resolved accordingly that the Conversazione be held on August 5th.

The President, Vice-President, Mr. Sandford, and Mr. Williams, were appointed a Committee to make the necessary arrangements for the reception and entertainment of the members of the British Pharmaceutical Conference in August next, and also to arrange for the Conversazione to be held on the same occasion.

DIPLOMAS.

The following, being registered as Pharmaceutical Chemists, were respectively granted a diploma, stamped with the seal of the Society :—

Cortis, Arthur Brownhill.
Feaver, John.
Luff, Arthur Pearson.
Smith, John Jacob.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

David, John ....Kenfig Hill.
Harvey, John William............Croydon.
Luff, Arthur Pearson ....South Kensington.
Smith, John Jacob ....Islington.

Chemists and Druggists.

Gossop, George Kennington ...Great Grimsby.
Rowell, Robert ....South Shields.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Gardiner, William Eustace......Peckham.
Lyon, James ....Kingsland.

Modified.

Evans, Gomer ....Bala.

The following, having passed the Minor Examination, were elected "Associates" of the Society :—

Billinge, Mark ....Hyde.
Bulcock, Joseph Henderson......Clitheroe.
Burley, William ....Edinburgh.
Cooper, Henry.......................London.
Davey, John Trimble ....Exeter.
Draper, James William ....Malmesbury.
Dunlop, Thomas Hall.............Newcastle-on-Tyne.
Durnford, John.......................Maidstone.
Gardiner, Bruce Hubert John...London.
Gradidge, William Ivimey........Andover.
Hammond, William Henry......Northampton.
Heslop, George.......................Newcastle-on-Tyne.
Husband, John Cecil..............Berwick.
Lee, Joseph...........................Southport.
Mac Farlane, Peter.................London.
Pechey, Thomas Pollard..........Birkenhead.
Phillips, James Wilson............Broadstairs.
Ridley, Edward Henry............Manchester.
Riley, Charles Reynolds ... .London.
Shaw, William Burton............Scarborough.
Stevenson, Henry Ernest.........Southport.
Strickland, Robert Brewster.....Manchester.
Tame, Thomas.......................Oxford.
Thompson, Charles.................Bedworth.
Walter, George William.........Horncastle.
Wheatly, Arthur William ......Thame.
Winn, John Christopher ....Darlington.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society :—

Axford, John William.............Coventry.
Campbell, Robert Saul........... Manchester.
Cleminson, John Hetherington Beverley.
Cocker, Justus John.. ....Over Darwen.
Hall, Edwin ....Horncastle.
Hallawell, William..................Manchester.
Heaton, Wilmer Everard.........Colne.
Holmes, Alfred John.............Preston.
Larder, Herbert ....Horncastle.
Parker, Thomas ....Preston.
Sadler, William......................Margate.
Smithurst, John......................Nottingham.

Several individuals who had neglected to pay their subscriptions in proper time were ordered to be restored to their former status on payment of the subscription for the current year and a fine equal to half the amount.

THE PRELIMINARY EXAMINATION.

The SECRETARY reported that, in consequence of the large number of candidates coming up for the Preliminary Examination, he had made inquiries as to getting accommodation elsewhere, and found that, if desired, the examination hall of the Incorporated Law Society, in Chancery Lane, could be obtained at an expense of ten guineas each examination. Several members expressed a strong opinion that it was very undesirable to hold the examination away from the Society's own House unless absolutely unavoidable ; and, after some discussion, it was referred to the House Committee to make such arrangements, and incur whatever expense might be necessary, for the purpose of the examination, authority being given to close the Library on that day if necessary.

FINANCE.

The report of this Committee, recommending the payment of various accounts and salaries, was received and adopted.

BENEVOLENT FUND.

This Committee had met and considered several applications for relief; and they recommended the following grants to be made :—

To the widow of a registered chemist and druggist, residing in London, aged 57, £10.

To a registered chemist and druggist at Halifax, aged 60, who was a member of the Society from 1841 to 1872, now an invalid and unable to attend to business, £10.

The name of Mary Ann Dodd, of London, and that of Thomas Parker, of Halifax, were ordered to be put on the list of "approved candidates for annuities."

Two other cases were deferred for further investigation.

Some discussion arose as to the desirability of adding fresh names to the already published list of approved candidates, but the general opinion appeared to be that all eligible candidates should be placed upon the list, and the report and recommendations of the Committee were therefore adopted.

Mr. Radley suggested that, in future, the list of approved candidates should not be published until complete, in order not to give one candidate an advantage over another. He therefore moved, and Mr. Owen seconded—

"That the regulations of the Benevolent Fund be reconsidered by the Benevolent Fund Committee."

Mr. Hampson said he should like to know what required reconsideration before voting for this resolution.

Mr. Shaw suggested that any such action should be deferred until after the approaching election.

The President said there could be no harm in the Committee reconsidering the regulations and reporting to the Council.

The Vice-President suggested that the Committee should report in November, and with this addition the motion was agreed to.

Mr. Owen reported that he had been successful in his efforts to obtain the election into the London Orphan Asylum of one of the children of Mrs. Stockman, towards which purpose £20 was recently voted from the Benevolent Fund. He desired to add, in order to show that the wholesale trade were ready to assist any real case of distress, that Messrs. Baiss Brothers had come forward and given him £20 for the same purpose.

Library, Museum, and Laboratory.

The Committee recommended the purchase of the following books for the use of the Library:—

Smith's 'Pharmaceutical Guide,' 2nd Edition.
Waring's 'Therapeutics.'
Parrish's 'Practical Pharmacy,' 4th Edition.
Dr. J. C. Thorowgood's 'Students' Guide to Materia Medica.'
Pettigrew's 'Physiology of the Circulation in Plants, in Lower Animals, and in Man.'
Babington's 'British Botany,' 7th Edition.
Notcutt's 'Handbook of British Plants.'
Mohr's 'Commentar zur Pharmacopœa Germanica.'
Wanklyn's 'Water Analysis,' 3rd Edition.
Black's 'General Atlas,' last Edition.

The Librarian had reported that, from May 13th to June 17th, he had issued 48 vols. to the provinces under the recent regulation; that the average attendance in the Library had been 18 in the day, and 5·38 in the evening. Professor Bentley had reported that there were 43 pupils attending his special class at the Botanical Gardens; Professor Redwood, that there were 26 Students in his class; and Professor Attfield, that there were 33 pupils now at work in the Laboratory.

A letter had been received from Professor Attfield, stating that the Chemical Society proposed advertising their Journal in several periodicals, and suggesting that the Pharmaceutical Society would be doing a graceful act in inserting such an advertisement gratuitously. The Committee, therefore, recommended that one advertisement per month be inserted for six months, not exceeding a quarter of a column in length, provided space could be found for it.

The Secretary reported that about fifty original letters from the late Dr. Pereira to Dr. Guibourt, of Paris, had been presented to the Society by the late Dr. Guibourt. The Committee recommended that these letters be carefully bound and placed in the Library.

The report and recommendations of the Committee were received and adopted.

Female Students.

The Committee had also before it a letter from Professor Attfield, stating that two lady students who were attending the classes of his colleagues, asked permission to attend the Laboratory. They were already devoting a good deal of time to study in the British Museum, and were desirous of working for some time in the laboratory; to which, after giving due consideration to the subject, he saw no reason to object, if the Council were willing.

Mr. Hampson then moved:—

"That the reply to Professor Attfield's letter be to the effect that this Council has no objection to his receiving lady students in the Laboratory, and that the House Committee be requested to make the necessary arrangements."

His views upon this question were so well known, that he would not trouble the Council with many words upon it. They had already admitted ladies to the classes of the other Professors, the Act of Parliament admitted them also to examinations, and now the two ladies applied to be enabled to obtain the best instruction in practical chemistry, which would fit them for passing their examinations. He believed this course was really of more value than almost any other, inasmuch as it brought them face to face with principles and chemical conditions, and it was now for the Council to consider whether they should refuse them admission. He thought, to be consistent, this could not be done, as the applicants had already been admitted to the lectures. Remembering also that they were empowered by Act of Parliament to examine ladies, they ought to give in that institution equal opportunities for obtaining the requisite knowledge. It was simply a matter of justice and fair play, which he hoped would be conceded.

Mr. Greenish seconded the motion, saying he thought it was really a question for Professor Attfield, under whose management the Laboratory was placed; and as Professor Attfield saw no difficulty, he did not think the Council should interfere. There was only one question which the House Committee would have to consider, namely, making certain requisite arrangements.

The Vice-President said he did not desire to oppose Mr. Hampson's view, but he asked him to withdraw the latter part of the resolution, authorizing the House Committee to make the necessary arrangements, because it was just possible that such arrangements as they could make, would not be satisfactory; and if lady students were to be admitted to the Laboratory it would be well perhaps at the commencement of the ensuing session to make such provision for them as would be creditable to the Society.

Mr. Hampson said he had no objection to withdraw the latter part of the resolution.

Mr. Sandford thought that such an important matter ought not to have been brought forward without notice having been given. It would entirely contradict the resolution to which the Council came some time ago—not to admit ladies to the laboratory—which was a very different thing to admitting them to the lecture-room. He happened to know that Mr. Brown, who was not present that day, agreed with him in that, and in thinking that having ladies in the laboratory would be a source of mischief; there was not proper accommodation for them. When Professor Attfield mentioned the matter, he said he had found a room which would answer the purpose of a retiring room, but in so doing he thought the Professor had gone rather beyond his province. It had been decided that ladies should not be admitted as members of the Society, and when the question came before the General Meeting, the opinion was overwhelmingly against it, and even against encouraging them to enter the trade at all. For his own part he felt that it was not a fit vocation for women, as they were exposed to certain things which he should be extremely sorry that any woman in whom he felt an interest should be exposed to. He hoped, therefore, the motion would be refused.

Mr. Savage said that as Professor Attfield saw no objection to the ladies being admitted, and he for one quite coincided with him, he thought they ought to accede to his application. It was a matter of some importance, and although two years ago certain resolutions were passed, there had been a great deal of progress since then. As far as the accommodation was concerned, that was for the ladies themselves to consider. His opinion was that they would be a restraining influence on the young men, and that their presence would be productive of great benefit.

Mr. OWEN said it was only a question of time, they must come round to it at last. Still he thought that notice of motion should be given.

Mr. HAMPSON said a reply was required to the letter of Professor Attfield, or he should not have brought it forward; indeed, he knew nothing of the matter until the previous day.

Mr. BETTY objected to the way in which this question was brought forward; a side issue being raised on a letter, of which no previous notice had been given, thus taking the Council rather by surprise. He did not think they ought to be called upon suddenly in that manner to give a reply to a letter on such an important question. If it came before them in a more regular way, no doubt it would be received more favourably; and he would, therefore, suggest to Mr. Hampson to withdraw the motion for the present, and let the matter of the admission of ladies come before them in a legitimate and fair manner for discussion and decision. He would not speak on the merits of the question at present, but, personally, he should wish to vote that the ladies be admitted and that the professor be not restricted in the selection of his pupils.

Mr. SUTTON thought, as a matter of order, Mr. Betty was quite right, though he felt very strongly that the application in itself was right and proper.

Mr. WILLIAMS said Professor Attfield brought this question forward at the fag end of a Committee meeting, and really desired the Committee to consent to his admitting the ladies into the laboratory without bringing the matter before the Council at all. The Committee, however, declined such a responsibility, and requested the Professor to submit the matter to the Council. It appeared to him they could only refuse the application at present, whatever course might be pursued hereafter.

Mr. BAYNES also urged Mr. Hampson to withdraw the motion, seeing that no great injustice could be done, as only about one month's instruction could be obtained by these applicants during the present session.

Mr. HAMPSON said it was true he had not given notice of motion in a formal manner, and he was rather gratified to find that the application came in the ordinary way, without raising the whole question and unduly enlarging it. He thought, coming in the way it did, it simply showed it was a *bonâ fide* application to receive instruction, and that the Council would have been disposed to listen to the application, rather than require a formal notice of motion to be given for reopening a question which had been considered so startling. However, he would rather withdraw the motion than lose it, because he believed there was a great principle of fairness and impartiality involved in it. He would, therefore, withdraw it for the present, and give notice of motion to bring it forward on a future occasion.

Some discussion then ensued, as to what reply should be sent to Professor Attfield.

Mr. WILLIAMS moved, and Mr. BETTY seconded the following motion:—

"That Dr. Attfield be informed that the Council cannot, under the present arrangements, agree to the reception of lady students in the Laboratory of this Institution."

To this an amendment was moved by Mr. SAVAGE, and seconded by Mr. HAMPSON:—

"That the further consideration of admitting ladies to the Laboratory be postponed, and, in answer to Dr. Attfield's letter, he be informed of the fact."

The amendment being put to the vote, the following was the result:—

For—Messrs. Baynes, Greenish, Hampson, Owen, Savage, and Sutton.

Against—Messrs. Atherton, Betty, Radley, Robbins, Sandford, Shaw, Stoddart, and Williams.

The President and Vice-President were present, but did not vote.

The amendment was therefore lost, and the motion was then put and carried.

LAW AND PARLIAMENTARY.

The report of this Committee stated that they had received copies of the Apothecaries' Licences Bill, and the Pharmacy Bill for Ireland proposed by the Apothecaries' Company of Ireland. The first Bill would extend some of the powers of the Pharmacy Act to Ireland, and enable the Pharmaceutical Society to appoint a Board of Examiners in that country. The Committee recommended that these bills be carefully watched; and the Secretary now reported that the first named Bill had been referred to a Select Committee of the House of Commons.

The Committee had also had laid before it certain correspondence from the Society's Solicitor, in which he narrated his failure to obtain sufficient evidence to enable him to commence proceedings against a person who was alleged to have contravened the provisions of the Pharmacy Act.

The report was received and adopted.

HOUSE.

The report of this Committee dealt principally with estimates which had been obtained for doing certain painting, etc., to the Society's premises. It was received and adopted, and the necessary work ordered to be proceeded with.

APPOINTMENT OF PROFESSORS, ETC., FOR THE ENSUING YEAR.

Professor Redwood was re-appointed Professor of Chemistry and Pharmacy.

Professor Bentley was re-appointed Professor of Botany and Materia Medica.

Professor Attfield was re-appointed Professor of Practical Chemistry.

Mr. Holmes was re-appointed Curator of the Society's Museum.

LOCAL SECRETARIES.*

The following gentlemen were appointed Local Secretaries for 1874-75, in the towns to which their names are appended:—

Aberdare	Thomas, Watkin Jones.
Aberdeen	Davidson, Charles.
Abergele	Ellis, William.
Aberystwith	Davies, John Hugh.
Abingdon	Smith, William.
Altrincham	Holt, William Henry.
Andover	Madgwick, William B.
Ashby de la Zouch	Johnson, Samuel E.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Banbury	Linnett, Samuel S.
Banff	Ellis, Bartlet.
Bangor	Griffiths, John E.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow in Furness	Steel, Thomas.
Basingstoke	Sapp, Arkas.
Bath	Pooley, John Carpenter.
Bedford	Cuthbert, John M.
Belper	Ashton, John.
Berwick	Carr, William Graham.
Beverley	Hobson, Charles.
Bewdley	Newman, Robert.
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Blackburn	Pickup, Thomas Hartley.
Blandford	Groves, Wellington E.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, George.
Boston	Marshall, Robert.
Bradford (Yorkshire)	Rimmington, Felix W. E.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other Towns as contain not less than Three Members of the Society or Associates in business.

Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner.
Bridlington	Forge, Christopher.
Bridport	Tucker, Charles,
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, William W.
Buckingham	George, Sirett.
Burnley	Thomas, Richard.
Burslem	Blackshaw, Thomas.
Bury St. Edmunds	Portway, John.
Buxton	Barnett, Alexander.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Cross, William.
Cardigan	Jones, John Edwards.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard M.
Carnarvon	Jones, John.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Grindley, William.
Chesterfield	Greaves, Abraham.
Chichester	Long, William Elliott.
Chippenham	Westlake, Bernard.
Christchurch	Green, John.
Cirencester	Mason, Joseph W.
Cockermouth	Bowerbank, Joseph.
Colchester	Manthorp, Samuel.
Congleton	Goode, Charles.
Coventry	Wyley, John.
Crewe	McNeil, James Norton.
Darlington	Robinson, Alfred Francis.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Frost, George.
Devizes	Portbury, George Henry.
Devonport	Dickerson, Henry.
Dewsbury	
Diss	Gostling, Thomas Preston.
Doncaster	Dunhill, William W.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	
Dumfries	Allan, William.
Dundee	Hardie, James.
Durham	Sarsfield, William.
Eastbourne	Provost, James A.
Edinburgh	Mackay, John.
Elgin	Robertson, William.
Evesham	Dingley, Richard Loxley.
Exeter	Delves, George.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, W. F.
Fareham	Franklin, Alfred.
Flint	Jones, Michael.
Folkestone	Cadman, Daniel Charles.
Frome	Harvey, William Brett.
Gainsborough	
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Curtis, A. A.
Gosport	Hunter, John.
Grantham	Gamble, Richard.
Gravesend	Smith, Geo. Mason.
Greenock	Fraser, Charles.
Grimsby, Great	Palmer, Enoch.
Guernsey	Arnold, Adolphus.
Guildford	Martin, Edward W.
Haddington	Watt, James.
Halifax	Dyer, William.
Hanley	Jones, Charles.
Harrogate	Davis, Richard Hayton.
Hartlepool, West	Jackson, William G.

Harwich	Bevan, Charles F.
Hastings & St. Leonards	Jameson, William Edward.
Haverfordwest	Williams, William.
Helston	Troake, Marler Hamilton.
Hereford	Jennings, Reginald.
Hertford	Lines, George.
Heywood	Beckett, William.
Hirwain	George, John Evan.
Hitchin	Ransom, William.
Horncastle	Elsey, John.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Baines.
Huntingdon	Provost, John Pullen.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut, John, jun.
Kendal	Severs, Joseph.
Kidderminster	Hewitt, George.
Kilmarnock	Borland, John.
King's Lynn	Atmore, George.
Knaresborough	Sindall, John William.
Knutsford	Silvester, Henry Thomas.
Lancaster	Wearing, William.
Launceston	Eyre, Jonathan Symes.
Leamington	Jones, Samuel Urwick.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Cooper, Thomas.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lincoln	Maltby, Joseph.
Liskeard	Eliott, Samuel.
Liverpool	Abraham, John.
Loughborough	Paget, John.
Louth	Hurst, John B.
Ludlow	Cocking, George.
Lyme Regis	Thornton, Edward.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.
Maidenhead	Walker, Robert.
Maidstone	
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Hardy, George.
Malvern, Great	
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Knight, Alfred.
Market Harborough	Bragg, William B.
Marlow	Foottit, Charles Miller.
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Robson, James Crosby.
Montrose	Burrell, George.
Neath	Hibbert, Walter.
Newark	Harvey, John.
Newbury	Davis, Frank Pratt.
Newcastle-under-Lyme	Cartwright, William.
Newcastle-on-Tyne	Proctor, Barnard S.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Pearman, Henry.
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Atherton, John Henry.
Nuneaton	Iliffe, George.
Oldham	Hargreaves, Henry Lister.
Oswestry	Smale, Richard Bill.
Over Darwen	Hargreaves, William Henry.
Oxford	Prior, George T.
Paisley	Hatrick, William.
Pembroke	John, David William.
Pembroke Dock	Andrews, Charles.

Penrith	Kirkbride, William.
Penzance	Cornish, Henry Robert.
Perth	Dandie, David.
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Balkwill, Alfred P.
Pocklington	Cundall, Robert.
Poole	Penney, William.
Portsmouth, etc.	Rastrick, J. L.
Preston	Hogarth, William.
Ramsgate	Morton, Henry.
Reading	Hayward, William G.
Redditch	Mousley, William.
Reigate	Forbes, William.
Retford	Baker, William.
Richmond (Yorks)	Thompson, John Thomas.
Ripon	Colley, John.
Rochdale	Taylor, Edward.
Rochester	Harris, Henry William.
Rothesay	Duncan, William.
Runcorn	Whittaker, William.
Rugby	Garratt, John C.
Ruthin	Bancroft, John James.
Ryde (Isle of Wight)	Wavell, John.
Rye	Plomley, James F.
St. Albans	Martin, Henry Gilham.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, Samuel Ralph.
Scarborough	Whitfield, John.
Selby	Colton, Thomas.
Shaftesbury	Powell, John.
Sheerness	Rayner, William.
Sheffield	Wilson Edward.
Shepton Mallet	Cottrill, Gilbert Jones.
Shields, North	Williamson, James.
Shields, South	Mays, Robert J. J.
Shipley	Dunn, Henry.
Shoreham	Barker, John.
Shrewsbury	Cross, William Gowen.
Skipton	Foxcroft, Elijah.
Slough	Griffith, Richard.
Southampton	Dawson, Oliver R.
Southport	Walker, William Henry.
Spalding	Rhodes, Frank.
Stafford	Averill, John.
Stalybridge	Brierley, Richard.
Stamford	Patterson, George.
Stirling	Duncanson, William.
Stockport	Lowndes, Hervey.
Stockton-on-Tees	Brayshay, William B.
Stoke-on-Trent	Adams, Jonathan Henry.
Stourbridge	Bland, John Handel.
Stratford-on-Avon	Hawkes, Richard.
Stroud	Blake, William F.
Sudbury	Harding, James John.
Sunderland	Nicholson, John J.
Swansea	Brend, Thomas.
Tamworth	Allkins, Thomas Boulton.
Taunton	Prince, Henry.
Tavistock	Gill, William.
Teignmouth	Cornelius, Joseph.
Tenby	Walkinton, Wm. Marmaduke.
Tewkesbury	Allis, Francis.
Thirsk	Thompson, John.
Tiverton	Havil, Paul.
Tonbridge	Wibmer, Lewis Michael.
Torquay	Smith, Edward.
Truro	Serpell, Samuel.
Tunbridge Wells	Howard, Richard.
Ulverstone	Radnall, William Henry.
Uttoxeter	Johnson, John Borwell.
Wakefield	Taylor, John.
Wallingford	Payne, Sidney.
Walsall	Highway, Henry.
Wareham	Randall, Thomas.
Warrington	Woods, Joseph Henry.
Warwick	Pratt, Henry.
Watford	Chater, Edward Mitchell.
Wednesbury	Gittoes, Samuel James.
Wellington	Langford, John Brown.
Wells	Manning, Richard James.
Westbury	Taylor, Stephen.
West Bromwich	Pershouse, Edward.
Weston-super-Mare	Rich, Thomas.
Weymouth	Groves, Thos. Bennett.
Whitby	Stevenson, John.
Whitehaven	Kitchin, Archibald.
Wigan	Dunsford, Samuel.
Winchester	Powell, Edward.
Windsor	Russell, Charles J. L.
Wolverampton	Brevitt, William Yates.
Woodstock	Sant, George.
Worcester	Witherington, Thomas.
Worthing	Coitis, Charles.
Wrexham	Edisbury, James Fisher.
Wycombe	Furmston, Samuel C.
Yarmouth, Great	Poll, Wm. Sheppard.
York	Davison, Ralph.

The British Pharmacopœia.

Mr. Hampson, in accordance with notice of motion, moved as follows :—

"That this Council respectfully urges upon the General Medical Council the desirability of having appointed a Joint Pharmacopœia Committee of Physicians and Pharmacists, for the purpose of preparing any future edition of the British Pharmacopœia, or preparing any further Addendum to the present issue.

"This Council also suggests that it would be an equitable and desirable arrangement, if the Council of the Pharmaceutical Society were to nominate the Pharmaceutists on the proposed Joint Pharmacopœia Committee."

He said that for a considerable time before the recent excitement took place, which culminated in the reading of a certain paper at one of the evening meetings, he had formed a strong opinion upon this subject, and had come to the conclusion that the Society occupied a very anomalous position with regard to the Pharmacopœia. He felt that he was treading upon rather delicate ground, and that he was under some responsibility in introducing this subject, because medical gentlemen were as much concerned in the matter as himself ; but still he felt persuaded it might be treated in such a manner that no one's feelings could be hurt by it. He was exceedingly desirous that the relations between the medical profession and themselves should be most cordial ; but they had a duty to perform in this matter, and they ought not to shrink from it. The Society represented Pharmacy, and it was their duty when a subject of this sort came forward, to speak out plainly their convictions. Some twenty or twenty-five years ago it was the function of the various colleges to prepare Pharmacopœias, and in so doing they received assistance from pharmacists then living. Since then, however, a great development had taken place in pharmacy, partly in consequence of increased activity in the trade and partly from legislation. It was only necessary to refer to the character of their own examinations, and to the proceedings of the Pharmaceutical Conference, to show what a development had taken place in pharmacy, and he considered the time had come when pharmacists ought to take an equal place on the Pharmacopœia Committee. At the same time it would be absurd for pharmacists to interfere with the medical part of the question, such, for instance, as determining doses or what medicines should be admitted; but it being their duty to be acquainted with practical pharmacy, they were in a better position than medical men to frame the processes of a Pharmacopœia. His proposition therefore was, that there should be a joint Committee, consisting partly of medical men and partly of practical pharmacists, who should have an equal voice and an equal legal responsibility in the matter. Their present position was eminently unsatisfactory, and pharmacy was not yet recognized as it ought to be. When the British Pharmacopœia was prepared, the Society had been requested to *assist*, but not as principals, and that was the position he maintained they ought to fill. They were in this respect far behind all Continental nations, where pharmacists met physicians on equal terms and took part in the formation of the national Pharmacopœias. Without going at all into details, he was quite prepared to maintain that neither the Pharmacopœia nor the Addendum was satisfactory, and this was of the more importance, because the Pharmacopœia when published was virtually the law of the land. By their own Act of Parliament they were bound to make preparations according to the formularies of the British Pharmacopœia, which was an unfair position to place them in, when some of the processes where known not to be practicable. As had been shown in the recent scammony case, the Pharmacopœia was accepted as the standard, but in some cases that standard might be put too high, and thus the honest trader might suffer. He would say, in conclusion, that he wished the resolution to be simply an expression of opinion, and as such it would have some weight on the future action of the Medical Council.

Mr. Greenish, in seconding the motion, said this was one of the most important matters that could be brought before the Council, and the question really divided itself into two parts, whether they ought to be more fully represented on the Pharmacopœia Committee, and secondly, whether this was the proper time to move in the matter. In the first place, he thought no one could take the British Pharmacopœia, leaving the Appendix out of the question, and consider it satisfactory. He had written to M. Soubeiran, of Paris, who informed him that the French Codex was framed by a mixed Committee of medical men, botanists, and pharmacists. He had ascertained also that in Belgium there was a mixed Committee of medical men and pharmacists; in Holland the Committee was composed of four pharmacists, two botanists, one chemist, and two medical men; and in Austria, pharmacists were groaning under something like the same difficulty as their English brethren, but they were not contented, and were endeavouring to make an alteration. In North Germany, he heard from Dr. Carl Schacht that the Committee for the last Pharmacopœia was composed of five pharmacists, two professors of chemistry, one of botany and pharmacognosy, one of pharmacy, and three medical men; and he thought some such arrangement as that was more likely to result in a good work being produced. On the second point, whether this was the proper time to move in the matter, he thought, as the Appendix had just been issued, and considerable attention had been drawn to the matter, they might very well go to the Medical Council and present their claim to be more fairly represented.

Mr. Savage doubted whether it was desirable to urge this proposition further at the present time. Their relations with the medical profession had hitherto been those of amity and kindness, and he should be sorry to do anything to cause an alteration. At one time the medical men did this work entirely by themselves; more recently they had taken into their councils one of the professors of the Society, who had consulted some leading pharmacists, and he thought it would be better to let things go on quietly, and trust to the spontaneous action of the Medical Council, without exciting any feeling of jealousy on their part.

Mr. Betty said if anything was necessary to convince him of the wisdom of Mr. Hampson's resolution, the remarks of Mr. Savage would have done so. The very fact that the medical profession had done something, showed that they were alive to the necessity and importance of it; and it was only in accordance with their own dignity as pharmacists, to say openly that they claimed to have an official position on the Pharmacopœia Committee. No doubt it was done with the best motives, but the semi-private way in which the recent Addendum was sent to a few pharmacists was not consistent with the best interests of the Society, nor with the position of pharmacy in England. If the thing were to be done at all, it ought to be done in the proper way by the Society.

Mr. Williams said this was a very delicate question. It was the function of the Medical Council to appoint a Pharmacopœia Committee, which should have the exclusive right of saying what should be included in the Pharmacopœia and what not. At the same time, he thought their Society should have the power of appointing a sub-committee as a right, rather than as a matter of favour, who should be responsible for the accuracy of the processes, and the tests and characters of the various drugs and preparations enumerated. But he was not certain they would not be taking upon themselves a responsibility which might not always be pleasant, because they would, perhaps, meet with blame which now rested upon other shoulders. Manufacturers, when applied to for the best method of producing certain preparations, very naturally declined to give them, and the members of the Committee would be therefore left to their own devices to find out the best processes they could. In doing so they would not be always successful, and any members of the Pharmaceutical Society who might hereafter be placed on such a Committee would perhaps find themselves in a very difficult position. Still, he thought an important principle was involved; and that they should, as a Society, ask the Medical Council to accord them this privilege, especially seeing that they were bound, under the Acts of Parliament, to take the Pharmacopœia as their standard, and they therefore ought to have some voice in its formation. To give one instance, in the new Addendum, acetic ether was given with a sp. gr. of ·910, at which, as far as his experience went, it could not practically be made by following the directions given in the Pharmacopœia.

Mr. Shaw said this was a very delicate matter, and a considerable amount of personal feeling had been lately generated in connection with it. Therefore, though he sympathized very strongly with the wishes and views enunciated in the resolution, he thought it would be better to postpone the matter until they had reason to believe that a new edition or an Addendum was in contemplation, which probably would not be the case for some years to come.

Mr. Betty suggested that the second paragraph of the resolution should be omitted, which would leave the Medical Council more at liberty to make their own arrangements.

Mr. Sandford said it was very difficult to oppose Mr. Hampson when he said that pharmacists should be well represented on any Committee that was to compile a Pharmacopœia. But at the same time it must be remembered that, by the Medical Act, the General Medical Council, and they alone, were empowered to prepare and issue the Pharmacopœia. When they were preparing the first edition in 1864, a much larger Committee was appointed, and pharmacy was more fully represented on it; but still the result was a very imperfect production, as was shown by another edition being issued three years afterwards. When the edition of 1867 was being prepared, a Committee of only five members was appointed, and the Pharmaceutical Council was asked to send a representative to it. Dr. Redwood was selected for this office. He had given a great deal of attention to it, and everybody admitted that that edition was a great improvement on its predecessor. He fully agreed that pharmacists ought to be more fully represented, but he thought there was a feeling of irritation at the present moment in the minds of some of the Medical Council which had been engendered by recent discussions at the evening meetings, and which would be against their conceding what was asked; he therefore earnestly urged Mr. Hampson to withdraw his resolution for the present.

The Vice-President, though agreeing with Mr. Hampson, thought it undesirable that they should move in the matter at that time.

Mr. Hampson said he felt a great difficulty in declining to withdraw his resolution after what had been said, but he thought it would be a mistake to do so. He saw no reason why medical men should feel aggrieved at pharmacists forming and expressing the same views which they would themselves express in a like position. As to the prospect of an Addendum or new Pharmacopœia not being required for some time, he did not think that was any reason for delay, because the future Pharmacopœia was already beginning to be formed in the minds of medical men and pharmacists. There were certain errors palpable in the present one, which it would be advisable for such a joint Committee as he proposed to consider and discuss before it was necessary to issue a new Pharmacopœia. It would be the duty of such a committee to gather information, not only from English but from foreign pharmacists, and the more time they had for experimental processes the better.

Some further discussion ensued and several suggestions were made as to verbal alterations in the resolution; eventually, on the suggestion of Mr. Sandford, it was unanimously agreed to in the following terms :—

"That this Council respectfully urges upon the General Medical Council the desirability of associating more practical pharmacists with any Committee which may be appointed for the purpose of preparing any future edition of the British Pharmacopœia, or any further Addendum to the present issue. This Council would be prepared to nominate such pharmacists in the event of the Medical Council agreeing to their proposal."

It was then moved by Mr. Williams, and seconded by Mr. Owen—

"That a copy of the resolution just agreed to, be forwarded to the General Medical Council with the respectful compliments of the Council of the Pharmaceutical Society."

Payment of Scrutineers.

Mr. Greenish, in accordance with notice of motion, then moved—

"That, in future, Scrutineers be paid at the rate of two guineas each for their services."

After some discussion, however, as the general feeling of the Council seemed to be against such an innovation, the motion was withdrawn.

Report of the Board of Examiners.

The Board of Examiners for England and Wales reported that during the month of June they held six meetings, and examined as follows :—

June, 1874.

England and Wales.

Examinations.		Candidates. Examined.	Passed.	Failed.
Major	June 16th and 16th	5	4	1
Minor	June 17th	21	11	10
"	" 18th	27	9	18
"	" 24th	26	9	17
"	" 25th	25	11	14
"	" 26th	28	6	22
		—127	— 46	— 81
Totals		132	50	82

Certificates received in lieu of the Preliminary Examinations :—

3	University of Cambridge
2	" " Oxford
3	College of Preceptors
1	Royal College of Surgeons (England)
1	" " (Ireland)
10	

Deputation to the North British Branch.

A letter from Mr. Mackay, the Honorary Secretary of the North British Branch, was read, intimating that the first examination in the Society's new rooms in Edinburgh, would be held on the 28th inst., and inviting the Council to appoint a deputation to be present on that occasion.

It was resolved—

"That a deputation, consisting of the Vice-President, and Messrs. Cracknell, Carteighe, and the Secretary, be appointed to attend the examination at Edinburgh on the 28th inst."

EXAMINATIONS IN LONDON.

June, 1874.

Present—17th and 18th—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

24th and 25th—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

26th—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 24th on behalf of the Privy Council.

MAJOR EXAMINATION.

Five candidates presented themselves. *One* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists :—

*Luff, Arthur Pearson................Old Brompton.
Smith, John Jacob ....Yeovil.
Feaver, John..........................Truro.
Cortis, Arthur Brownhill............Worthing.

MINOR EXAMINATION.

One hundred and twenty-seven candidates presented themselves for the Minor examination. *Eighty-one* failed. The following *forty-six* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

*Riley, Charles Reynolds ....London.
*Heslop, George ....Newcastle-on-Tyne.
Frank, John...........................Whitby.
Maynard, George Christopher ...Moreton-in-Marsh.
Ashley, Henry ....Gravesend.
Lee, Joseph ....Southport.
Equal. { Bulcock, Joseph Henderson ......Clitheroe.
Fowler, James ....Barton-under-Needwood.
Davey, John Trimble ....Exeter.
Newitt, Herbert Henry ....Bicester.
Draper, James William ....Malmesbury.
Equal. { Bayston, George Coryndon.........Guildford.
Gradidge, William Ivimey ....Andover.
MacFarlane, Peter ....London.
Lamble, John Alfred ....Kingsbridge.
Frost, John ....Abergavenny.
Buckle, James.........................Malton.
Jones, Charles William ....Ashby-de-la-Zouch.
Gardiner, Bruce Hubert John ...London.
Arnold, Harry Shaw ....Cwm Avon.
Equal. { Durnford, John ....Maidstone.
Husband, John Cecil ....Berwick-upon-Tweed.
Dale, George Edgar.................Colchester.
Thompson, Charles ....Bedworth.
Strickland, Robert Brewster ......Manchester.
Equal. { Cripps, Ernest Henry ....Devizes.
Winn, John Christopher ....Darlington.
Equal. { Bodger, John William ....Peterborough.
Stevenson, James ....Cirencester.
Equal. { Longmore, Henry Edward.........London.
Stevenson, Henry Ernest ....Southport.

* Passed with Honours.

	Tame, Thomas	Oxford.
Equal.	Cooper, Henry	London.
	Dee, Walter	Cheltenham.
	Steele, Stephen	Steyning.
	Hammond, William Henry	Northampton.
Equal.	Lancaster, William George	Sheffield Moor.
	Porter, Albert	Abingdon.
Equal.	Pechey, Thomas P.	Birkenhead.
	Shaw, William Burton	Scarborough.
Equal.	Billinge, Mark	Hyde.
	Ridley, Edward Henry	Manchester.
Equal.	Phillips, James Wilson	Broadstairs.
	Rogers, Sydney	Newport Pagnell.
	Stacey, Henry George	London.
	Walter, George William	Horncastle.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination :—

Certificates of the University of Cambridge.

Hawthorne, Charles Oliver.........Stafford.
Sadler, William ....Margate.
Smith, John Ord ....Scarborough.

Certificates of the University of Oxford.

Cleminson, John Hetherington ...Beverley.
Fazan, Charles Herbert...............Colchester.

Certificates of the College of Preceptors.

Beilby, Alfred Emanuel ....Sutton-in-Ashfield.
Green, William James ....Yeovil.
Wilson, William Alexander.........Birmingham.

Certificate of the Royal College of Surgeons of England.

Hancock, Edwin..........................London.

Certificate of the Royal College of Surgeons of Ireland.

Clements, Henry Joseph ....St. Leonards.

Proceedings of Scientific Societies.

NEWCASTLE-UPON-TYNE CHEMICAL SOCIETY.

At the meeting of the above Society, on the 6th March, a paper, of which the following is an abstract, was read on :—

The Position of Professional Chemists, as affected by the Adulteration Act.

BY PROFESSOR MARRECO.

The author, having premised that his main object was to elicit the views of the society, as representing the chemical opinion of the North, proceeded to suggest the following propositions as a basis for discussion.

1. That in the interest alike of the buyer, the seller, and the profession, it is desirable that only thoroughly competent persons should be appointed to the new office of public analyst.

2. That there is at present no recognized standard for the "competent knowledge," medical, chemical, and microscopical, required by the Act.

3. That until some recognized examination exists, giving some guarantee of the knowledge of these various subjects required by professional analysts, this state of things cannot be remedied.

4. That it is desirable that such an examination under proper supervision should be instituted, and that only persons holding such diploma should be considered as duly qualified for the post of public analyst.

The President said, the questions which Professor Marreco had raised was a very large one. Was he prepared with any suggestions for the solution of the difficulty?

Professor Marreco said, of course the details of the solution were things with which they had nothing to do. He did not care how constituted or where situated, but let them have a Board before whom a man could give clear evidence that he ought to call himself a professional chemist. A man might make as many analyses as he pleased; but he ought not to be eligible for the post of public analyst, unless he could bring forward some evidence of training and a standard of knowledge, in the same way as a man who was medical officer to a workhouse. If you appointed a man at £30 a year as medical officer to a workhouse, he had to produce distinct evidence of his training and qualification; and what he contended for was this, let everybody be required to show proofs of these things before he was eligible—before he was, in the language of the Act, "duly qualified."

The President said, if he gathered Professor Marreco's meaning rightly, what he suggested they should do was to let a formal expression of opinion from that society proceed to the proper quarter.

Professor Marreco—I don't go to that. We have had quite enough of expressions of opinion lately.

The President said, it could not be denied that in some of the late cases brought under prosecution, the issues had been scandalous. From his own observations and reading, he quite agreed with every word which Professor Marreco had said; and thought that what he aspired to was not at all impossible to attain. It would simplify the matter extremely if there were any regular degree, conferred by any English University or acknowledged place of higher Education, such, for instance, as the degree of Bachelor of Science. The higher degree would follow, as a matter of course, or any other degree which might be named for that degree, were it *primâ facie* qualification; and those who could not show any such degree, might be obliged to undergo a certain examination before a Board properly constituted by authority. He thought that so long as chemists only sought to act from the commercial point of view in private practice, the public government should not in any way interfere with them; it would, in his opinion, be much more inconvenient if they did, and he did not approve of it at all. In that case you must say *caveat emptor!* If the merchants would go to chemists not competent to make an analysis, it was their own fault: they should go to somebody who had given warranty of his ability in the matter. But this was not a question of a merchant sending an analysis to a chemist to be performed, but was a question of a whole district depending upon the services of a publicly appointed officer. When it was a question of magistrates deciding cases, and perhaps punishing a man, if not by the infliction of a heavy fine yet with the entire loss of his credit, then he thought it was an extremely awkward thing that the magistrates should be obliged to rely upon the judgment of people who, in themselves, did not give the least warranty that their evidence was trustworthy. In the case of a very wonderful story, Gibbon says—the Arabian historian vouched for the truth of it; but who vouched for him? He thought this was a case which only too often occurred now: the public analyst vouched for a certain analysis, but nobody vouched for his competency to make it. He, for his part, cordially agreed with the suggestion which Professor Marreco had thrown out; only he would like it to take some more tangible form, because he thought a simple expression of it in their minutes would not go very far.

Mr. Glover thought Professor Marreco had hit the right nail on the head when he laid the blame of the present appointment of chemists upon the appointing body. They all knew the popular opinion was, that if a man had had a medical training he was therefore a chemist. Now, they knew that nine-tenths of medical men knew very little of chemistry. With all respect to their medical knowledge, their training did not give them that knowledge of chemistry which fitted them to be analysts. It was a branch of science distinct entirely from that of medical practice; and therefore, if there was an appointing board to be connected with some of our scientific institutions—if in Newcastle, for instance, the appointing board was connected with the College of Science—he had no doubt a properly qualified analyst would in all cases be appointed. At least, there would be evidence that he would be in possession of knowledge which would fit him to perform the very delicate duties of an analyst of articles of food. As long as the appointment was solely in the hands of town councils and local boards, it was utterly hopeless to expect that any properly qualified person would be appointed.

Mr. Pattinson quite agreed with Professor Marreco that some kind of certificate or diploma of competency in these matters should be obtained. The Adulteration Act had been launched upon the country when the country had not been prepared with a sufficient number of people competent to examine food, drugs, and drinks. He thought that something more than could be obtained in any of our present educational institutions was required in this instance. Probably it would be best to have a special training college or school, where the precise subject of the detection of adulteration should be specially taught, and a certificate of competency given to such people as passed certain examinations. If that were done, it would be some considerable safeguard for the public against the mistakes we had heard of recently.

Mr. Berkley thought that town councils and local boards were the proper persons to appoint public analysts. But at the same time, if they had diplomas as medical gentlemen have, the local boards or town councils, who were generally composed of men who had common sense, would select good men. Analysts who pretended to analyse food and drink should have diplomas or certificates of competency. He believed that a great many of those who professed to be analysts knew nothing whatever about the subject.

Mr. Proctor would like just to confirm what Mr. Pattinson said about the necessity of having a distinct educational board. Professor Marreco had alluded to the sort of education which pharmaceutists are put through; and he knew, from having passed that examination himself some years ago, and also from members of the Board of Examiners, that the examination of pharmaceutists was certainly not sufficient to qualify a man to hold a position as public analyst. Of course, there was very great diversity in the amount of chemical knowledge and of medical knowledge which pharmaceutists possessed. It depended altogether upon how they pursued matters after they passed the examination. No body at present existing had the sort of machinery at command which was necessary to bring men to the very great diversity of information which was requisite in a public analyst. A man might be a manufacturing chemist, or a theoretical chemist, and still want that species of technical knowledge which was a part of pure chemistry. Men were wanted combining chemical and other knowledge, and they were not to be got at present. In this particular line of business, he supposed nothing could be done until time was given for the school to grow, and the students to be produced.

The President said that time had been given for the training of a sufficient number of adulteration chemists, if he might so call them; meanwhile they ought to take the very best substitutes they could find, namely, gentlemen who evidenced in some way a good general knowledge of chemistry; and they should insist that only such men should have the right to be elected public analysts. If that were done, he thought nearly everybody would agree that the local authorities should retain the power of appointing the local analysts, but with the restriction that they must only elect them from a number of duly qualified persons. He would throw out a suggestion, that the Society petition Parliament to pass a law according to which the local authorities should only appoint public local analysts from such persons as had either obtained a degree in an English college ———

Professor Marreco: No, no. The appointments should be made from persons who have received a special training.

Mr. Richardson said the difficulty was that a sufficient number of qualified men did not exist.

Mr. Pattinson said the qualification would have to be defined.

Mr. Richardson said any resolution passed now should simply tend to suppress the office of public analyst.

Professor Marreco: Because you cannot get the very best men, that is no reason why you should take the worst.

Mr. Proctor said, that, in the absence of other evidence, the best evidence of the fitness of a man for that post was the higher graduation of the Pharmaceutical Society.

Professor Marreco: I quite agree with you.

Mr. Proctor: It was far better than any medical evidence they professed, and he fancied it embraced ground more valuable than that which they had got in a college of pure technical chemistry. A knowledge of drugs and of things analogous to drugs was so important, that although the pharmaceutical chemist was very deficient in pure chemistry, his knowledge of drugs compensated, to a certain extent, for it, and this covered the ground better than any other which they possessed at present. At the same time, he would not at all recommend the Government to appoint pharmaceutical chemists. It seemed hopeless to do anything at present, till there was established a school which would educate such chemists.

Mr. Richardson said it was not only necessary to have qualified men as chemists, but also more knowledge of chemistry was required on the part of magistrates, local boards, and corporations. Until education on the matter was more diffused, which would not be for many years, he suspected it would be more or less a *fiasco*. We would go on in our old English fashion of learning to do a thing by doing it, instead of learning to do it.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Apothecaries' Licences Bill.

On Thursday, June 25, the Apothecaries' Licences Bill was read a second time and referred to a Select Committee. On Wednesday, July 1, the Select Committee were nominated as follows:—Mr. Errington, Sir Michael Hicks Beach, Sir John Gray, Mr. Corry, Dr. Cameron, Mr. Ion Hamilton, Dr. O'Leary, Mr. Bruen, Mr. Sheil, Mr. Leslie, and Mr. Chaine.

Juries Bill.

The consideration of the Juries Bill, which has been recommitted, has been deferred till Monday next.

Poisoning by Carbolic Acid.

On Tuesday evening, Dr. Lankester, the coroner for Central Middlesex, held an inquest at Upper Holloway, touching the death of Mr. Thomas John Baker, aged 53, a surgeon. Mrs. Elizabeth Baker stated that her husband, the deceased, who suffered from dyspepsia, went to bed on Saturday night about half past 12, but could not go to sleep. About two o'clock witness was awakened by hearring the deceased moving about the room. In reply to her questions he said he had taken something, and was afraid it was poison. There was a bottle on the drawers labelled "Carbolic acid—poison;" the deceased frequently went into his surgery for a draught. Two or three days before, he had told her that he had mixed some potash and brandy to take. She suspected that he went for this in the night, and took up the wrong bottle in mistake. There was no light in the surgery. Dr. G. O. Spencer stated that he was called to the deceased, whom he found quite dead. On making a *post-mortem* examination, he found the cause of death was poisoning by carbolic acid. The jury returned a verdict of "Death from misadventure."—*Times.*

Scammony.

Sir,—The recent trial of Mr. Cocks, at Bow Street, is one, in many respects, to be regretted, and serves to show how cautious analysts should be in granting certificates, in regard to alleged adulterated drugs. The specimen of powdered scammony was a fair sample; but with every respect for Dr. Attfield's authority, I am sorry to say he failed to give the correct data, as will be seen. In reply to the question: "Do you say that this article we are summoned for is a genuine scammony or adulterated?" *Dr. Attfield*:—"It is a genuine scammony, it is not adulterated." According to his own analyses, he obtained, what he called, 76 per cent. of resin, and from a perfectly dry powder 80 per cent.

The former shows 24, the latter 20, per cent. of extraneous matters—as chalk, starch or flour, earth, moisture, etc. How then can the scammony in question be said to be pure, and up to the highest standard of the British Pharmacopœia, which gives 80 to 90 per cent. of resin removable by ether? That it was a good sample of scammony cannot be denied; but the standard in the B. P. was not given correctly. Dr. Attfield was bound to give the B. P. standard, and no other. When asked: "As the highest to be expected," Dr. Attfield says: "80 per cent. is mentioned in the B. P." Now, Mr. W. Squire, in his examination, quotes from a paper by Maltass, 88·2 per cent. of resin; Christison found 82 to 83 in dry specimens; and Marquart 81·25. My object in writing is to show that the B. P. standard is not too high for pure scammony. Why was 80, and not 90 given? In future prosecutions, I hope the magistrates will demand the production of the Pharmacopœia, and not be satisfied with the statement of any witness. Had this been done, it is open to conjecture whether the prosecution would have failed or broken down as it did. In regard to Mr. Piesse, I hope, in future, he will consult our standard authority. Had he done so, he would not have fixed the standard of scammony at 75 to 80. So long as we have a standard authority, I hold that witnesses are bound to acknowledge it, and no other, and to quote from it correctly.

Henry Brown, L.R.C.P., L.R.C.S., etc.

Northallerton, 29th June, 1874.

Analysis of Milk.

Sir,—In your issue of the 13th inst., you reported a case of Milk Adulteration, in which I had certified a sample of milk as adulterated with half an ounce of salt per gallon. Several inquiries have been made of me with reference to that result.

Will you, therefore, allow me to state that the salt, reported as an adulteration, was in excess of the quantity present in genuine milk.

The ash of genuine milk contains an average of ten per cent. of its weight of chlorine.

Calculating this as chloride of sodium, it will equal about 86 grains per gallon. The variations from this quantity are within moderate limits. I have not yet met with a milk, known to be genuine, in which it exceeded 110 grains per gallon. In the sample in question the ash of 100 grains bulk, which weighed 1·08 grains, contained ·468 grain chloride of sodium, calculated from the chlorine found—equivalent to 328 grains per gallon or 218 grains in excess of the maximum.

It is said that salt is added to milk during the hot weather in order to keep it sweet, and cause the cream to rise quicker; and although I cannot vouch for this, yet I have on several occasions found a considerable excess of salt in milk adulterated with water.

G. W. Wigner.

79, Gt. Tower Street, E. C.,
29th June, 1874.

Excessive Labour in Pharmacy.

Sir,—There must be very many, who, like myself, have read with gratification the letter which appeared from a "Country Major Associate" in your last.—It is seldom that we see so plain and straightforward an avowal of fact from an employer, and as such, it must have additional interest. It would be hard to believe that his is an exceptional case, for if so, why is it that on all hands—in town as well as in the country—we hear of the scarcity of assistants? I am sure, if the truth were told, that the most fertile source of reduction in our ranks is nothing else but "long-hours." There are many who point to the examinations as being the primary cause, but, speaking as a young man, I cannot believe it. In the examinations themselves, there is little to fear—provided that there were a few hours in each day that every assistant, or apprentice, could claim as his own; and, if such were the case, we should hear less of the enormous per-centage of failures.

It may be very pleasant to think that ours is an honourable calling, and that we are in a position in which we may be of very material aid to our neighbour, by helping to alleviate his sufferings, and so on; but charity commences at home, and certainly there is no inducement for a young man to enter the lists when, on inquiry, he finds that he may think himself blessed if he gets twelve hours' work only per day; whilst, possibly, in the majority of cases, he would find that he was expected to serve his master fourteen hours of the day, and to find what time he could out of the remainder of the twenty-four for rest, recreation, and study.

Leaving remuneration out of the question entirely, for we all know what that is, are there many who are fit for studying after a hard day's work? And yet numbers amongst us have no other time for this purpose, and then only to be constantly interrupted by those persons who will persist in coming after business hours, however paltry their wants may be. We may get up early in the morning, it is true, and I dare say there are many who could tell of good results from such a practice; but is it to be expected of the future generation that their whole existence shall be passed in harness? Are they to rise early and get to their books, go from their books to the shop, and from the shop back to their books again? It seems so, or there would have been some great change in our hours of business ere this. That the change is practicable there is not the shadow of a doubt, and it would only be another illustration of the maxim that "unity is strength."

There are some who, in defence, might say that when they were young they had to work many hours more than we have at present; but I would remind these that the old system was found lamentably deficient, that new regulations have had to be enforced by Parliament in the matter of education, and that unless concessions are granted, and those very speedily, too, as far as regards "time," we may look in vain for apprentices and assistants in sufficient number to keep pace with the demand.

A "Major" Student.

"*A Student.*"—No; the reaction is as follows:—

$$3\,Cu'' + 8\,HNO_3 = 3\,Cu(NO_3)_2 + 2\,NO + 4\,H_2O.$$

Cupric nitrate. Nitric oxide.

W. Symons.—We believe that efforts have been made on different occasions to secure such an arrangement, but they have always been unsuccessful.

J. Williams.—Your complaints of breaches of the Medical Act—which we are indisposed to credit—would be more appropriately addressed to the Registrar under that Act. Your other statements appear to be merely expressions of your own opinion, which are hardly of sufficient importance to pharmacists to warrant their being printed.

A. Mitchell.—(1) *Orchis incarnata.* (2) *Orchis maculata.*

N. J. L.—Questions 1, 2, and 4 relate to questions of law, which we are not competent to answer. (3). The 23rd section of the Pharmacy Act, 1868, to which probably you refer, was repealed by the "Act to Amend the Pharmacy Act, 1868," 32 and 33 Vict., cap. cxvii. (5) The person mentioned has passed the preliminary examination, but is not now "a registered apprentice or student of the Society."

H. Young.—The subjects are usually literature and science, and full information may be obtained from any of the universities granting such degrees.

"*Dandie Dinmont.*"—See the regulations for the appointment of naval dispensers in the Pharm. Journ. (vol. iii., p. 364), or the Society's Calendar, and the correspondence respecting army dispensers in the Pharm. Journ., vol. iv., p. 79.

Communications, Letters, etc., have been received from Mr. Sturton, Mr. W. Symons, Mr. Wilson, Mr. T. H. Williams, Mr. Baildon, Dr. F. Porter Smith, Mr. Druce, "An Associate," "Seven o'clock," "Nasus," W. T. E., X. Y. Z.

RHAMNUS FRANGULA
versus
RHAMNUS CATHARTICUS.

BY CHARLES UMNEY.

As the constant demand for novelty is a great inconvenience to pharmacists, no undue encouragement should, on this account, be given that may in any way tend to multiply unnecessarily our already too lengthy materia medica.

But there are occasions when it is found that certain preparations, although they may have become remarkable for their longevity, should be superseded by others for manifest reasons.

One is often tempted to think that if compilers of Pharmacopœias were to be interrogated why such and such preparations had been left again and again in their accustomed place, they would probably reply that they had heard little or nothing against them, and that they had accordingly permitted the formulæ to remain where they found them.

No better illustration can be found of the foregoing than the syrup of buckthorn of the British Pharmacopœia.

It is not here contemplated to dispute that the berry of *Rhamnus catharticus* is devoid of purgative principle, or is not an active cathartic, but rather to show that now certainly, and in all probability for years past, the manufacture of the juice and syrup of buckthorn has been of a most suspicious and unsatisfactory character, indeed, has been a thorough sham

Syrup of buckthorn first appeared in the London Pharmacopœia of 1650 ("*Syrupus De Spina Cervina*"), but the administration of buckthorn was by no means a novelty at that period, for a decoction of the berries had been used at a much earlier date as a cathartic.

The formula referred to may, with advantage, be reproduced here, if it be only to show that in the 17th century the manufacture of syrups was thoroughly understood.

SYRUPUS DE SPINA CERVINA.

℞

Baccarum Spinæ Cervinæ, Mense Septembri collectarum . . . . *q.v.*
Contundantur in pila lapidea, et exprimatur succus
Succi expressi pars quarta primum per se evaporet in balneo
Dein libris ejus duabus injice Sacchari purissimi uncias sedecim
Coque in Syrupum, quem condias
Mastiches
Cinnamoni
Nucis Moschatæ
Sem. Anisi tenuissime pulveratorum ana drachmis tribus.

This formula was again given in the Pharmacopœia of 1668, but was modified in 1677 by the very sensible omission of the mastich, also of the anise fruit, cinnamon and nutmeg only being used.

This alteration seems to have been approved for the next half century (P. L., 1682, 1721, 1724), but in 1746 the fashion was in favour of ginger, which was added to the other spices, and was used (P. L., 1763) until 1788, when pimento was ordered, and the cinnamon and nutmeg omitted.

This formula has been maintained, and been given a place in each London Pharmacopœia during this century; and, finally, in our British Pharmacopœia, we find it side by side with those modern syrups that are considered to represent the elegant pharmacy of the 19th century.

Buckthorn Berries.—The British Pharmacopœia does not describe (as it almost invariably does in other cases) the characters by which these berries may be known and distinguished from others similar in appearance. It is possible occasionally to select berries from those that are sold for preparation of the expressed juice that have not the four-celled and four-seeded characteristic of *Rhamnus catharticus* The compilers, no doubt, correctly premised that few pharmacists would prepare the juice for themselves. This, unfortunately, is too true, and herein is the whole source of error.

Buckthorn berries are by no means plentiful. The London market is supplied from (amongst other places) Buckinghamshire, Hertfordshire, and also from Wiltshire, but the quantity sent is exceedingly small.

The simplers and others who collect these berries prefer to supply the juice (?) as expressed by themselves, rather than dispose of the ripe berries for such purpose.

Buckthorn Juice is described by the British Pharmacopœia as "the recently expressed juice of the ripe berries of common buckthorn."

It is just possible that the compilers had no opportunity of examining an authentic specimen of the juice, and therefore did not venture a description of the characters by which it could be distinguished from spurious liquids resembling it.

Of course, true buckthorn juice should at the proper season be met with in trade; it is difficult, however, to find a specimen of purchased juice that will compare with that expressed by oneself. I have never been successful during the past ten years, in satisfying myself that from two to five volumes of water had not been added in the several specimens I have examined.

My own observation shows that ripe buckthorn berries, when expressed in the early autumn, will produce about 45 to 50 per cent. of juice, which has the following characters when freshly prepared:—Sp. gr. 1·070 to 1·080; of a green colour, which gradually changes into red, on account of the acidification of the mucilaginous and saccharine matters, of which considerable quantities are present, accompanied by a copious deposition of an inulin (?) like substance.

After the lapse of a year, the specific gravity will have decreased, on account of this change, to about 1·035.

A recent examination of trade specimens gave the following results, and indicated that the same sophistication is still going on, which has been common for years past.

Succus Rhamni, of trade (1874)

	Sp. gr.
1.	1·005
2.	1·004
3.	1·007
4.	1·007
5.	1·075 (true juice)
6.	1·035 (true juice, 1 year old.

These specific gravities indicate that water is the chief ingredient in the Succus Rhamni of trade, and the deductions from above figures would point to a ratio of about six parts of it to one of true juice.

In buckthorn syrup the juice is so disguised by the spices and sugar that it is no easy matter to speak authoritatively upon the genuineness of a specimen.

Any one however, who has had an opportunity preparing a syrup direct from the berries, cannot fail to identify a spurious preparation.

Of course, however, it must follow that, if true buckthorn juice is such a *rara avis*, so also is buckthorn syrup.

The question now arises, how is all this to be remedied. It is true we have an act specially framed for detecting and punishing adulteration of drugs as well as food and drink, but in this particular case (as in many others equally absurd) I much question if any one could be found who would seriously take up the matter.

Would not any one venturing upon it become an object of ridicule to the medical profession and pharmacists generally, for wasting time upon such frivolity?

The remedy is in the rejection of *Rhamnus catharticus*.

The *Rhamnus frangula* bark enumerated in the materia medica of recent German and other Pharmacopœias, although somewhat a novelty in this country, still has been experimented upon by Baildon, Giles, and others, and is said to be a most valuable aperient. This bark can be easily procured at all seasons, is most easy of manipulation, and from it a syrup (if we must have a syrup) can be easily made.

Having experimented, with a view to prepare an elegant and reliable liquid preparation of *Rhamnus frangula* bark, I am of opinion that a fluid extract containing an equivalent of one drachm of the bark in one fluid drachm, would be most acceptable.

Percolation of the finely-powdered bark by dilute alcohol, with a *modus operandi* similar to that of the United States Pharmacopœia for fluid extracts, produces a preparation elegant in appearance, but open to one objection, viz., the precipitation of much resinous matter upon dilution with water.

Decoction and subsequent evaporation to the required bulk, seem to be best adapted for the production of a concentrated fluid extract that shall be miscible with water in all proportions.—Thus :

Fluid extract of the Bark of Rhamnus Frangula.

(ʒj = ʒj fl.)

Take of

Bruised Bark of Rhamnus Frangula	1 pound.
Alcohol (·838)	4 fl. ozs.
Distilled water	q. s.

Boil the bark in three or four successive portions of water until exhausted. Evaporate the decoctions by the aid of a water bath to twelve fluid ounces, or a sufficiency, so that the product to which the spirit has been previously added, shall, when filtered, measure *sixteen fluid ounces.*

Although I am not much impressed with the advantages to be gained by the administration of a syrup, still if such be required in order to replace the now officinal syrup of Rhamnus catharticus, I should suggest the following formula :—

Syrup of Rhamnus Frangula.

(10 grs. to fl. ʒj.)

Take of

Bruised Bark of Rhamnus Frangula	3 oz. 287 grs.
Sugar	1 pound
Water	a sufficiency.

Boil the bark in successive portions of water until exhausted. Evaporate the decoctions by a water bath to ten fluid ounces or a sufficiency, so that the solution shall, when the sugar has been dissolved in it by a gentle heat, finally measure one pint, or weigh one pound ten and a half ounces. (Spec. grav. 1·320.)

This new addition of *Rhamnus frangula* to our materia medica has, I imagine, been for some time known to, or even been brought to the notice of the Pharmacopœia Committee for consideration.

As some considerable time must necessarily elapse before the re-issue of another British Pharmacopœia, it would be advisable to give the foregoing, or some similar preparations, a trial; indeed, any investigations bearing upon pharmacy would very much lessen the labours of those who are entrusted with the compilation of the work, and, to a great extent, preclude those disparaging remarks which we are all more or less inclined to make should any imperfect formulæ be introduced into our national Pharmacopœia.

Laboratory, 40, Aldersgate Street, E.C.

THE APPENDICES OF THE BRITISH PHARMACOPŒIA.

BY WALTER G. SMITH, M.D., DUBLIN,

Fellow and Censor K. and Q. C. P. I.; Examiner in Materia Medica, Q. U. I.; Assistant Physician to the Adelaide Hospital.

(Continued from p. 3.)

VOLUMETRIC SOLUTION OF BICHROMATE OF POTASH. $K_2Cr_2O_7$=295.—1000 grain-measures contain $\frac{1}{20}$ molecule=14·75 grs.

Use.—This solution is used only for estimating the amount of *ferrous* salt in the preparations of iron, and was introduced for this purpose by Dr. Penny, of Glasgow. The bichrome is easily obtained pure, and the solution is quite permanent.

Procedure.—The iron compound, whatever it be, is dissolved in excess of dilute hydrochloric acid,* and the standard bichrome solution immediately† dropped in until the whole of the ferrous is converted into ferric salt, which is known when a minute drop of the liquid to be tested, placed in contact with a drop of a very dilute solution of *red* prussiate of potash on a white plate, ceases to strike with it a blue colour. The bichrome, it need hardly be said, has no action upon ferric salts. From the amount of bichrome solution consumed, the quantity of ferrous compound is readily calculated from the following data. One molecule of bichrome ($K_2Cr_2O_7$) is known to contain three atoms, and no more, of available oxygen, *i.e.* oxygen which it will give up to other bodies. But since $2\,FeO + O = Fe_2O_3$, we learn by analogy, that two molecules of any ferrous compound *plus* one atom of oxygen will be converted into its corresponding ferric compound, *i.e.* n atoms of oxygen will peroxidize $2n$ molecules of ferrous salt. Therefore, one molecule of bichrome will peroxidize six molecules of any ferrous compound whatever, and the fundamental reaction is typified by the following equation:—

$$6\,FeSO_4 + K_2\,Cr_2O_7 + 7\,H_2\,SO_4 = K_2\,SO_4, Cr_2 3SO_4 + 7\,H_2O + 3\,Fe_2\,3\,SO_4$$

Now the volumetric solution of bichrome contains, for convenience, $\frac{1}{20}$ of a molecule of $K_2Cr_2O_7$, *i.e.* 14·75 grs. ($\frac{295}{20}$), in 1000 grain-measures, the capacity of the burette, which quantity, therefore, will exactly convert $\frac{1}{20}$ of six molecules of ferrous into ferric salt.

Example.—Ferri Oxidum Magneticum is a mixture of ferrous oxide, FeO, with ferric oxide, Fe_2O_3. To determine the precise amount of ferrous oxide,

* The presence of free acid, hydrochloric or sulphuric, is necessary, as otherwise a basic compound of chromium would be precipitated and the oxidizing action interfered with.

† So as to avoid absorption of oxygen from the air.

dissolve a suitable quantity, say 20 grs., in hydrochloric acid, and add the standard solution of bichrome until the iron is all peroxidized. It will be found that 230 grain-measures are required.

The molecular weight of $FeO = 72$, which $\times 6 = 432$, and this $\div 20 = 21{\cdot}6$. Then, 1000 : 230 : : 21·6 : $x = 4{\cdot}96$ grs. of FeO in 20 grs. of magnetic oxide, = 24·84 per cent.

NOTE.—Permanganate of potassium ($KMnO_4$) is also often employed in an analogous way for the estimation of iron by Margueritte's process. 2 $KMnO_4$ or $K_2Mn_2O_8$ yields five atoms of available oxygen and will therefore peroxidize ten molecules of any ferrous compound. The permanganate is added so long as its purple colour is destroyed, and the only case in which this reaction is utilized in the Pharmacopœia is in testing the purity of Potassæ Permanganas.

The bichrome solution is used in determining the proportion of protoxide of iron in the following preparations—

Ferri Arsenias	20 grs.	= 170	grain-measures of vol. sol.
„ Carb. Sacch.	20 „	= 208	„ „ „ „
„ Oxid. Magn.	20 „	= 230	„ „ „ „
„ Phosphas	20 „	= 250	„ „ „ „

VOLUMETRIC SOLUTION OF HYPOSULPHITE OF SODA. $Na_2S_2H_2O_4$ $4\ H_2O = 248$. 1000 grain-measures contain $\frac{1}{10}$ molecule = 24·8 grs.

Uses.—This solution is used in the direct estimation of iodine, and in the indirect estimation of chlorine (chlorimetry) in several chlorinated preparations. Free chlorine cannot be estimated by hyposulphite because, instead of tetrathionate of sodium, sulphate of sodium is formed; but chlorimetry is indirectly affected (Bunsen's method) by first adding an acid to the chlorinated compound to liberate chlorine, then excess of iodide of potassium, whereby for each atom of chlorine present an atom of iodine is disengaged and dissolves in the excess of the potassic iodide, and finally titrating the liberated iodine. Hyposulphite has no action upon iodide of potassium.

Procedure.—The colourless solution of the hyposulphite is added to the solution of iodine until the red colour is completely discharged, or, if starch have been used as indicator, until the blue iodide of starch is decolorized. From the amount of hyposulphite used the quantity of iodine or chlorine is readily calculated. The fundamental reaction is—

$$I_2 + 2\ Na_2S_2H_2O_4 = 2\ NaI + Na_2S_4O_6 + 2\ H_2O.$$

Colourless iodide and tetrathionate of sodium are formed. Therefore, since two molecules of hyposulphite = 2 atoms of iodine, $\frac{1}{10}$ molecule hyposulphite = $\frac{1}{10}$ atom of iodine, *i.e.* 12·7 grains.

Example.—The atomic weight of iodine = 127, and accordingly 12·7 grains of iodine should, if pure, require for complete discoloration exactly 1000 grain-measures of the vol. sol. of hyposulphite.

This solution is used for testing the following substances:—

Calx Chlorata	10 grs.	= 850	grain-measures.
Iodum	12·7 „	= 1000	„ „
Liq. Calc. Chlor.	60. „	= 500	„ „
„ Chlori	4·39 „	= 750	„ „
„ Sodæ Chlor.	70. „	= 500	„ „

VOLUMETRIC SOLUTION OF IODINE. I = 127. 1000 grain-measures contain $\frac{1}{10}$ atom I = 12·7 grs.—Iodide of potassium is employed in the preparation of this solution, simply because it is the best solvent of iodine; it exerts no chemical action upon the substances to be estimated by the iodine.

Use.—This solution is used for the estimation of arsenious and sulphurous acids, and sometimes of sulphuretted hydrogen.

Procedure. — The vol. sol. is dropped from the burette into the liquid to be tested, to which a little starch has previously been added, until free iodine begins to appear in the solution, as evidenced by a permanent blue colour. The solution of sulphurous acid must be considerably diluted before being tested, and the arsenical solutions must all be first rendered alkaline by bicarbonate of sodium.

The fundamental reactions upon which the different estimations depend, are—

I. $SO_2 + I_2 + 2\ H_2O = H_2SO_4 + 2\ HI.$

II. $As_2O_3 + 2\ I_2 + 2\ H_2O = As_2O_5 + 4HI.$

III. $H_2S + I_2 = S + 2\ HI.$

The third reaction is not applied in the Pharmacopœia.

Now, the molecular weight of $SO_2 = 64$, and the molecular weight of $As_2O_3 = 198$; therefore, since 2 atoms of iodine = 1 molecule sulphurous anhydride, $\frac{1}{10}$ I = $\frac{1}{20}$ SO_2 *i.e.*, 3·2 grs., and since 4 atoms of iodine = 1 molecule arsenious anhydride, $\frac{1}{10}$ I = $\frac{1}{40}$ As_2O_3 = 4·95 grains.

In estimating the following substances—

Acidum Arseniosum	4 grs.	= 808	gr.-measures.
„ Sulphurosum	34·7 „	= 1000	„
Liq. Arsenicalis	441·5 „	= 808	„
„ Arsen. Hydr.	441·5 „	= 808	„

(*To be continued*).

NOTES ON ALOIN.

At the meeting of the natural history section of the Imperial Academy of Sciences at Vienna on the 21st. May, Dr. Rochleder described the results of some investigations which have been made in the laboratory under his charge, respecting the principles of aloes.*

Dr. E. von Sommaruga has examined some aloin prepared from socotrine aloes. This aloin is not a glucoside, and differs from nataloin and the aloin from Barbadoes aloes. The melting point of socotrine aloin lies between 118° and 120°C.—*i.e.* the aloin softens at that temperature—while the melting point of aloin from Barbadoes aloes, is given at 150°C. The socotrine aloin is also much less soluble in ether than Barbadoes aloin.

Stenhouse found the composition of Barbadoes aloin could be represented by the formula $C_{17}H_{18}O_7$. The figures obtained by the analysis of socotrine aloin answer to the formula $C_{15}H_{16}O_7$. Nataloin according to Tilden,† has a composition represented by the formula $C_{25}H_{28}O_{11}$, and the acetyl derivative is $C_{25}(C_2H_3O)_6H_{22}O_{11}$, or $C_{37}H_{40}O_{17}$. But the formula $C_{16}H_{18}O_7$ affords nearly the same per centage composition as $C_{25}H_{28}O_{11}$, and the formula $C_{24}H_{26}O_{11}$, or $C_{16}(C_2H_3O)_4H_{14}O_7$ has a per centage composition similar to $C_{37}H_{40}O_{17}$. The figures which Stenhouse obtained with the aloin discovered by Smith in Barbadoes aloes, agree with the formula $C_{17}H_{20}O_7$, equally as well as with $C_{17}H_{18}O_7$. It therefore appears highly probable that the three aloins may be represented as follows:—

Barbadoes aloin	$C_{17}H_{20}O_7$
Natal aloin	$C_{16}H_{18}O_7$
Socotrine aloin	$C_{15}H_{16}O_7$

and that they form the members of a homologous series which is deserving of closer investigation.

When melted with potash, as pointed out by Tilden, nataloin yields paraoxybenzoic acid and β orcin ($C_8H_{10}O_2$). The orcin ($C_7H_8O_2$) which together with parabenzoic acid Hlaziwetz obtained by the melting of socotrine aloes with potash evidently originated with socotrine aloin.

* Proceedings of the kaiserliche Akademie der Wissenschaften in Vienna, 1874, p. 116.

† PHARMACEUTICAL JOURNAL, [3] vol. ii. p. 951.

Barbadoes aloin gives with nitric acid, as has been before stated, chrysammic acid, besides oxalic and picric acids; nataloin, only oxalic and picric acids and no chrysammic acid. The aloin from socotrine aloes gave when treated with nitric acid, oxalic and aloetic acids.

Socotrine aloes treated with nitric acid yields chrysammic acid, besides aloetic and oxalic acids. Chrysammic acid has been thus obtained in an hitherto unknown degree of purity; not as a golden coloured powder, but in golden coloured needles. Their composition was found to answer to the formula of tetranitrodioxyanthrachinone.

The action of bichromate of potash and sulphuric acid upon socotrine aloin gives rise to a substance similar to the purpurin of Krapp.

A description of the method of preparing aloetic and chrysammic acids, their properties, substitution, and decomposition products and combinations, is to form the subject of a special communication.

THE VANILLA.*

The vanilla is remarkable for its climbing habit, which is not common among orchids. There are several species, most of which are natives of the hot and damp regions of South and Central America; the genus is also represented in tropical Asia and Africa. The stems climb to the height of twenty or thirty feet, twining round the trunks of trees, and throwing out a profusion of aërial roots, some of which eventually reach the ground, as is the case with the banyan, while others float in the air. The leaves are thick and fleshy, as also are the greenish-white flowers. The important part of the plant, however, is the pod, which, in some of the species, is an article of commerce, and yields the delicious flavouring which is so well known. Some little uncertainty exists as to which of the species produces the most valuable fruit. It appears, however, that *V. planifolia* and *V. aromatica* are the most important, although *V. guianensis*, *V. palmarum*, and *V. pompona* also yield some of the vanilla of commerce. The pods as imported are narrow and flattened, from five to ten inches long, and of a dark brown colour; they are pulpy within, and contain a great number of very small dark seeds.

A great part of the vanilla of commerce is brought from Mexico and Venezuela, and principally from Vera Cruz, whence, according to Humboldt, the value of the annual export in his time was 40,000 dols. The cultivation is mainly carried on at Misantla, twenty-four leagues northwest of Vera Cruz, the inhabitants of which are the only people in Venezuela who cultivate the plant. The growth is, indeed, extremely easy, as the ground requires no tilling: slips of the vanilla plant are set at the foot of a tree on the approach of the rainy season, and soon begin to spread up the trunk. The plantations are cleared once a year from weeds and undergrowth, and in the third year the plants bear fruit.

Five varieties are recognized by the growers. One, the vanille de cochon, is so called from emitting an offensive smell whilst drying. The harvest begins about December, when the fruit becomes yellowish-green. There are two ways of preparing it for the market. In one method the fruit is allowed to dry until the pod loses its green colour. Straw mats covered with woollen blankets are spread on the ground, and when these are warmed through the fruits are spread on them and exposed to the sun. After a time they are wrapped in blankets, and placed in boxes covered with cloths, after which they are again exposed. In about twelve hours the fruits should become of a coffee colour, but if they do not the process is repeated. After about two months' daily exposure they are tied up in bundles of fifty, and packed in tin boxes. Five qualities of vanilla pods are known: the best is the *primiera*, the pods of which are twenty-four centimetres long, and proportionately thick. The second quality is called *chica prima*, the pods of which are shorter, and two count as one; the third, *sacate*, and the fourth, *resacate*, are still smaller, four of the latter being reckoned for one; they are gathered before they are ripe. The fifth and poorest quality is called *basura;* the fruit is very small, spotted, and much cut or broken about.

*From the *Gardeners' Chronicle* for May 23rd, 1874.

The following is another method of preparing vanilla for the market: About 12,000 of the pods are strung together by their lower end, as near as possible to the footstalk; "the whole are plunged for an instant into boiling water to blanch them; they are then hung up in the open air and exposed to the sun for a few hours. By some they are wrapped in woollen cloths to sweat. Next day they are lightly smeared with oil by means of a feather or the fingers, and are surrounded with oiled cotton to prevent the valves from opening. As they become dry, on inverting their upper end they discharge a viscid liquor from it, and they are pressed several times with oiled fingers to promote its flow. The dried pods, like the berries of pepper, change colour under the drying operation, grow brown, wrinkled, soft, and shrink to one-fourth of their original size. In this state they are touched a second time with oil, but very sparingly, because with too much oil they would lose some of their delicious perfume."

It appears somewhat remarkable that the cultivation of vanilla in the West Indies has not been largely undertaken, as it would be attended with but little difficulty, and would be a source of much profit to the inhabitants. But even in Caraccas and Guiana, where the plant grows profusely in a wild state, it is almost entirely neglected. In the Isle of Bourbon, however, it has been cultivated with considerable success, and seventeen and a half tons were exported from Réunion in 1871. At Liége it is grown on a small scale to the value of 600 francs per annum; and a plant cultivated at Paris in 1840 attained the height of three yards, and yielded 117 pods, which ripened in twelve months. In England it has been in cultivation since 1759; fine examples may be seen in the tropical and economic houses at Kew. Mr. Ewing and Mr. E. Bennett grew the vanilla with considerable success at Osberton; the latter gathered no less than 300 ripe pods off a single plant in one season. He considers a temperature of from 50° to 70° to be most suitable for it. He found it necessary to effect fertilization by artificial means, the stigma being prevented from receiving the pollen of its own flower by the interposition of an organ called the retinaculum.

As the English-grown pods are very highly flavoured, it is possible that it might be practicable to grow it for economic purposes. The annual import of vanilla amounts to about five or six cwt.; its price varies very greatly, being sometimes as high as 125*s.* per pound, and at other times as low as 26*s.*

The chief use of the vanilla is in flavouring perfumery and confectionery, and especially chocolate. One pod is sufficient to flavour a pound and a half of chocolate, being ground with sugar for that purpose. The fragrance is said to act upon the system as an aromatic stimulant, exhilarating the mind, and increasing the energy of the animal system. It is occasionally employed on the Continent in cases of hysteria; and is used by the Spanish physicians in America as an antidote to poison and to the bite of venomous animals, as well as in other cases. A liquid used in Peru, where it is known as *Baume de vanille*, exudes from the open pods at perfect maturity. The fruits in time become covered with an efflorescence of fine needle-like crystals, which possess properties similar to those of benzoic acid; when viewed through a microscope with polarized light they are very beautiful objects.

De Menonville, who travelled to Guaxaca in 1777, thus describes his discovery of vanilla in that district. After various hindrances and disappointments he says:—"At length an Indian, with a hoe in his hand, made his appearance. 'Brother,' said I, holding out a dollar, 'show me some vanilla and this is yours.' He coolly bade me follow him, and advancing a few steps through the underwood into a thicket, in which were a number of trees, he immediately climbed up one, threw down to me two pods of vanilla perfectly ripe, and pointed out to me a branch on which several others were hanging yet green, together with two faded flowers. The form of the leaves, the fruit, the peculiar smell of the plant—everything convinced me it was the real vanilla in everything corresponding with such as I had seen at Vera Cruz. All the trees of this little copse were covered with it. I saw a quantity of green fruit, but collected no more than six specimens of these, and four large pods which were ripe. I caused the Indian afterwards to part from the root some of the scions which had sprung up. These I tied well together, wrapping up the whole in the leaves of an Arum, which at their base are 3 feet wide. After thus packing a faggot, which weighed upwards of 30 lb., I placed it in my large sack, which I fastened on my horse. I was so well satisfied with my Indian, that besides what I promised him, I give him two reals in addition. For his part, unwillling to be outdone in generosity, he ran to his hut, and brought me three other pods of vanilla."

The Chica Vanilla of Panama is yielded by another Orchid, a species of Sobralia. The expressed juice of *V. claviculata*, a native of mountainous woods in the West Indies, is applied to recent wounds, and is hence called by the French in S. Domingo *Liane à blessures.* There is a species known as *zizpic* in Yucatan, which is a great ornament of the *cenotes* or subterranean water caverns of the country. These singular caverns are sometimes entirely subterranean, and are then of course without vegetation; frequently, however, they are more or less open at the top, when they are often of surpassing beauty on account of the luxuriant development of vegetable life which they contain. To these *cenotes* the few ferns of Yucatan are almost confined, and it is here that this vanilla attains perfection. The pods are occasionally taken to market at Valladolid, where they may be bought at an almost nominal price.

ADMIXTURE OF JAPAN WAX WITH BEES-WAX

BY C. MENE.

For some years past Japan wax has been offered in the ordinary French markets, where it is quoted at a price less than half that of bees-wax. The author, finding that it was used largely in the sophistication of bees-wax, thought it would be useful to seek a short and easy method of detecting the fraud. He therefore made numerous experiments as to the densities and melting and solidifying points of these substances, and mixtures of them in different proportions.* The results, from which the following notes are taken, were recently communicated to the French Academy.*

	Density.	Melting point.	Solidifying point.
Pure Yellow Japan Wax	1·00200	52-54° C.	45-46° C.
Bees-wax	9·96931	64-65	63-64
Mixtures :—			
50 per cent. Japan Wax / 50 „ Bees-wax .	0·93518	64-65	61-62
60 „ Japan Wax / 40 „ Bees-wax .	0·92785	64-65	61-62
65 „ Japan Wax / 35 „ Bees-wax .	0·90730	64-65	61-62
70 „ Japan Wax / 30 „ Bees-wax .	0·90452	63-64	61-62
75 „ Japan Wax / 25 „ Bees-wax .	0·90164	63-64	62-63
80 „ Japan Wax / 20 „ Bees-wax .	0·88703	63-64	62-63
90 „ Japan Wax / 10 „ Bees-wax .	0·85100	63-64	62-63

The densities of these substances were taken in alcohol, and their relation to the density of water calculated. As will be noticed, the density alone furnishes any help in detecting the fraud, the density of the mixture being always less than that of Japan wax or bees-wax. The author, therefore, thinks that the points of melting and solidification are of no service whatever.

It will be remembered, however, that Dr. Roucher, in an article on the employment of vegetable wax in pharmacy,* stated that he had found that Japan wax has two distinct melting points. As to the highest, he agrees with M. Mène in fixing it at 54° C.; this he states to be the melting point when the heat is applied gradually. But when Japan wax was rapidly raised to a temperature sufficiently above its melting point and allowed to cool, it afterwards melted at 42° C., or a temperature twelve degrees lower. As bees-wax presents no similar phenomenon, Dr. Roucher suggested that this would be an available test between the two substances. It would be interesting to know in what way mixtures of the two substances comport themselves under similar conditions.

* *Comptes Rendus*, vol. lxxxviii., p. 1544.

SYRUP OF HYPOPHOSPHITE OF IRON.

BY P. CARLES.

Syrup of hypophosphite of iron having for some time past been frequently prescribed by the physicians of Bordeaux, the author took occasion to criticize,—at a recent meeting of the Society of Pharmacy in that city,† the previously existing formulæ for its preparation.

He alluded principally to two formulæ, as being the more generally known, those of Wood and Hardy.

Wood's formula is represented by the author as consisting in the mixture of two solutions—one of sulphate of iron, acidulated with phosphoric acid, with another of hypophosphite of lime.‡ Sulphate of lime is formed, which is precipitated, whilst the acid hypophosphite of iron remains in solution, and is afterwards mixed with simple syrup. M. Carles says of this formula, that it is defective, in that (1) it gives an acid solution, in consequence of the addition of the phosphoric acid, which changes the nature of the desired product; (2) that it furnishes a syrup which is too dilute and difficult to preserve; (3) that the proportions of the ingredients do not correspond with the equivalents, 85 for the hypophosphite and 139 for the ferrous sulphate, required for double decomposition to take place exactly.

Hardy's formula consists in preparing hypophosphorous acid by the aid of hypophosphite of baryta and q. s. sulphuric acid, removing sulphate of baryta by filtration, and producing the hypophosphite of iron by boiling metallic iron in the dilute acid. This formula is criticized by the author on the ground that hypophosphite of baryta is a salt rarely met with in pharmacy, and, what is of more importance, is a poisonous salt; so that if the operation be conducted by a person only little accustomed to chemical reactions, a portion, in consequence of its solubility, may remain undecomposed in the liquor, and give rise eventually to a poisonous medicament. Besides, the process is tedious and minute, and requires special apparatus.

Another method which has been suggested, is to prepare the solution of hypophosphite of iron intended for the syrup, by double decomposition between oxalate of iron, which is now to be met with in most French pharmacies, and hypophosphite of lime. M. Carles finds, however, that in practice this method is very defective.

Commercial neutral oxalate of iron requires for its solution a large quantity of liquid, and the same inconvenience, though in less degree, occurs with hypophosphite of lime; so that the precipitation of the oxalate of lime is

* PHARM. JOURN. [3], vol. iii., p. 122.

† *Bulletin des Travaux de la Societe de Pharmacie de Bordeaux*, vol. xiv., p. 102.

‡ This does not quite correctly describe Wood's process, as may be seen by reference to the original paper in this Journal (second series, vol. ix. p. 461), where it is recommended to "rub the hypophosphite to fine powder, and pour on it the solution of sulphate of iron."

very slow, and the solutions are too dilute to be converted into syrup.

From a consideration of these facts, the author sought for a simple and rapid method, but one where the quality of the product would not be sacrificed to celerity. At first he thought to prepare the hypophosphite of iron by means of ferrous sulphate and hypophosphite of soda. The great solubility of these salts allowed of their being brought into contact in a very small volume of liquid. The addition of alcohol to the mixture separates the sulphate of soda, so that after filtration and evaporation of the alcohol, there remains a solution of hypophosphite of iron, which only requires to be mixed with very concentrated sugar syrup, or to be itself converted into syrup by the addition of suitable quantities of boiled water and sugar. Unfortunately alcohol only slowly and incompletely determines the precipitation of the sulphate of soda, and the filtration too is slow, so that in the interval the hypophosphite becomes partially insoluble and peroxidized.

M. Carles has finally adopted the following process as the best:—

Ferrous sulphate (crystals)	15·00
Hypophosphite of soda (crystals)	9·14
Distilled water (boiled)	350·00
Powdered sugar	660·00

The ferrous sulphate is pulverized and dissolved separately in about 20 grams of the water, and the hypophosphite in the remainder. The two solutions are mixed, and agitated violently. After a quarter of an hour the magma is thrown upon a fine cloth, pressed, and if necessary filtered through paper of open texture. A sufficiency of boiled distilled water is then added to make up the quantity of 360 grams of liquid, in which the sugar is dissolved by the aid of a gentle heat. The keeping of the syrup in partially filled bottles should be avoided as much as possible.

Each spoonful (25 grams) of the above syrup will contain 0·25 centigrams of hypophosphite. By mixing the syrup with an equal quantity of syrup of orange flowers, a medicine of much more agreeable flavour will be obtained. In this case each spoonful will contain 0·125 centigrams of hypophosphite of iron.

REPORT FROM THE SELECT COMMITTEE ON ADULTERATION OF FOOD ACT (1872).

The Select Committee appointed to inquire into the operation of the Adulteration of Food Act, 1872, have considered the matters referred to them, and have agreed to the following report:—

Your Committee having held 14 meetings, and examined 57 witnesses, have arrived at the unanimous conclusion that the Act has done much good. It has, at the same time, inflicted considerable injury, and imposed heavy and undeserved penalties upon some respectable tradesmen. This appears to have been owing mainly to the want of a clear understanding as to what *does* and what *does not* constitute adulteration; and in some cases to the conflicting decisions and inexperience of the analysts. Your Committee, however, are of opinion that the Act itself is defective, and needs amendment.

The adoption of the Act has been by no means general, and in many cases where it is applied and officers have been appointed, its operation has been of the most restricted character. Even where a competent analyst has been established, if the local authority does not associate a special inspector with him, or does not insist upon the police or other recognized officials performing the duties of inspectors, the Act remains a dead letter. It appears that only in 26 boroughs and 34 counties have appointments been made, while the number of boroughs under the Act is 171, and of counties, 54. In the City of London the Commissioners of Sewers, and in the rest of the metropolis all the vestries or district boards under the Metropolis Local Management Act, have appointed analysts.

From a return of the convictions in the year 1873, as received by the Home Office, it will be seen that the number of proceedings outside the metropolis and a few large towns has been singularly small. The amount of good resulting from the Act must not, however, be judged by the number of the prosecutions and convictions. The deterrent effects are undoubtedly great, and the opinion of the promoters has been substantiated, that the most beneficial effects of the Act would be to prevent adulteration, rather than to punish it.

Tea.—It appears that, since the Report of 1856, certain grossly prepared teas have been imported from China, some being largely mixed with exhausted leaves and ferruginous sand, and others much too highly faced or coloured; the ingredients used for colouring being chiefly Prussian blue or indigo, powdered gypsum and turmeric; but the total amount of such teas has been small, and is kept in check mainly by the low price of pure teas. The import of green teas has recently fallen considerably, in consequence, it is stated, of the operations of the Act.

Facing tea after the duty is paid was, prior to the Act of 1872, practised to a small extent in this country; but whether in China or at home, the evidence is conclusive that in colouring tea no deleterious matter is used to such an extent as to be absolutely injurious to health; at the same time facing may be employed to conceal tea of a bad quality. Your Committee have reason to believe that very little adulteration of tea is practised in this country.

They would further observe that defacing tea, or removing artificial colour, seems now much more common, but this process does not appear to extract the ingredients which form the base of the colouring matter; it simply removes the colour, leaving all the other materials on the tea.

It is proved that the bright green teas of China are always faced, and that the natural green teas of Japan, India, etc., are frequently of a colour hardly distinguishable from some qualities of black tea. While condemning the practice of highly facing tea, your Committee cannot recommend that fairly faced green tea should be condemned as an adulterated article.

Suggestions have been made that a certain per-centage should be allowed for colouring matters and other impurities in tea. But your Committee consider that the limitation to a very small per-centage of foreign matter would exclude from the country some wholesome low-priced teas, which are largely consumed by the poor, and if a less stringent limit were adopted, it might have the effect of increasing the amount of facing laid upon the better descriptions of green teas.

The Act has borne with considerable hardship upon the retail grocers, among others, from the following causes:—The evidence and samples being, in the first instance, entirely in the hands of the prosecution; the defendant being incapacitated as a witness; the sole employment of analysts, to the exclusion of practical judges of the article; the differences among analysts, and the magisterial decisions thereon; and the recent judgment of the Court of Queen's Bench, that under this Act the faced tea known as green tea is adulterated; but more especially that the alleged adulteration has taken place before the tea reached the retailer, and that he is not responsible for the frauds and tricks of the Chinese manufacturer.

It has been repeatedly suggested to your Committee that an examination of tea, for the purpose of detecting impurities, should be undertaken on landing by the Customs; and that all tea found to be seriously adulterated should not be admitted for home consumption.

The Chairman of the Customs admitted that such an inspection of tea in bond could be undertaken by the Custom House officers, and that the great bulk of the tea would require but a brief examination by good practical officials, while suspected samples could be analysed at the laboratory at Somerset House.

Your Committee recommend that this examination should be made, as they believe it would practically stop the sale in this country of tea adulterated abroad, and relieve the retail dealer from the hardship which now arises from his being held answerable for certain manipulations of which he may be wholly ignorant.

Milk.—The evidence before your Committee points to the fact that, previous to the passing of the Act of 1872, milk was generally adulterated with water. It has since greatly improved in quality wherever the Act has been enforced, but the good results in improving the milk supply have not been attained without some serious cases of injury and injustice to milk-sellers.

Too high and rigid a standard has been fixed by some analysts, and no sufficient allowances have been made for the natural variations in milk. Ten per cent. of milk solids may be more difficult to obtain under certain unfavourable conditions than twelve or fourteen under a more generous diet, a warmer atmosphere, and more confortable lodging. Not only does the quality of milk vary with the food, the breed of cattle, the time of year, and treatment of the animals, but the milk of one cow of the same breed will differ greatly from that of another, managed under a precisely similar system; and further, the first and last pint of milk which a cow gives at the same milking will present all the difference between an extremely poor, and an exceedingly rich milk. Allowances should therefore be made for these natural variations, which some purely scientific chemists seem to have occasionally overlooked.

It has been argued that, notwithstanding all these discrepancies, a certain per-centage of solids might be agreed upon below which no milk should be considered pure. If a low standard were fixed, there would be a great inducement for the vendors of really rich milk to abstract a portion of the cream without reducing the milk below the recognized standard, and, on the other hand, it might offer a premium upon the production of a naturally poor class of milk.

Your Committee are decidedly of opinion that the fraudulent abstraction of cream should be punishable; at the same time they consider the sale of skim milk should be encouraged, as it is certainly a nutritious and valuable article of food; but your Committee are unanimous that the sale of *skim* milk for *new* should decidedly be regarded as a punishable offence.

Butter.—Butter is often imperfectly made in the United Kingdom, and sometimes contains too much water, and now and then an unfair proportion of salt; beyond this, it does not appear that adulteration is much practised in this country. Certain foreign butters are mixed with lard and other fats, and there is reason to believe that salt and water, after the butter comes from the farmer, are added in some manufactories abroad. Attempts are being made in France and elsewhere to manufacture artificial butter, chiefly from the fat of animals; if these articles are composed of wholesome materials, and not sold as butter, your Committee see no reason to forbid their sale. The slight colouring matter occasionally added to butter, cheese, etc., should not, in the opinion of your Committee, be regarded as an adulteration.

Bread.—Bread, on the whole, appears to be fairly pure. Potatoes are used to help fermentation, and rice flour is employed in dusting the loaves. No doubt the chief adulteration is alum, and evidcnce was adduced showing the great difficulty which the best chemists experience in discovering minute quantities of alum in bread.

Mixtures.—Your Committee have had under their consideration the sale of mixed articles of food and condiments; amongst them great prominence has been given to mustard and cocoa. The evidence tends to show that these articles have been sold pure, as well as mixed with other ingredients, to suit the requirements of consumers. And it has also been demonstrated, to the satisfaction of your Committee, that the compounds are frequently made quite as much to suit the public taste as to increase the profit of the manufacturers, inasmuch as by using a lower quality of mustard-seed or cocoa-bean, a pure article may be made at a lower price than some of the mixtures. For this reason the statement of the proportion of each ingredient used could not be any real protection to the consumer, and should not be required. It is also due to the manufacturer to record that mixed mustard and prepared cocoa are, and have long been, manufactured at the Deptford Yard, for the supply of the navy.

Your Committee, therefore, come to the conclusion that the sale of such mixtures or compounds is allowable, and, indeed, needful, to meet the public requirements, provided the fact of their being mixtures is plainly indicated to the purchaser by a legible label or notice, conspicuously attached to the outside of each package in which, or vessel from which such mixture is sold. A verbal declaration at the time of sale is impracticable, and if practicable would be unnecessary when a proper label is used.

Corn Flour.—The attention of your Committee has been called to the article known as corn flour, in reference to which important evidence as to its purity and its useful dietetic qualities has been given by some eminent medical and chemical authorities, which, however, is denied by one witness. Your Committee are fully convinced that the manufacture is quite legitimate, and that like arrowroot, sago, and other starch foods, corn flour is perfectly wholesome, but that it should not in any case be given to infants without a considerable admixture of milk.

Wines, Spirits, and Beer.—The adulteration of wines, spirits, and beer, have not been extensively examined under the Act of 1872. The Licensing Act, which was passed in the same year, contained special clauses against the adulteration of these articles. The evidence before your Committee is of a negative character, and it may be that alcoholic drinks have slipped through between the two Acts. The adulteration clauses in the Licensing Act are sought to be repealed by a bill that has just passed the House of Commons, and there appears to be no reason to doubt that if this Act is amended as your Committee suggest, it will contain ample powers for detecting the adulteration in the drink as well as the food of the people. Witnesses have stated that spirits are largely diluted with water, but are rarely adulterated with sulphuric acid; that almost all wines are more or less "fortified" for the English market; and that water is often added by the publican to beer and porter (perhaps with an addition of salt or sugar), but few of those villainous compounds with which malt liquors were formerly much adulterated have been recently discovered by any analysis. There was a singularly unanimous expression of opinion from many scientific witnesses as to the baneful and maddening effects produced by the consumption of very new and roughly-distilled spirits.

Several witnesses have complained to your Committee of the manner in which the cases under this Act have been tried before justices. They state that in some instances the magistrates, considering the prosecution to be a criminal one, would not allow the defendant to be examined. Your Committee believe that, in all cases, this privilege should be accorded to the accused and his wife. Your Committee also think that when a retail dealer, charged with adulterating an article, shall produce evidence that he bought the article under guarantee from a wholesale dealer, and that he sold the article in the same state and condition as he received it from such wholesale dealer, it shall be lawful for the magistrate, upon the retail dealer giving security for costs, to summon the wholesale dealer as well as the retailer. In some cases, magistrates have declined to allow any other analysis than that of the analyst appointed to act for the district to be taken as evidence. Your Committee think that evidence from well-established analysts should be allowed to be produced for the defence; and they suggest that when cases of dispute arise between the chemical authorities, there should be some court of appeal to settle the disputed points. It has been suggested that such an authority might be easily established at the laboratory of

Somerset House; and the official witness from that department gave your Committee to understand that, with a little enlargement and assistance, the existing laboratory and staff could undertake these important duties. In the absence of further information as to any better appeal, your Committee suggest that where the analysis of the chemist of the local authority is challenged, the sample which is the matter of dispute shall be analysed at the laboratory of Somerset House, and the decision arrived at there be regarded as final.

It was stated to your Committee that some justices would not accept the analysis of the chemist of the local authority without his presence in court; others insisted on his signature to his analysis being duly witnessed, and in all cases it appears that the inspector is bound himself to deliver the sample of the goods to the analyst. This, besides taking the inspector for days from his legitimate duties, entails considerable expense upon the local authority, in the case where the analyst resides outside the district or where one gentleman holds several appointments. Your Committee consider that if the sample is duly secured, and properly sealed, it may be sent by post, or by other safe means; and they are of opinion that the analysis of the chemist of the local authority should be received in evidence without his presence being necessary, unless the defendant should demand the personal attendance of such analyst. There does not seem to be much necessity for attestation of the analyst's signature, nor is it apparently required by existing Acts, but in any case your Committee consider that the practice in this particular should be everywhere similar, and that proper forms for the analysis of different articles should be issued by some central authority, so as to secure greater uniformity and more detail in these documents in all courts of justice.

Many witnesses have declared that the failures and hardships in carrying out the Act have been chiefly due to the incompetence and inexperience of the analysts. Your Committee, whilst refraining from endorsing this wholesale condemnation, admit that some of these gentlemen appear to have evinced more zeal than discretion in carrying out their novel and difficult duties. In some cases, indeed, a decided want of chemical knowledge has been proved, but no more than was to be expected from the sudden call made for the services of adepts in a branch of chemistry which had not previously been very highly valued. Witnesses testified their belief that few really competent analysts were at present to be found in this country, and one eminent chemist stated that he did not think more than "a dozen such men existed;" but, as chemical analysis will now be better taught and better understood, there seems to be no reason to doubt that in a few years there will be an abundant supply of reliable scientific analysts. In the meantime, it seems to your Committee that small districts should be as much as possible consolidated; that, as a rule, the boroughs in a county should be united with the county for the purposes of appointing one analyst for the entire district, and that the only way of securing the services of really efficient analysts is to offer them a fair remuneration, which can hardly be done without the union of several local authorities in one appointment.

To the Local Government Board has been confided the power of revoking or confirming the appointments of the analysts; but without any recognized authority to guide them (beyond the long list of testimonials which seem always forthcoming), the Board have not the means of performing satisfactorily the task imposed upon them. Your Committee think some practical test might reasonably be required from the analysts, to prove their competency to perform the duties of their office.

Evidence has been offered to your Committee that the requisites for a thorough examination of the knowledge and skill of the analyst exist at the School of Chemistry at South Kensington; and they suggest that the Local Government Board should have the option of calling upon the analyst for a certificate of having there passed such an examination.

Complaints have been made by the metropolitan vestries that the fines inflicted under the Act are paid to the General Police Fund. Your Committee think that the Act of 1860 intended that the fines should be paid to the vestries; and they are of opinion that it is only reasonable the fines should go the local authority which has had the trouble and expense of enforcing the Act.

Your Committee consider that inspectors, when traders refuse to sell them articles which are exposed for sale, should be empowered to take samples of goods they suspect to be adulterated, upon tendering payment of the full value of the article. That in all cases the inspector should leave with the trader a duplicate sample of the goods he intends to have analysed, properly securing and sealing the same in the presence of the vendor; and that in no case shall more than one month elapse before the result of the investigation is made known to the trader.

Your Committee suggests that the two Acts to which this inquiry refers, viz., the Adulteration Acts of 1860 and 1872 (23 and 24 Vict. c. 84, and 35 and 36 Vict. c. 74), should be repealed, and another Act, consolidating and amending these statutes, substituted for them. That in the new Act, besides the changes already recommended, it should be provided that the fraudulent abstraction of important properties of any commodity, should be a punishable offence, but that a distinction should be drawn between this and the fraudulent or noxious addition of ingredients, which, more strictly speaking, constitutes adulteration; and that Clause 9 of the Act of 1872 should be so far modified as not to make it incumbent on the analyst to give a certificate, except when he finds the articles submitted to him to be adulterated or debased. They further recommend that the Act should be made compulsory.

In conclusion, your Committee believe it will afford some consolation to the public to know that in the matter of adulteration they are *cheated* rather than *poisoned*. Witnesses of the highest standing concur in stating that, in the numerous articles of food and drink which they have analysed, they have found scarcely anything absolutely injurious to health; and that if deleterious substances are occasionally employed for the purposes of adulteration, they are used in such minute quantities as to be comparatively harmless. Your Committee believe that it is the intention of Parliament that consumers should be protected from frauds, and that they should be enabled to procure the articles they ask for and require. But your Committee do not consider that Parliament desires needlessly to hamper or fetter trade, still less to interfere between the buyer and seller with the view of regulating prices, or attempting to assist the consumer in ascertaining the real money value of any marketable commodity.

REPORT FROM THE SELECT COMMITTEE ON EXPLOSIVE SUBSTANCES.

The Select Committee appointed to inquire into the law relating to the making, keeping, carriage, and importation of gunpowder, nitro-glycerine, ammunition, fireworks, and all substances of an explosive nature, and to consider the best means of making adequate provision for the safety of the public, and of the persons employed in such making, keeping, carriage, and importation, with a due regard to the necessities of the trade, have issued their report, of which the following is an abstract.

The explosive substances to which the Committee have directed their attention, are classified as follows:—

(1.) *Gunpowder;* viz., any preparation formed by the mechanical mixture of a nitrate with any form of carbon, or with any carbonaceous substance not possessed of explosive properties, whether sulphur be or be not added to such preparation, and whether such preparation be or be not mechanically mixed with any other non-explosive substance. This class comprises such explosives as gunpowder (ordinarily so called), pyrolithe, pudrolithe, poudre-saxifragine. Any preparation of this class, if mechanically mixed with any nitro-explosive or chlorate-explosive is included in the nitro class or chlorate class respectively, and not in this class.

(2.) *Nitro-explosive class;* viz., any chemical compound possessed of explosive properties, or capable of combining with metals to form an explosive compound which is produced by the chemical action of nitric acid (whether mixed or not with sulphuric acid), or of a nitrate mixed with sulphuric acid upon any carbonaceous substance, whether such compound is mechanically mixed with other substances or not.

This class consists of two divisions. The first comprises such explosives as nitro-glycerine (ordinarily so called), dynamite, lithofracteur, dualine, gly-oxiline, nitrate of methyl, and any chemical compound, or mechanically mixed preparation, which consists either wholly or partly of nitro-glycerine, or of some other liquid nitro-explosive.

The second division comprises such explosives as gun-cotton (ordinarily so called), gun-paper, xyloidine, gun sawdust, nitrated gun-cotton, cotton gunpowder, Schultze's powder, nitro-mannite, picrates, picric powder. Where any explosive of this class consists partly of a nitro-explosive and partly of a chlorate-explosive, it is to belong to the chlorate-explosive class.

(3.) *Chlorate-explosive class;* viz., all preparations containing a chlorate mechanically mixed with any form of carbon or any carbonaceous substance, either with or without the addition of a nitrate, or a sulphuret, or sulphur.

This class consists of two divisions. The first comprises such explosives as Horsley's blasting powder, Brain's blasting powder, and any chlorate preparation which consists partly of nitro-glycerine or of any liquid nitro-explosive.

The second division comprises such explosives as Horsley's original blasting powder, Erhardt's powder, German gunpowder, Reveley's powder, Hochstadter's blasting charges, Reichen's blasting charges, teutonite, chlorated gun-cotton.

(4.) *Fulminate-explosives;* viz., any chemical compound or mechanical mixture, which, from its great susceptibility to detonation, is suitable for employment in percussion caps or any other appliances for developing detonation, or which, from its extreme sensibility to explosion, and from its great instability (that is to say, readiness to undergo decomposition from very slight exciting causes), is especially dangerous.

This class consists of two divisions. The first division comprises such compounds as the fulminates of silver and of mercury, and preparations of these substances, such as are used in percussion caps; and any preparation consisting of a mixture of a chlorate with phosphorus, or certain descriptions of phosphorus compounds, with or without the addition of carbonaceous matter, and any preparation consisting of a mixture of a chlorate with sulphur, or with a sulphuret, with or without carbonaceous matter.

The second division comprises such substances as the chloride and the iodide of nitrogen, fulminating gold and silver, diazobenzol, and the nitrate of diazobenzol.

(5.) *Ammunition.*—This class includes any explosive of any of the foregoing classes, when enclosed in any case or contrivance, so as to form a cartridge for small arms, or for a weapon other than cannon; or to form any fuze for blasting or for shells; or to form any tube for firing guns; or to form a percussion cap, a detonator, or any contrivance other than the following: a cartridge or charge for cannon or blasting, a shell, a torpedo, or a manufactured firework.

This class consists of two divisions:—The first division comprises—Safety cartridges for small arms, safety blasting fuzes, percussion caps, railway fog signals, safety fuzes for shells.

The second division comprises—Non-safety cartridges for small arms, detonators, non-safety fuzes for blasting, non-safety fuzes for shells, war rockets, tubes for firing guns.

(6.) *Fireworks.*—This class consists of two divisions. The first comprises firework composition, which is any chemical compound or mechanically mixed preparation which is of a combustible or inflammable nature, and is used for the purpose of making manufactured fireworks, and which is not included in the former classes of explosives; and also any coloured fire composition.

The second division comprises any manufactured firework, which includes every explosive of the four first of the foregoing classes, and any firework composition, when such explosive or composition is enclosed in any case or contrivance, or is otherwise manufactured, so as to form a squib, cracker, or other article adapted to the production of pyrotechnic effects or pyrotechnic signals.

The law relating to the foregoing explosives is at present contained in five public Acts, viz.:—The Gunpowder Act, 1860, 23 & 24 Vict. c. 139; Gunpowder Amendment Act, 1861, 24 & 25 Vict. c. 130; Gunpowder Amendment Act, 1862, 25 & 26 Vict. c. 98; the Carriage of Dangerous Goods Act, 1866, 29 & 30 Vict. c. 69; Nitro-Glycerine Act, 1869, 32 and 33 Vict. c. 113. There are also a number of local and special Acts containing provisions upon this subject, of which the more important are the 14 & 16 Vict. c. 67, and the 28 & 29 Vict. c. 278, both relating to the storage of explosives in Liverpool and on the River Mersey.

In the opinion of the Committee, the Acts above-named do not make adequate provision for the manufacture, storage, and transport of many of the explosives to which their attention has been directed; nor for the safety of the public, or of the persons employed in dealing with those explosives, while some of them impose in some respects unnecessary restrictions, and consequently further legislation is required.

The Committee find that the stores of gunpowder may practically be divided into three classes:—(1) Store magazines, belonging to gunpowder manufacturers and merchants; (2) Consumers' magazines, for mine and other purposes; (3) Retail stores.

It appears, with regard to the situation of many of the large store magazines, that the safety of the public is not sufficiently provided for by adequate isolation of the magazines with reference to the quantities which they contain; and that the precautions taken by the store keepers of these magazines in the very large majority of cases, are not of the character which are shown to be necessary to insure safety, and which are adopted in Government magazines. Also, that the present law with regard to consumers' magazines is, in many instances, inconvenient and impracticable, while the evidence before the Committee tended to show that very great carelessness prevails in the management of these stores.

With regard to the retail stores, the Committee find that, except in regard to the amount which may be kept, they are wholly unregulated by the Acts; and as this trade may be carried on without a licence or registration, there is really no supervision with regard to the place or mode of storage, or as to the persons by whom such retail trade may be carried on.

The evidence of many of the witnesses goes to show that no adequate provision is made for the public safety as to the proper package or modes of conveyance for explosives when transported from one place to another, or for forbidding the transport, the loading and unloading of dangerously large quantities, through cities and populous places. The present general law does not in any way regulate the importation or exportation of gunpowder.

With regard to the manufacture of nitro-explosives, the Committee find that, excepting the Nitro-glycerine Act, (32 & 33 Vict. c. 113), which forbids the manufacture of nitro-glycerine preparations, except by licence from the

Secretary of State, there is no adequate legal provision for regulating the manufacture, storage, transport, importation, or shipment of explosives of this class. But the law relating to the keeping of some preparations of nitro-glycerine is unnecessarily restrictive as compared with the legislation relating to other explosives, and a similar remark applies to the carriage, importation, and exportation of such preparations of nitro-glycerine. The law relating to the chlorate and fulminate class appears to be insufficient to the public safety.

With regard to the ammunition and firework classes, the Committee find that, while the law fails to provide adequately for the safety of the public, and the persons employed in those trades, it is in some respects unduly restrictive and inconvenient to the persons engaged in them.

The Committee, therefore, consider that the law relating to the making, keeping, carriage, and importation of gunpowder, nitro-glycerine, ammunition, fireworks, and all substances of an explosive nature, does not make adequate provision for the safety of the public, or of the persons employed in such making, keeping, carriage, and importation, and that further legislation is urgently required with a due regard to the necessities of the trade.

A "Summary of Suggestions" submitted by Major Majendie, with modifications made in consequence of other evidence, was adopted by the Committee as the basis of their recommendations for further legislation, which include the following points—

A new Act to amend and consolidate the Acts regulating the manufacture, keeping, selling, carrying, and importing of explosive substances according to the foregoing classification, the manufacture of gunpowder being made the subject of separate provisions, and power being given to Her Majesty in Council to extend the Act to any explosive not specifically named or defined in the same. Except such operations as the filling of small-arm cartridges, the preparing of blasting cartridges (which should be permitted to be carried on without a license, but under certain precautions to secure safety), the manufacture of explosives and the operations connected therewith to be carried on only under a "common" or "special" licence, without one of which licences also,

No person to keep any explosive above a certain limit, except a carrier carrying in accordance with the Act, and not keeping the same beyond the time actually necessary for his business. No person to sell or deal in explosives unless he hold a license to manufacture, keep, or import such explosives, and no explosives to be imported without a "special" licence.

"Common" licences, for a term not exceeding ten years without renewal, to be obtained as a matter of course, on application to the licensing authority, unless the person or premises be disqualified. In the case of manufacturers, to be granted for the manufacture of fireworks on a small scale.

In the case of storage "common" licences to be of two sorts :—(*a*) "Common house" licences to meet the case of the ordinary retailer, and authorizing the storage up to 300 lbs. of gunpowder, or 1,500 lbs. if in cartridges, and proportionate amounts of fireworks. (*b*) "Common magazines" licence to meet the case of the mine owner, or person requiring to store more considerable quantities for industrial operations, authorizing the storage up to two tons of gunpowder or one ton of gun-cotton or dynamite, or five times the amount of gunpowder in small-arm cartridges, or ten tons of fireworks, according to the conditions of storage and the distance from protected places.

Special licences to be obtained for manufacture or storage of either larger quantities than are allowed by common licences, or for similar quantities under special conditions; these "special" licences to be granted by the local authorities, upon the report of an inspector, and subject to such conditions as to area and description of licensed premises, quantities, distances, and precautions, as the inspector may recommend. Special licences for importation to be granted by the local authorities.

The licencing authorities for special licences are to be:—In the City of London, the Lord Mayor and Aldermen; in the rest of the Metropolitan Board of Works District, the Metropolitan Board of Works; in boroughs, the Town Council; in any harbour, the harbour authority; in counties, Quarter Sessions; in Scotland, the sheriff. For common licences, to be the same, except in an urban sanitary district (not included in a harbour) where the Urban Sanitary Authority is to have the power; and instead of Quarter Sessions, Petty Sessions.

The destruction by explosion of a magazine under a common licence to be at once reported to the inspector, and the existing license to be considered as temporary until the inspector has reported whether the licence should be continued as before, or the licensee should take out a special licence. If two or more buildings of a licensed factory, other than the incorporating mills of a gunpowder factory, are destroyed by explosion, the licensee not to re-erect more than one of such buildings without the written consent of the Secretary of State for Home Affairs, or otherwise than in accordance with such conditions as to mounds, or other precautions, as the said Secretary of State may impose.

The carriage of explosives to be carried on without a licence (except water-carriage in harbours where bye-laws to that effect exist), but under certain statutory "general rules," and all explosives carried to be duly labelled and declared.

Harbour authorities to have power to make bye-laws, subject to approval of Secretary of State, to regulate the navigation and place of mooring of ships, safe stowing and safe keeping of explosives on board; and railway and canal companies for regulating the loading and carriage of explosives over their rail or canal.

"General rules" for the manufacture, storage, packing, and carriage of explosives to be enacted. These rules to be variable only by Order in Council, but no varied rules to be in force unless they have been laid one month on the table of the House of Commons. "Special rules" to be framed by every manufacturer (except small firework makers, who should be provided for by extra rules to be framed by the Secretary of State for Home Affairs), and every holder of a special or sommon magazine licence, or of a special importation licence, if required by the said Secretary of State, for the conduct and guidance of the workpeople in his factory or magazine or place of importation. All "special rules" made as above to be confirmed by the Secretary of State for Home Affairs, who may disallow or add to the same.

Inspectors to be appointed by the Secretary of State for Home Affairs, who are to have power to make such examination, entry, and inquiry, as may be necessary to ascertain whether the provisions of the Act are complied with, and to take samples for analysis of any explosive, or supposed explosive, on tender of payment, and to require railway companies to carry such samples. An inspector to have power in the case of his observing anything unnecessarily dangerous and defective, to give notice to licensee, and require the same to be remedied, subject to an appeal to arbitration (as in the Mines Acts); and, if the matter be, in the opinion of the inspector, urgent, and tend to the bodily danger of any person, to require the same to be remedied forthwith.

Penalties, which may include in some cases forfeiture of licence, to be imposed for a substantial departure from any important condition of the licence, or for making, or storing, or importing an explosive without a licence (where licence is required), or otherwise than in accordance with the terms of such licence, or for wilful neglect, or wilful act, tending to endanger life or limb; with power, if the case is tried on indictment, for the court to forfeit a licence (except in the case of magazines and factories lawfully existing at the time of the passing of the Act).

It is further recommended that the Act should not apply to factories and magazines and explosives belonging to the Crown, or to volunteer storehouses.

The Pharmaceutical Journal.

SATURDAY, JULY 11, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square. Instructions from Members and Associates respecting the transmission of the Journal should be sent to* ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C. Advertisements to Messrs.* CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REPORT OF THE COMMITTEE ON THE ADULTERATION ACT.

WITH somewhat startling promptitude, the Select Committee appointed to inquire into the operation of the Adulteration of Food Act, 1872, has issued its report, and we believe that the majority of those who have watched the proceedings of the Committee with any degree of capability to judge of the merits of the evidence given, will be agreeably surprised at the general fairness and good sense which characterize both the criticism of the Act and the suggestions for its amendment.

With a fresh recollection of the heterogeneous nature of the evidence given by the eighty-seven witnesses examined at the fourteen meetings held by the Committee, it is highly satisfactory to find such a result produced so speedily; and there is much reason for the general public, as well as the trading community, to be grateful to the members of this Committee for the careful and energetic manner in which they have performed their functions.

Considering how amply trade interests were represented on the Committee, it is a high testimony to the practical value of the Adulteration Act to find that the report commences with a declaration that the Committee having considered the matters referred to it, the unanimous conclusion has been arrived at that the Act has done much good. That it has also the means of inflicting considerable injury upon respectable tradesmen, and in some instances of imposing upon them undeserved penalties, is a fact which has become so obvious that its recognition could not be avoided by any impartial inquirers.

In regard to the vexed question of mixed articles of food and condiments, such as cocoa and mustard, it is considered that the evidence tends to show that these articles have been sold to suit the requirements of consumers; that the compounds are frequently made, quite as much to suit the public taste as to increase the profit of the manufacturers. It is therefore proposed to make the sale of such mixtures allowable, upon condition that a legible statement of the fact that they are mixtures is attached to each package when sold, but without the necessity for verbal declaration as well. The statement of the proportion of each ingredient in such mixtures is objected to, on the ground that it could not afford any real protection to the consumer.

The shocking nonsense that has been talked about the innutritious and hurtful qualities of the purified amylaceous preparations analogous to arrowroot, and commonly known by the name of corn flour, has been very properly denounced by the Committee, and due weight has been given to the more sensible evidence that corn flour, when properly used, is a convenient and useful dietetic article, although it is not in itself a perfect food.

One very important suggestion of the Committee is, that when a retail dealer, charged with adulterating any article, shall produce evidence that he bought the article under guarantee from a wholesale dealer, and that he sold the article in the same state and condition that he received it from the wholesale dealer, it shall be in the power of the magistrate to summon the wholesale dealer, as well as the retailer.

We cannot conceive any provision more thoroughly calculated to afford at the same time due protection to the public, and to the retailer who is honestly desirous of supplying pure commodities.

The appointment of some properly constituted authority, to whom appeal can be made in disputed cases, seems to be decidedly approved of by the Committee, and it is suggested that the chemical officials connected with the Inland Revenue laboratory should be entrusted with the decision of such cases. This is suggested in the absence of further information as to any better means of dealing with disputed points, and it has at least the merit of giving definite recognition to a great want as regards the working of the Adulteration Act. We regret, however, that this important point has not been more thoroughly gone into. For reasons we have stated on several previous occasions, we do not altogether concur in the opinion that the duty of deciding disputed cases should be assigned to a special department of the Inland Revenue Board, though we do not in any way undervalue the services rendered by that department in its own sphere.

The admitted want experienced by the Local Government Board of competent guidance in regard to the exercise of its power to confirm or revoke the appointments of analysts appears also to point to the necessity for appointing a special Board for this purpose, as well as for the settlement of disputed cases; and this is one of the things most pressingly necessary for the proper working of the Adulteration Act.

In regard to drugs, there are not any suggestions in the report of the Committee, but it may be assumed that the spirit of the recommendations respecting articles of more general consumption, is intended to apply to the trade in drugs as well, and we have therefore deemed it desirable to place the report of the Committee before our readers in full.

THE IRISH PHARMACY QUESTION.

THE Select Committee entrusted by the House of Commons with the consideration of the Apothecaries' Licences Bill, introduced by Mr. ERRINGTON, has met twice during the present week. On Monday the Committee only met for an hour, and little was done beyond choosing the Chief Secretary for Ireland, Sir MICHAEL E. HICKS-BEACH, as Chairman. On Thursday the evidence of Dr. LEET, Secretary to the Court of Apothecaries' Hall, Dublin; Mr. THOMAS COLLINS, Director of Apothecaries' Hall, Dublin; and Mr. HAYES, the Secretary of the United Chemists and Druggists' Society of Ireland, was taken.

Dr. LEET was first examined, but in consequence of the low tone in which he spoke, notwithstanding repeated requests from the Chairman to speak louder, it was almost impossible for any one but the official reporter to hear much that he said. So far as we could gather, he appeared to object to the Bill on the ground that the English Pharmacy Act was not suited for extension to Ireland. He agreed with the preamble of the proposed Bill, stating the inconvenience entailed on the public in many parts of Ireland in consequence of the deficiency of shops and establishments for the sale of medicines and compounding of prescriptions, but he was of opinion that there was a sufficient supply in large towns. This deficiency, he thought, would be best supplied by the scheme which has been drawn up by the Court of Apothecaries' Hall. He did not wish to say anything against the examinations of the Pharmaceutical Society, but he urged that there were many persons on the English Register who had not passed any examination, and he objected to their being admitted to dispense prescriptions in Ireland. To a question whether dispensers who were good enough for England were not equally good for Ireland, he replied that many unexamined persons were admitted to the English Register by the necessity of circumstances which do not exist in Ireland, where none but licentiate apothecaries are now allowed to dispense physicians' prescriptions. Some surprise was excited by the list of subjects mentioned by Dr. LEET as those in which, at present, it is necessary to pass an examination before gaining the right to dispense prescriptions as an apothecary, and the remark that only in anatomy and physiology was it necessary to attend a second course of lectures, was followed by an audible "Is that all!" from one of the Committee. Of course, Dr. LEET objected to counter prescribing on the part of the pharmaceutical chemists of the Apothecaries' Hall scheme; but in answer to a question whether the creation of such a class would not render it unnecessary for apothecaries to dispense their own medicines, he gave no more definite answer than that the right of apothecaries to dispense was reserved in the scheme of the company. Dr. LEET further said that he thought it was desirable for the Pharmaceutical Society which it had been proposed to establish to be an independent body, and that it was intended to hand over any surplus from the examination fees towards the support of a school of pharmacy; though to judge by the extremely small amount of income from examinations stated by the next witness to have been received by the Apothecaries' Company in past years, such a surplus would not do much good in that respect.

Mr. COLLINS endorsed generally his colleague's evidence, so far as he had heard it. He thought it was necessary that the dispenser of medicines should possess a higher qualification than the mere sellers of drugs and poisons; and admitted that the English Major examination might suffice to ensure this, though he thought the Minor would not. However, unless Mr. COLLINS has an intimate acquaintance with the standards adopted in these examinations, and it did not appear that he has, the force of his remark is not very obvious, for he immediately afterwards declared his ability to make the Minor examination, as it is officially described, as searching a test as the Major. The present dearth of establishments for the compounding of medicines, he attributed mainly—not to the difficult examinations, but to the Irish Poor Law Dispensary system, under which former patients of the apothecary now obtained their medicines gratis. Mr. COLLINS's reason for apothecaries continuing to keep open shop in the event of a sufficient supply of pharmaceutical chemists being forthcoming was one that none but an apothecary would venture to put forward, however near the truth it may be. He said that as soon as the apothecary's consumption of drugs and medicinal preparations was limited to his own prescriptions he would cease to keep many of them, and confine himself to the use of a much smaller number. One main point of this witness's evidence was, the importance attributed to the three years' experience of practical pharmacy required in the Apothecaries' Hall scheme, and it was evident he was ignorant that a similar provision is shortly to come into force in this country. Similar ignorance of the true state of affairs was shadowed forth in a remark that the effect of an extension of the Pharmacy Act to Ireland would be to draw all the Irish students (with their fees) to the school of Pharmacy belonging to the Pharmaceutical Society of Great Britain.

Mr. HAYES objected to Mr. ERRINGTON's Bill, on the ground that the extension of the 15th section of the Pharmacy Act, 1868, to Ireland, making it illegal for unregistered persons to call themselves chemists and druggists, would affect the majority of that class in Ireland. This, it was remarked by the Chairman, was evidently not intended, and of course the reservation of existing rights is a matter of detail that could easily be arranged. He was in favour of the Apothecaries' Hall scheme, as one that he thought promised to provide a School of Pharmacy, and he said that with a few exceptions, especially the reservation of the rights of present assistants to chemists and druggists, the scheme had the approval of the United Society of Druggists.

The Committee is to meet again on Monday next. We believe it is desired that on that occasion some members of the Pharmaceutical Society should attend and give evidence.

AT the Northamptonshire Petty Sessions held last week, the General Committee recommended the appointment of Mr. YOUNG, Pharmaceutical chemist, of Leicester, as analyst for the county. An amendment was moved by Mr. ASHBY ASHBY to the effect that, considering the great expense which would be involved in the carrying out of the Act, no public analyst for this county be at present appointed. On a division, the motion of Lord HENLEY for the appointment of Mr. YOUNG was carried by a majority of 12 to 5.

Mr. YOUNG is also public analyst for the Borough of Leicester, and Counties of Leicester and Rutland.

MR. T. M. DEIGHTON, of Bridgnorth, Pharmaceutical Chemist, and Local Secretary to the Pharmaceutical Society, has been appointed by the Lord CHANCELLOR to be one of the magistrates of the borough of Bridgnorth.

Parliamentary and Law Proceedings.

Charge against a Chemist and Druggist of Adulterating Quinine.

On Thursday, at the police court at Tunstall, Staffordshire, before Mr. H. C. Greenwood, stipendiary magistrate, Mr. W. S. Pearson, chemist and druggist, of Kidsgrove, was summoned for having sold, as unadulterated, some quinine which was largely adulterated with sulphate of cinchonine; the latter being comparatively valueless for medical purposes, and (under the Pharmacy Act, 1868) injurious to health. Mr. Fulford, barrister, instructed by the clerk of the peace for Staffordshire, appeared in support of the charge, and Mr. F. W. Tomkinson, solicitor, for the defence.

Mr. Fulford: I believe the case was before the court a fortnight ago, but I do not know how far it went.

Mr. Greenwood: It was not gone into on that occasion.

Mr. Fulford: Then we will begin at the beginning. This is a charge against Mr. Pearson for having sold to William Gifford, as unadulterated, a certain quantity of sulphate of quinine, which quinine was adulterated with a certain quantity of sulphate of cinchonine. It appears that on the 18th of June, William Gifford, assistant to Mr. Knight, inspector for this division of the county, purchased at the shop of Mr. Pearson, at Kidsgrove, a quantity of quinine. At the time of the purchase, Gifford gave the proper notice to Mr. Pearson that the quinine was to be delivered to Mr. Scott on the 20th of April in order that it might be analysed, Mr. Scott being the county analyst. The analysis was made by Mr. Scott, and I now hand in his certificate.

Mr. Tomkinson: I submit that the certificate is not evidence.

Mr. Fulford: I don't understand what the objection is. The certificate is made evidence by Act of Parliament. The statute of 1872, under which this prosecution is instituted, incorporates the statute of 1860, in which the certificate of the analyst is made evidence, unless there is evidence to the contrary. If evidence is brought forward for the defence to contradict the terms of the certificate, Mr. Scott will then support his certificate by evidence.

Mr. Tomkinson: The certificate is not evidence. The 9th section of the Adulteration Act, 1872, says, "any purchaser of any article of food or drink or drugs in any district, county, city, or borough, where there is any analyst appointed under this Act, shall be entitled, on payment to the inspector or inspectors appointed under this Act, of a sum of not less than 2s. 6d., nor more than 10s. 6d., which shall be accounted for to the local authority appointing such inspector or inspectors, to have any such article analysed by any analyst who may be appointed for such district, county, city, or borough, and to receive from such analyst a certificate of the result of his analysis, specifying whether, in his opinion, such article is adulterated," and so on. In this case the certificate has not been given to the purchaser, but to Mr. Knight. Gifford, not Mr. Knight, is the purchaser; and the certificate is not evidence unless it is given to the purchaser.

Mr. Greenwood: Mr. Knight is the purchaser.

Mr Tomkinson: The learned counsel says Gifford is the purchaser. I dont want to raise these questions unnecessarily, but I want to have an opportunity of cross-examining Mr. Scott.

Mr. Fulford: Mr. Scott is here and you can call him if you like. The usual course is to put in the certificate, and to take it as conclusive unless it is contradicted. If the certificate should be contradicted, then the analyst can be called. I never heard such an objection raised before. The 9th section of the Act of 1872, makes the certificate evidence.

Mr. Greenwood: According to the 6th section of the Act, it is not necessary for the inspector to be the actual purchaser. It simply says he shall "procure and submit samples" for analysis. Thus it is clear that he may procure, either by himself or by deputy, such articles as he suspects to be adulterated, and "shall, upon receiving a certificate stating that the articles of food or drink or drugs are adulterated, cause a complaint" to be made.

Mr. Tomkinson: That is done, and we are here to answer the complaint; but the only way in which the certificate can be produced as evidence is under the 9th section, by being given to the purchaser. The summons, says Gifford was the purchaser. I think, in fairness, the learned counsel should put Mr. Scott into the witness-box.

Mr. Fulford: We will put him in when there is occasion for it. As to the delivery of the certificate to the purchaser, Gifford is the agent to Mr. Knight, and purchased for him. I submit that Mr. Knight is the purchaser.

Mr. Tomkinson: If Mr. Knight is the purchaser, the summons must be dismissed, because it says Gifford made the purchase.

Mr. Greenwood: I have no doubt that we can treat Mr. Knight as the purchaser. The 6th section gives the inspector power to obtain the article either by himself or deputy.

Mr. Fulford: I don't wish to do anything unfair to the defendant. On the contrary, the object is not to take him at a disadvantage, but to have the truth brought out. The only reason I don't put Mr. Scott into the witness-box at present is that I have yet to learn that there is any answer to the certificate. If the defence is no answer to the certificate, I submit the certificate will be sufficient. If any evidence is brought forward in contradiction of the certificate, then by all means have Mr. Scott examined.

Mr. Tomkinson: When an application was made for an adjournment a fortnight ago, it was said that Mr. Scott should be brought forward to give evidence. I have come prepared to cross-examine him. I have Professor Attfield here, and he says the quinine is not adulterated. It will be for you to say, which of the two analyses is the correct one—that which has been made by Mr. Scott or that which has been made by Dr. Attfield. It was my impression when the case was adjourned, that we were to have Mr. Scott put into the witness-box. I cannot understand why there should be an objection to putting Mr. Scott into the box. I say, in fairness to the tradesmen of the county, Mr. Scott ought to be put into the box to substantiate his certificate whenever there is a valid objection to it.

Mr. Greenwood: The certificate is sufficient evidence until it is disputed.

Mr. Fulford: Yes, and if there is anything brought forward to invalidate the certificate, Mr. Scott will at once submit to examination and cross-examination. If Dr. Attfield has made an analysis, it must be shown that he has had before him a sample out of the same bottle as that came from which Mr. Scott analysed. It will not be easy to prove that.

Mr. Greenwood: I shall receive the certificate as evidence, and if there is evidence to rebut it, then Mr. Scott can be called if necessary.

Mr. Tomkinson: I bow to your decision, but in common fairness I think Mr. Scott should be put into the box before instead of after the defence is heard.

Mr. Greenwood: Why did not the defendant, before the purchaser went out of the shop, make him seal up the remainder of the sample and have it analysed, so that there could be positive proof that the two samples analysed were from the same bulk?

Mr. Tomkinson: When a tradesman, who is conscious of having done nothing but what is right, is suddenly called upon, as Mr. Pearson was in this case, he has not the presence of mind to do that which, after sitting in court and listening to a case, he finds would have been desirable.

Mr. Fulford: As soon as there is scientific evidence to invalidate the certificate, I will put Mr. Scott into the box. That will be following the usual course, and I cannot see that any injury will be done to the defendant.

Mr. Tomkinson : I dont wish to continue this discussion, but I must say that the course pursued in these cases is unfair to a defendant. It is very much like the French system of cross-examining a defendant to get evidence against him.

Mr. Greenwood : I dont think I am doing wrong in accepting the certificate.

The certificate was in the following terms, as read to the court by Mr. Thistlethwaite, the magistrate's clerk :—"Quinine : I find the same to be largely adulterated with sulphate of cinchonine, an alkaloid comparatively valueless for those or most of those purposes for which quinine is specially employed. In my opinion the said sample, being largely adulterated, is a drug coming within the meaning of the 24th section of the Pharmacy Act, 1868, which requires all such mixture to be deemed injurious to health."

Mr. Tomkinson : I don't see why the county analyst should undertake to decide in his certificate what comes within the meaning of the Act of Parliament.

Mr. Fulford : The 24th section of the Pharmacy Act, 1868, applies to "all articles usually taken or sold as medicines, and every adulteration of any such article shall be deemed an admixture injurious to health, and any person registered under the Act who sells any such article adulterated shall, unless the contrary be proved, be deemed to have knowledge of such adulteration." So that it is not necessary to prove the ingredient is of itself injurious.

William Gifford, examined by Mr. Fulford.

Are you an assistant to Mr. Knight, an inspector under the Adulteration of Food Act ?—I am.

On the 18th of April did you purchase, at the shop of Mr. Pearson at Kidsgrove, some quinine ?—I did.

How much ?—A shilling's worth.

Who supplied you ? —The master.

When you purchased it, did you say what it was for ?—Yes, I told him I wanted it for the purpose of an analysis. I told him it would be delivered at Mr. Scott's residence, Tattenhill Road, Wolverhampton, at seven o'clock on the 20th of April.

What did you do with it ?—I delivered it to the inspector.

What sort of a parcel was it in ?—A small paper parcel.

Was it sealed ?—Yes.

Who sealed it ?—It was Mr. Pearson's seal.

Was it in the same condition when you delivered it to Mr. Knight as when you received it from Mr. Pearson ?—Yes.

Cross-examined by Mr. Tomkinson.

Whom did you see when you went into Mr. Pearson's shop ?—Miss Pearson.

Did you ask for sulphate of quinine ?—Yes.

Did she go to her father and bring him to the shop ?—Yes.

And did he come to serve you ?—Yes.

When you told him you wanted it for analysis did he show you the bottle from which the quinine was taken ?—He did.

Is this the bottle ?—It is something like it.

Did he tell you whose it was ?—He said it was Howard's best quinine, and that he had bought it as pure.

Do you know how many grains you bought ?—No, sir ; he did tell me, but I cannot say.

Were there twenty grains ?—I cannot swear.

At all events, it was a shilling's worth ?—Yes.

Did he say if that was not enough he would sell you more ?—Yes, he said so, and that he had no doubt it was pure.

Do you know if this was the bottle ?—It is something like it.

Did he show you the label ?—He showed me a bottle like that.

Mr. J. E. Knight, examined by Mr. Fulford.

You are the inspector under the Adulteration of Food Act for this division of the county ?—Yes.

On the 20th of April, did you receive from the last witness a packet of quinine ?—Yes.

What did you do with it ?—I delivered it to Mr. Scott, at his house, at seven o'clock in the evening.

Was it opened ?—Yes, it was opened by me.

Was it divided ?—Yes, and Mr. Scott kept the larger portion.

Have you the remainder ?—I have.

Was it sealed ?—Yes, with Mr. Scott's seal.

What was the number placed on the packet retained by Mr. Scott ?—238.

Is there any other number than 238 on that packet ?—No ; it was Mr. Pearson's writing, I suppose.

238 is on that ?—That is my number.

Some time after you delivered the packet to Mr. Scott, did you receive a certificate of the result of the analysis ?—I did.

Is this it [certificate produced] ?—That is the certificate.

The number on the certificate is 238 ?—Yes.

And that is the number on the packet ?—Yes.

No cross-examination.

Mr. Tomkinson : On behalf of the defendant, I shall have to ask your careful consideration of the evidence I intend to bring before you. I admit that I labour under the difficulty of proving that the same quality of quinine was sent for analysis to Dr. Attfield as was analysed by Mr. Scott. But you have the admission of Gifford that when he purchased the quinine from the defendant it was taken from a bottle similar to this, and he was told that it was Howard's quinine, which was sold as being pure. What I propose to do is this : to show that Mr. Pearson took the remaining portion of the quinine that was in the bottle after Gifford purchased some, and that it was sent in a registered letter to Dr. Attfield for analysis. I shall put in the witness-box Miss Pearson, who assists her father in the shop, and she will say she has never seen in the shop any cinchonine, with which this quinine is said to have been adulterated. Messrs. Howard have peculiar marks for the different preparations of bark. Sulphate of quinine bears a red seal, and is wrapped in a different paper from that used for the other alkaloids. Sulphate of quinidine is not quite so strong. It bears a dark green seal, and is wrapped in a buff-coloured paper. The salt of cinchonine is wrapped in blue paper and has a yellow seal ; and Miss Pearson will tell you that on no occasion has she seen a bottle with a blue seal and wrapped in a yellow paper in the shop.

Mr. Greenwood : I don't know what use that is. How can Miss Pearson tell what may have been put in it?

Mr. Tomkinson : It will be one ingredient in the case to show that, at all events to her knowledge, the preparation of cinchonine never was in her father's possession. I put that forward to strengthen the evidence. Gifford admits the quinine which he bought was taken from a bottle like this in which Messrs. Howard send out quinine ; and when the case was adjourned, a portion of the quinine was taken out of the same bottle, sealed up, and sent to Professor Attfied for analysis by him. Dr. Attfield says it is pure commercial quinine. If I prove that, I think you will dismiss the summons ; at all events, unless the learned counsel puts Mr. Scott in the witness-box. There is one other point which I wish to urge before you, and I think it is a very good defence to this summons. Quinine is made from Peruvian bark. The bark varies in quality ; and, of course, the finer the quality, the larger the proportion of quinine produced. The specimens which Dr. Attfield has brought down are good specimens. Now, from the bark four different articles are produced—first quinine, then quinidine, then cinchonine, and then cinchonidine—and it is impossible to make one of these without having in it traces of the others. Therefore, my contention is that all these chemical preparations being obtained from bark, even supposing in the quinine there was some cinchonine, it would not be adulteration within the meaning of the Act of Parliament. The definition of adulteration would be something added to a commodity for the purpose of either increasing its bulk or cheapening its price. Although cinchonine is a little less in price than quinine, yet both are produced from the same material. It is not as if cinchonine was made from a different bark; it is made from the same material; and, therefore, it is nothing that is added to the quinine; but, being a component part of the raw quinine, it is not an adulteration of quinine. After hearing the evidence of Dr. Attfield, I think you will say it is not an adulteration. Dr. Attfield has had extensive experience. He is a Fellow of the Chemical Society, Professor of practical chemistry to the Pharmaceutical Society, and is in fact one of the first authorities in England on this subject. It will be for you to consider whether the analysis has been properly made, and whether there is not proof that the sample of the quinine which was sent to Dr. Attfield was the same as the sample sent to Mr. Scott. Then, supposing there to be cinchonine in the quinine, you will have to consider whether it has been added to it for the purpose of increasing the bulk or lessening the price. This is a matter which ought to come before the court, but, having investigated it, you will, I feel sure, dismiss the summons.

Miss Louisa Pearson, examined by Mr. Tomkinson.

I believe you attend to your father's shop, and assist him in his business?—Yes, sir.

Do you remember William Gifford going to the shop on the 18th of April to purchase some quinine?—Yes.

You called your father to supply it to him?—Yes, sir.

I believe you well know the appearance of the quinine bottle?—Yes.

Had it a red cork?—Yes.

How long have you been assisting your father in his shop?—For some years.

Have you upon any occasion seen in your father's shop, or in his possession, any bottle with this peculiar yellow wax seal upon it?—Not till last night.

[This was the kind of bottle in which Messrs. Howard send out a salt of cinchonine.]

Your father got it last night?—Yes.

Have you seen any preparation of quinine except in the bottles with the red seal?—No, never, except in those bottles with the red seal.

Mr. Greenwood: Do you know the difference between quinine and cinchonine?

Witness: Not without seeing the bottles.

Mr. Greenwood: If any cinchonine should be in a bottle, you would not know it from quinine?

Witness: I think not. I never sell it without going to my father about it. I should not know how to sell it.

Mr. Fulford: You know nothing about putting them in bottles?

Witness: No.

Mr. John Parker, examined by Mr. Tomkinson.

Are you a draper residing at Kidsgrove?—Yes, sir.

Close to Mr. Pearson's?—Yes, near to Mr. Pearson's.

On Saturday, the 20th of June, did Mr. Pearson call you into his shop?—He did, sir.

And did you see him make up a packet out of a bottle?—I did, sir.

And wrap it in a pink paper?—Yes.

Did you mark the bottle from which it was taken?—Yes.

Is the bottle produced the same? Do you recognize it?—Yes, sir.

By his directions did you seal up the contents of the bottle?—Yes.

Did you put the seal upon it?—I did.

Did you endorse it?—I think Mr. Pearson endorsed it.

Is this the parcel that was made up?—Yes, and I see the endorsement is mine.

Did you put that in an envelope addressed to "Dr. Attfield, 17, Bloomsbury Square, London, from W. S. Pearson, Kidsgrove"?—Yes.

Was this put in another envelope, addressed to Dr. Attfield, and posted by you at Kidsgrove?—Yes.

Did you register the letter, and is this the envelope?—Yes.

Did you get a receipt for the letter?—I did.

Will you produce it?—[Receipt produced.]

Mr. Fulford: I shall not dispute that.

Professor Attfield, examined by Mr. Tomkinson.

Do you reside at 17, Bloomsbury Square, London?—I am Director of the chemical laboratories there.

You are professor of practical chemistry to the Pharmaceutical Society?—I am.

Did you, on the 21st or the 22nd of June, receive that envelope [produced] by post?—Yes, on Monday, the 22nd of June.

In that envelope did you find a small paper containing quinine?—I found a second envelope, sealed, and in that I found this small packet [paper produced], which was also sealed and which I opened.

I believe you are practically acquainted with the chemistry of quinine?—Yes; I have been employed by the English and other Governments to examine quinine which has been purchased from firms such as Messrs. Howard's.

You have had a great deal of experience in testing it?—I have.

Will you explain to the court the production of quinine and the other bodies extracted from bark? — Perhaps if you explain it in your own language it will be most satisfactory.—Quinine is a medicine obtained from cinchona bark, sometimes called Peruvian bark or quinine bark. This Peruvian bark not only contains quinine, but other closely allied substances — namely, cinchonine, quinidine, and cinchonidine. The similarity of the names indicates the close alliance of the substances with each other. They are dissolved out of the bark. One bark will yield quinine chiefly; another will yield the other medicines chiefly.

Is it possible to make quinine without a trace of the other substances being found in it?—It would be possible to be done by a professed chemist, no doubt; but practically and commercially it is impossible to obtain quinine from bark without it containing a small amount of these other alkaloids, say less than one per cent.

Mr. Greenwood: Do I understand you to say quinine might contain an amount of cinchonine, but not more than one per cent?

Dr. Attfield: One per cent. *might* be present, but I have not found that proportion.

Mr. Tomkinson: Are these alkaloids all derived from the same description of bark, but of different qualities?—They are all derived from cinchona bark.

In your opinion would the presence of cinchonine with quinine be an adulteration? Is not cinchonine a valuable medicine?—With regard to the medicinal character of cinchonine, the Government a few years ago appointed a commission to inquire into the value of quinine relative to these other allied medicinal substances, quinidine, cinchonine and cinchonidine. The commission, appointed by Her Majesty's Secretary of State for India, gave a preliminary report in 1866.

Mr. Fulford: I don't like to object, but is this evidence?

Mr. Tomkinson: It is a matter of professional opinion.

Dr. Attfield: This commission was composed of the leading medical men in the Madras Presidency, and they reported as follows: "The main conclusion which the members of the commission have derived from the data before them is, that the alkaloids hitherto but little valued in medicine are scarcely, if at all, inferior as therapeutical agents to quinine." In 1867 the Bombay commission reported in similar terms; and in 1868 there was issued a final report, in which they state: "Most of the medical officers employed in using the alkaloids seem fully impressed with the belief that they are equally or very nearly as efficacious as ordinary quinine; and, as already shown, the mass of information furnished in the tabular reports proves that such belief is well founded."

Do you assume from that that cinchonine is not "comparatively valueless"?—A dose of cinchonine would be four grains, where a dose of quinine would be three grains. If given in that proportion, it is admitted to be as good as quinine.

I believe you have had considerable experience in the examination of the books of Messrs. Howard?—I have had occasion to go to Messrs. Howard's to select samples taken from bulks of alkaloids ordered by different governments. I therefore know the mode in which Messrs. Howard carry on business.

I believe sulphate of quinine is lighter than sulphate of cinchonine?—One ounce of sulphate of quinine would fill a bottle like the one you have now in your hand. One ounce of sulphate of cinchonine would just half fill the bottle. Any porter or packer, though not at all acquainted with the chemistry of the substances, would by the bulk know there was something wrong if a one-ounce bottle of quinine contained a really "large" proportion of cinchonine. A small quantity would make little difference.

If "largely adulterated" with cinchonine the bottle would not be full?—It would not.

Mr. Fulford: But you could fill it.

Dr. Attfield: In that case the bottle would contain more than an ounce.

Mr. Fulford: I don't dispute that Howard's quinine generally is perfect; but there is nothing to show that this quinine was supplied from Messrs. Howard. It came from a wholesale dealer to the defendant. It did not come direct from Messrs. Howard.

Mr. Tomkinson: We shall show that it is pure.

Mr. Fulford: We don't say Howard's is not good.

Dr. Attfield: My knowledge of the barks which Messrs. Howard manipulate, enables me to say that only one ounce of sulphate of cinchonine is by them produced for every 125 ounces of quinine; so that if they mixed the whole of the sulphate of cinchonine they make with their sulphate of quinine, it would not amount to one per cent.; but, further, I know from examination of their books that every ounce of sulphate of cinchonine they make, is sold by them separately as sulphate of cinchonine, and with regard to any accidental admixture of cinchonine with quinine, I am sufficiently acquainted with Messrs. Howard's factory, to know that it is impossible that they can be mixed accidentally; for they manipulate these different alkaloids in different rooms, dry them in different rooms, and keep them in different kinds of vessels. Quinine is kept in tin vessels; cinchonine in earthenware jars. They use bottles of different capacities, and labels of different colours, and they seal the bottles with different coloured wax. So that in these, and other ways, they take every possible precaution against any accidental admixture.

Examination by Mr. Tomkinson continued.

In your opinion is it impossible to have them mixed there?—Practically it is impossible.

Did you analyse the quinine you received in the registered letter?—Yes.

Will you just tell the court what you found—whether it was pure or not?—I found it to be pure. It not only did not contain "a large quantity of sulphate of cinchonine," but it did not contain one per cent. of the three alkaloids (cinchonine, quinidine, and cinchonidine) put together. As to cinchonine, it contained a mere trace.

In your opinion is it pure sulphate of quinine?—It is.

Cross-examined by Mr. Fulford.

Is there much difficulty in distinguishing cinchonine from quinine, if present?—Yes, there is some difficulty.

The test of the British Pharmacopœia, is that a good one?—It is a good test, but rather lenient.

If cinchonine were detected by that test, you would have no doubt cinchonine was present?—None.

What is a fair and liberal allowance to make for the accidental mixture of cinchonine with quinine in the manufacture?—I never found one per cent., but we may say one per cent.

If you found ten per cent., you would not say that was a fair amount to allow either from accident or the process of manufacture?—Not if it were Howard's quinine.

Or anybody else's?—An article has been produced, even under Government sanction, which consists of mixed alkaloids or cinchona principles taken from the bark, and it differs in composition according to the bark from which it is obtained; but if an article purported to be sulphate of quinine and contained ten per cent. of cinchonine, I should say it was a bad sample of sulphate of quinine.

If you found five per cent. of cinchonine in quinine, should you say it was Howard's?—No. If I found five per cent. of cinchonine, I should say that the sample was faulty or that the cinchonine had been added to the quinine.

Mr. Greenwood: Do you mean that if it contained five per cent. of cinchonine it must have been added, or that it could not have been Howard's?—Yes.

Cross-examination continued.

Commercially is sulphate of cinchonine comparatively valueless?—It is about one fifth of the money value of quinine.

What was the date of the report you referred to just now?—The Madras report is dated 1866; the Bombay report 1867, and the final report of the Madras commission, 1868.

Cinchonine is not allowed as an official medicine, is it?—There are many medicines not in the Pharmacopœia which are largely used by medical men. Cinchonine, especially in the form of "muriate" of cinchonine, is largely used by Government officials and by medical men generally. Probably these alkaloids——

I understood you to say in the quinine which you analysed you found no trace of cinchonine?—None worth mentioning. I should think these alkaloids will be in the next edition of the Pharmacopœia, because they are becoming recognized as important medicines. The three alkaloids allied to quinine have not been used very long as medicines, and we should not expect to find them in the Pharmacopœia of 1867. The official reports were only issued about that time.

Does cinchonine give the phenomenon of fluorescence?—No. Solutions of some of these alkaloids have a fluorescent appearance resembling that of the common mineral, fluor spar.

Do they all produce the same effect?—No.

Does the appearance of cinchonine differ from the flourescence of quinine?—The solutions, yes.

[*Bottle produced and shown to witness*].

Witness: I would not judge from appearance alone, but I should think that from the fluorescence quinine is there dissolved in diluted acid. It is sulphuric acid which converts the quinine itself or cinchonine itself into sulphate of quinine or sulphate of cinchonine.

Do I understand you to say that the tests mentioned will show the amount of cinchonine?—Everything depends upon the way in which the tests are applied.

I assume it to be by a man of experience?—Well, it does want some experience to apply it correctly.

If by this test a man of experience—I mean a man who has been a practical analyst for twenty years—arrived at the conclusion that there was at least five per cent. of cinchonine present, what would you say?—He may have been a practical analyst twenty years, and examined articles of food or drink, and yet not have had much experience in drugs.

Do you think he could make a mistake?—I do, unless he had been accustomed to examine quinine.

Re-examined by Mr. Tomkinson.

I suppose in testing this a great deal depends upon the warmth or coldness?—Temperature has a great deal to do with chemical analysis.

Mr. Greenwood: What would be the effect of temperature in this case?

Dr. Attfield: Temperature does not so much affect analyses of quinine as some other substances.

Would it make any practical difference?—If quinine were tested when the solution of it was heated, or even warm, then a substance would be obtained which might be mistaken for cinchonine. One must have considerable experience to test it thoroughly and properly.

This was the case for the defence.

Mr. Fulford: One ground of the defence is that cinchonine is useful as a medicine, and thus that it is not an adulteration; but I wish to call your attention to the second section of the Act of Parliament, showing that it is not necessary that the ingredient should be injurious. That section applies to drugs, as well as to food and drink, and the latter part of it enacts that every adulteration of an article used as medicine shall be deemed an admixture injurious to health, and any person selling such adulterated article must be deemed to have knowledge of it unless the contrary is proved. Therefore, whether cinchonine is useful or not, is quite immaterial to the case. If it is present in an article sold as quinine, it is an adulteration within the meaning of the Act, and the defendant is guilty of an offence, and must be convicted.

Mr. Greenwood: You mean admitting that there is only one per cent.?

Mr. Fulford: I don't say that; I mean if there is an appreciable quantity. If the quantity was only one per cent., I would admit it was pure. Dr. Attfield admits that if there was five per cent. present, there must have been an adition made to the quinine; and if five per cent. of cinchonine has been added, then there has been an offence committed. Mr. Pearson is charged with selling as quinine what we say is a mixture of quinine and cinchonine. With respect to the analysis of Dr. Attfield, it is difficult to prove that what he analysed was the same as that analysed by Mr. Scott for the prosecution. The evidence of Miss Pearson is not sufficient to prove this.

Mr. Greenwood: I attach no importance to the evidence of Miss Pearson. It does not bear materially on the case.

Mr. Fulford: With respect to this particular sample of quinine, I don't know where it came from. The label on the bottle is no doubt Howard's, and so is the seal, but the quinine is not proved to have come from Howard's direct. It has come from a second house.

Mr. Tomkinson: You should not take advantage of a friendly admission.

Mr. Greenwood: It may be that the wholesale dealer adulterates, and the retailer suffers.

Mr. Fulford: Just so. The manufacturer may have sent out the quinine in a pure state, and the wholesale dealer may have supplied an adulterated article. The adulteration need not necessarily have been at Howard's. No doubt Howard's quinine is of an excellent character, and Dr. Attfield has told the court that he has analysed many specimens, and has not found so much as one per cent. of cinchonine present in Howard's. The question is, whether the sample which has been sold has been tampered with after leaving Howard's. I have no desire to keep anything back, and I will place Mr. Scott in the box to give the result of his analysis; the only object of the prosecution being to see whether these articles are pure or not. Mr. Scott will tell you the process and the result of his analysis; and it will be for you, after hearing him, to say whether you have any doubt that the sample which he analysed was adulterated or not. I don't think he will pledge himself to the precise quantity of cinchonine that was found in the quinine, because he tells me these substances were not correctly mixed, and the result of his experiments varied. But he will pledge himself that he found present considerably more than one per cent. of cinchonine. There is still in the possession of the court the remainder of the sample which was purchased at the the defendant's shop; and if there is any doubt that Mr. Scott's analysis is correct, it is within the power of the court to order that that which remains shall be analysed by anyone whom the court may think fit to choose. The sample sent to Dr. Attfield was forwarded a considerable time after the purchase was made by Gifford. I don't wish to cast any imputation upon anyone, but it don't follow that the sample purchased by Gifford and the sample sent to Dr. Attfield came out of the same bottle. There may have been a fresh supply. Gifford bought some quinine on the 18th of April. It was not till the 20th of June that the sample was sent to Dr. Attfield.

Mr. Tomkinson: Until the summons was returnable we did not suppose for a moment but that it was pure.

Mr. Greenwood: It is a similar case to Pendleton's; and it naturally arises in consequence of the defendant not having taken the proper course.

Mr. Fulford: The object of retaining a portion of the commodity analysed by the county analyst is to have it submitted, if necessary, to some one else—some other competent man—and there is a specimen which can be so analysed.

(*Mr. Wentworth Scott, examined by Mr. Fulford.*)

Are you the public analyst for the county of Stafford?—Yes.

Have you been a practical analyst for nearly twenty years?—Very nearly. Since I left college.

Have you devoted yourself to analysing food and drink?—Chiefly.

Have you had much experience in the analysis of drugs?—I have analysed a great deal, both for the Indian Government and private individuals. I have issued reports and contributed papers to the Pharmaceutical Conference.

Have you made many experiments with cinchona bark?—I have, and of the alkaloids obtained therefrom.

On the 20th of April did you receive from Mr. Knight a parcel containing quinine?—I did.

It was divided and you retained a part?—Yes, in the usual way.

Did you analyse the half?—I did.

Is the certificate which has been read the result of your analysis?—Yes.

In that you mention that the sample was "largely" adulterated with cinchonine?—I do.

How much per cent. was cinchonine?—Certainly ten per cent. I do not pledge myself to the fraction of a grain, because I should have preferred to have had a larger sample bought, and have more materials to work upon. Still the result remains the same. I pledge myself certainly to nine or ten per cent. of cinchonine.

Mr. Greenwood: "Largely," the word used in the certificate, is very indefinite. If you will state the amount in your certificates it will be better.

Mr. Scott: I will do so in future. The object of omitting exact figures was that I wish to leave myself a small sliding scale. If I gave decimals a two hours' cross-examination might be made.

Mr. Greenwood: You might leave a margin.

Mr. Scott: I will do so in future.

Examination by Mr. Fulford continued.

You are acquainted with Howard's quinine?—Very well.

Have you analysed their quinine?—I have. They have frequently been good enough to supply me with specimen samples for lectures or private research, and I have bought articles, and have also taken samples from wholesale houses. I am very well acquainted with Howard's make.

How much cinchonine is there in it?—It varies. I have never found so much as one-third of one per cent., but I don't say it might not happen.

What is your opinion as to this quinine coming from Howard's?—The whole of it could not have come from Howard's, and I am not aware that they send any out in admixture.

[Reference to the British Pharmacopœia.] This is the official test. Did you use it?—I used that in a supplemental way because it is the official test. It is by no means so correct a test as others, but I have used it because it is the official test. The sample marked "238" did not answer to that test, which is a rough one.

Have you any doubt that in the sample you examined cinchonine was present to a greater extent than it ought to be?—No.

Cross-examined by Mr. Tomkinson.

How many grains had you to begin with?—I don't remember.

Did you weigh the quantity you took out of the sample?—Certainly.

How many grains have you?—I have not weighed the residue. I took some from the parcel and weighed from my own portion.

How much did you take of what was given to you?—About half.

What weight was it?—I don't know what it weighed.

Was it five or ten grains? Can you tell to a few?—I should think about five grains.

How much have you left in your own possession?—A very small portion.

How many grains would that be?—I don't know. I have not looked at it lately.

Can you tell us to three or four?—There might be one or three; something like that. I really cannot tell exactly. I know there is just some.

If you might have three, then in reality you used seven or eight grains in the testing?—Possibly; I cannot say.

You say you found some traces of cinchonine in it?—Yes.

Did you analyse the cinchonine?—What do you mean by the term?

How did you test that it was cinchonine?—By the usual tests, microscopically and otherwise.

[Book produced, and woodcuts of sulphocyanides of alkaloids exhibited.]—Witness: I don't pin my faith to microscopical woodcuts, but they give a rough idea.

These are wood plates?—I should think so.

You say you tested the quinine: what was the first test?—The first was to dissolve a little in water. Chemists first endeavour to find out what is in the mixture; then how much of it.

What then?—I took a small portion and dissolved it in acidulated water. After allowing that to crystallize spontaneously, I examined it under a microscope. There were some forms amongst the crystals produced which struck me as being what I used to see in pure samples of Howard's various alkaloids.

Had it the appearance of being dirty?—No, it had not.

What had it the appearance of?—It had the appearance of some other alkaloid, but not that of quinine.

What was the next test?—Then I took a small weighed portion.

How much?—I think three grains.

Do you keep any record?—Yes; but I merely give you the general results.

Have you the record with you?—No.

Well, you took three grains: what did you do with that quantity?—I dissolved it in a small portion of acidulated water.

How acidulated?—With sulphuric acid; and I noticed that it did not disappear or dissolve so quickly as I expected; that is, so quickly as would Howard's or some other good maker's quinine pure and simple. It was less soluble than other samples which I have analysed.

Had it a blueish tint?—Yes.

And looked like quinine?—So it would if it had only had a small trace of quinine in it.

[Bottle produced.] Is that the specimen?—No, that is simply to illustrate fluorescence.

Have you analysed the quinine from which that is taken?—I have at some time ascertained it to be pure. I know it was pure.

Did you warm the quinine a little to see if it undergoes a change?—No.

After you had dissolved the three grains in water, what did you do next?—I added a little ammonia till no further precipitation was produced.

What further?—I then added in the usual manner a portion of carefully dried, purified ether.

Where did you get the ether from?—From a bottle in my laboratory.

No spirit of wine in it?—No.

Do you know it is pure?—Yes, from my own knowledge I am able to say everything I use for the purpose of analysis is pure.

Mr. Greenwood: Do you test them first?

Mr. Scott: Undoubtedly.

Cross-examination continued.

How much ether did you use?—I forget how much, but I should think rather over a dram.

What was the effect of the ether?—I should have said I did not add the ether immediately. If the quinine had been pure the whole ought to have been soluble in ether without difficulty.

You mean it would have dissolved at once?—With a little shaking and a little time it would have dissolved very readily.

After you had given it a little shaking and a little time, did it all dissolve?—It did not.

What portion of it was left?—A small portion was left, which I then put into a small filter, so as to get rid of the ether on the one hand and the water on the other. From this portion, which was weighed and which formed one of the experiments, I found some idea of what proportion was cinchonine. I proceeded to apply some of the usual colour tests, as they are called, for the alkaloids, more especially cinchonine, and more particularly the one which is referred to in Dr. Attfield's work. I found there was no doubt that that portion which was insoluble was cinchonine.

You think that?—I don't think, I am perfectly sure about it.

How much would there be left after you had got the ether and the water away?—I did not accurately weigh that portion.

If you did not happen to weigh it, how can you make it ten per cent.?—That was referring to one portion of two or three grains. Taking the other two portions of a few grains each, which I did weigh, they showed nine and ten per cent. of cinchonine. I gathered that the sample had not been perfectly mixed.

Mr. Greenwood: Do you mean the adulterated article?

Mr. Scott: Yes, sir.

Cross-examination continued.

Was that the only test you applied?—By no means.

What were the other tests?—I took a portion of this body, which appeared to give reactions of cinchonine.

How much? Did you weigh it?—I had no occasion to weigh it.

What did you do with it?—I washed it with a solution of what I knew to be sulphate of cinchonine. The object was to wash away any sulphate of quinine that might be present.

Well?—Then, upon dissolving a small portion of that in water, I applied the usual test of fluorescence, and obtained no signs of that colouring which would have shown quinine there. I tested to see if quinine was in it, and no portion of it was quinine. Then I placed a small portion within a polariscope, and I found a ray affected as quinine is not affected, and as cinchonine is affected. I have made myself acquainted with these effects in the polariscope, and therefore I satisfied myself as to the presence of cinchonine.

Were all these tests applied on the fraction of a grain of substance you extracted?—Yes, the microscopic, the chemical, and that with the polariscope.

With respect to the quantitative tests, how much quinine did you have?—I think I used about five grains for the two experiments.

How much did you use in your first experiment?—I don't see your object.

My object will appear: I want you to answer the question. How much did you use in the first of your two quantitative experiments?—You want to get out the point that I have not had enough to work upon. In answer to that, I will say if you give me one grain it is sufficient to tell whether there is any cinchonine present in the quinine. But I would not pin my faith to any exact proportion in this sample, because one experiment gave me a larger proportion of cinchonine than another did. I simply say, it is largely adulterated with cinchonine, and certainly to the extent of ten per cent. I used, I should think, about seven grains in all.

I want to know how many grains you used?—They were divided into two experiments.

Do you know how much quinine was washed away? Did you weigh it?—I did not.

Did you weigh the residue after the quinine was taken away?—Yes.

What is the weight?—I don't know. I have it, and my results are based upon it, but I don't know it at this moment.

Mr. Greenwood: In one experiment you found a larger proportion of cinchonine than in the other?

Mr. Scott: Yes, sir.

Mr. Greenwood: Does that show that it had been added, and was not the result of incorrect manufacture?

Mr. Scott: Yes, and for this reason: if the alkaloids were all crystallized together I should expect, in the same temperature, and with no difference in the crystals, that the analysis would not have varied to that extent. It seemed to have been a mixture of comparatively pure sulphate of quinine, with crystals of sulphate of cinchonine, but that the mixing was badly done.

Mr. Fulford: Would it be possible for nine or ten per cent. of cinchonine to be present in the quinine at the time of the manufacture, without the wilful intention of the manufacturer?

Mr. Scott: It could not have been left there by the accidents of manufacture. Some time ago, Mr. Howard, at Bristol, admitted a mistake, but I will answer for it he would not admit such a mistake as this.

Mr. Fulford: Therefore it must have been either intentionally not extracted at the time the quinine was made, or put in afterwards.

Mr. Scott: Yes; there is no doubt about the presence of cinchonine in large quantity.

This being the whole of the evidence,

Mr. Greenwood said: It is quite clear that, if what Mr. Scott says be true, the sample sent to him was different from that which was sent to Dr. Attfield for analysis. Before I decide this case, I must have a certificate from another chemist, to whom the portion under seal in the possessson of the court must be sent.

It was then decided that it should be sent to Dr. Paul, of London, for analysis, and the case was consequently adjourned.

Removal of Cream not an Adulteration.

Last week, *Thomas O'Connor*, a cowkeeper, of Fulham, was summoned for selling as unadulterated a quantity of milk which proved to be adulterated. Mr. Burge, the analyst, said he examined the sample, and the result was that he found nearly all the cream had been extracted from it. He argued that it was an offence to sell anything which did not come from the cow. Mr. Ingham inquired the meaning of the word "adulterated." The extraction of a valuable quality was not, in his opinion, an adulteration.—Mr. Stainforth, who defended, referred the magistrate to the section in the Act of 1872, which used the words "every person who shall wilfully admix."—Mr. Ingham thought there must be a mixture of some matter with the article of food to prove a case of adulteration.—Mr. Burge said the magistrate's decision would tend to improve the Act which was forthcoming.—The summons was dismissed.

Copper in Preserved Vegetables.

At the Brentford Petty Sessions, on Saturday, July 4, George Thomas Melsom, provision merchant, of Ealing Broadway, was summoned under the Adulteration Act, for selling a tin of preserved green peas, the same being adulterated with copper to improve their colour. Mr. Milton appeared for the prosecution, and produced a certificate from Dr. Redwood, the county analyst, which stated that the peas were adulterated with copper and injurious to health if used as food. A gentlemen who gave his name as Thomas Owen Kilsey, of 34, King William street, stated that he represented the firm importing the peas from France, and that on hearing of the case he telegraphed to the exporters, who stated that the peas were not adulterated in any way, and that a certificate from the prefecture of police was on its way to England to prove this. Mr. Milton asked for the full penalty of £20. The Bench held that a stop must be put to such poisonous traffic, and fined defendant 40*s*. and 8*s*. costs.

Suicide by taking Oil of Vitriol.

It is reported that on last Saturday week a Mr. Fletcher—better known as Dr. Fletcher, of Rainford—committed suicide by taking oil of vitriol. It appears that about Easter last the doctor lost his wife, and since his bereavement he had been very much unsettled, and had taken to indulging freely in liquor. It is supposed that he poured the poison into a wine glass, drank it off, and then laid himself on the bed, where he was found.

Female Students.

Sir,—Kindly give me the opportunity of repudiating the charge of exceeding my duty in endeavouring to comply with the requests of lady-pupils, and of declining the high privilege of taking either side in the controversy about female students.

On page 12 of your last number, a member of the Council states that when I mentioned the application of two ladies to be admitted to my class as well as to the classes they are already attending in the School of Pharmacy, I added that I had found for them a ladies' room, and he thought that in so doing I had gone beyond my province. It was not I who suggested that the housekeeper's cloak-room might serve as a cloak-room for the ladies.

If I were director of private instead of public laboratories, and two ladies who were already attending colleagues' classes and were using the rooms of an adjacent Institution, applied to me for a month's instruction in practical chemistry for two hours daily, I should certainly admit them. If, at the end of the month, I found that the plan of having a mixed class did not work well, I should not renew the ladies' tickets nor again admit female students. If the plan worked satisfactorily, I should continue it.

As to the question of whether I should be doing good or harm to pharmacy by the plan, I have yet to learn that such a question is, or even is ever likely to be, of such proportions as to induce me to trouble myself one way or other about it.

John Attfield.

Carbolic Acid Suppositories.

Sir,—I have written to thank Mr. Pratt for the suppositories that he kindly sent to me, and to which he called attention in a recent issue; but he has not answered my first query as to how much powdered starch he found to be "a sufficiency." I find that the specimens weigh, as Mr. Pratt states, sixteen grains each, an equivalent of exactly one twelfth of the carbolic acid and soap prescribed in the Brit. Pharm. Addendum. It is, therefore, hardly clear to my mind how Mr. Pratt could have followed "the simple directions" of the Pharmacopœia in adding "sufficient starch to form a paste of suitable consistence," when the weights of the suppositories, according to his own showing, are equivalent only to the carbolic acid and soap, *minus* the starch. I find that they are more apt to increase than to diminish in weight by keeping. Mr. Pratt's specimens are softer than the mass that I produce by mixing the prescribed quantities of properly powdered soap and carbolic acid, but of similar consistence to the mass that I produce by using partially dried and coarsely powdered soap; still they are much too hard to be worked "easily" or to finish nicely.

The ready solubility of such suppositories after administration is very doubtful.

T. Howell Williams.

44, *Seven Sisters Road, N.*
June 30th, 1874.

Scammony.

Sir,—In your last number "Henry Brown, L.R.C.P., L.R.C.S., etc.," says that, at the recent scammony trial, I did not correctly quote from the British Pharmacopœia respecting the proportion of resin in scammony. He reminds you that the official numbers are 80 to 90 per cent., and is sorry that in answer to the question "as the highest to be expected," I said "80 per cent. is mentioned in the British Pharmacopœia."

Mr. Brown has simply misunderstood the report of the case. I was proceeding to give the proportions of resin recognized in the British, French, and American Pharmacopœias, and had *already*, as Mr. Brown will see by the report, said that "80 per cent. is mentioned in the British Pharmacopœia," when the learned advocate interrupted me with the words, "as the highest to be expected." I continued my answer respecting the proportions which would stand official scrutiny in Great Britain, France, and the United States, and was not again asked to mention the highest percentages to be expected. Had I been, I should most gladly have answered the question, for it would have given me an opportunity of illustrating the high standards of drug purity which British chemists and druggists accept—in this matter of resin of scammony the United States' Pharmacopœia requiring "at least 75 per cent.," the French Pharmacopœia "75 to 80 per cent.," Pereira, "75 to 80 per cent," *the British Pharmacopœia* "80 *to* 90 *per cent.*"

Mr. Brown says that "Dr. Attfield obtained *what he called* 76 per cent. of resin, and from a perfectly dry powder 80 per cent." I obtained what *was* 76 and 80 per cent. of resin. This doubly licensed gentleman has not the slightest warrant for thus casting a doubt on my practical chemistry.

Mr. Brown asks how the scammony could be said to be up to the highest standard of the British Pharmacopœia. Nobody has said it was. He asks why was 80 and not 90 given? Beautiful simplicity! He admits that the scammony was "a fair sample," nay, adds that it was "a good sample." Wherefore, then, the fuss he makes. He states that his object in writing is to show that the standard of the British Pharmacopœia is not too high for pure scammony. By the way, he does not show this; but he might have written a letter or a paper on that subject, without trying to impugn my accuracy—either of quotation or manipulation.

Mr. Brown conjectures that the prosecution might not have broken down as it did if the Pharmacopœia had been forthcoming. Mr. Brown's liberty to indulge in conjecture is incontestable; but if he will again read the opening of the case and the final decision, he will see that neither the official standard nor the proportion of resin in the scammony had anything whatever to do with the issue. The defendant was summoned for selling scammony powder adulterated with flour and chalk, and the magistrate's decision was that although a little flour and chalk were present, the scammony was not adulterated.

Mr. Brown, besides giving way to conjecture, regrets the trial, is sorry for me, hopes that the magistrate will, in future, suspect chemical witnesses and only be satisfied with the Pharmacopœia; and winds up with some advice to Mr. Piesse. I cannot sympathize with Mr. Brown's regrets, sorrows, or hopes, or even with his conjectures; and as to his advice, must leave it to Mr. Piesse to accept, reject, or wholly disregard.

If Mr. Brown thinks himself strong enough to take up the broad question of the position of science, and especially chemistry and pharmacy, in our courts of law, let him send a paper to the approaching meeting of the British Pharmaceutical Conference. I will gladly propose him as a member of that body; and if his essay includes the idea that professional experts, medical as well as chemical, should be witnesses on neither side, but judges' assessors, I and other will give him our strongest support.

John Attfield.

S. Lyons.—Your letter and enclosure have been forwarded to the publisher.

E. George.—Tomes's 'System of Dental Surgery,' published by J. and A. Churchill.

A. P. S.—(1) Several papers upon the subject have appeared in former volumes of this journal, and a *résumé* of them, with references, was published in vol. i. of the present series, pp. 421 and 481. (2) If it is not labelled "poison" it certainly ought to be labelled, that it should not be given to a child excepting under medical advice.

C. Biddiscomb.—Your letter has been handed to the Secretary. See the notice on p. 31.

T. H. Fletcher.—It may be prepared by passing an excess of sulphurous acid through milk of lime.

"*Excelsior.*"—You are mistaken; the communication appears on p. 928 of the last volume. All communications for the Editor should be sent to the Journal Department, 17, Bloomsbury Square.

C. D.—Probably syrup of iron and quinine is meant, five grains in a drachm.

Communications, Letters etc., have been received from Mr. Young, Mr. Deighton, Mr. Hanbury, Mr. Rimmington, Messrs. Langton, Edden, and Hicks, Mr. Hickson, Mr. Strickland, Mr. Darby, Mr. Creig, J.T.R.

SCAMMONY AND ITS ADULTERATION.

BY A. F. HASELDEN, F.L.S.

Authors have stated that chalk, starch, gum, common resin, guaiacum, jalap resin, decoction of jalap, and of the leaves and twigs or villous stems of the scammony plant, senna, manna, gamboge, and ivory black, are used for the purpose of adulterating scammony.

The following form for making spurious scammony has been published as being followed by some dealers:

Gum Scammony	6 pounds.
Gum Arabic	6 pounds.
Calomel	2 ounces.
Aleppo Scammony	1 pound.
Ivory Black and Water . . .	q. s.

This was printed and published forty years ago, yet not so far back but that some may remember having seen it. Whatever may have been the case then, I do not believe for one moment that any such system is now followed,—unless it be in an article I have before me and obtained recently, yclept *skillet*, valued at 13*s*. per lb., and so named I infer from the pot in which it was melted and mixed together. Of the use to which this is put I am quite ignorant.

I have never yet found common resin, guaiacum, or jalap resin in scammony; at the present time obviously, jalap resin would not be used, as it is dearer than scammony resin. Common resin and guaiacum are readily found if present. That there are several qualities of scammony or scammonium of the B. P. in the market, and I presume in use, there can be no question. I have before me five wholesale price lists, wherein I see Aleppo scammony quoted from 18*s*. to 38*s*. per lb., and virgin scammony from 34*s*. to 40*s*. and 44*s*. per lb. This variation may be readily understood, as one buyer may purchase under more favourable circumstances, or such an article may vary in quality without fault of any one, and thus fetch a less price. In one instance out of the five lists, scammonium B. P. is quoted at 60*s*. per lb.; this must be something exceptional. Resin of scammony does not vary much in price, being quoted from 13*s*. to 16*s*. per lb. I have some which cost me 30*s*., but the manufacturers of this article will, I believe, discontinue making it, as it possesses intrinsically no advantage over the cheaper; the difference in the cost, I am led to think, arises from the employment of pure spirit in one case, and methylated in the other, and though the spirit would be recovered, there must be some lost. These resins may be readily examined by burning, and I found the quantity of residue precisely similar in both, amounting to less than 5 per cent. of ash.

I would now venture to suggest where, perhaps, the framers of the Pharmacopœia compounds in which scammony is employed seem to have acted inconsistently. In the London Pharmacopœias, before the publication of the B. P., virgin scammony was invariably ordered. In 1864, a permission or discretion was placed in the hands of the compounder, in making extract. colocynth. co., to use either scammony *or* resin of scammony; in 1867, B. P., *resin* of scammony alone is ordered, leaving no option, whilst in pilul. colocynth comp., of both books, scammony, meaning virgin scammony, is required. It may be worth while to inquire why this apparent confliction; that which seems good for the extract might be thought good for the pill, the confection, and the compound powder. I will now refer to the opinions expressed years ago, when the resin of scammony was introduced by Messrs. McAndrew. In vol. xviii., page 452, 1st series PHARM. JOURN., Dr. Fred. J. Farre is stated to have reported at the evening meeting of the Society, Feb. 3rd, 1859, as follows:—"The principal cases therefore are Nos. 1 and 3; in these I think the resin and virgin scammony acted about equally well. In the first case both purged effectually and quickly, the virgin scammony rather the most; each griped upon one occasion, and not upon the other. In the third case the resin purged the most, but it also griped the most. As far, therefore, as I can judge from these few trials (five cases), I am of opinion that the medicinal value of the two preparations is about equal." Dr. Johnson reported also well of the resin. Upon the same occasion Dr. A. B. Garrod spoke favourably of it, as thus:—

"From these numerous observations, 120 in number, together with many others which have not been tabulated, I am quite convinced that the scammony by the new process from the untapped root is quite equal as a remedy to the very best virgin scammony met with in commerce, and equal in fact to the resin which is extracted from commercial scammony by means of ether, and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and therefore being perfectly uniform in its physical characters, composition, and therapeutic action. There can therefore be no objection, but manifest advantage, in employing it in place of the scammony commonly met with."

In the same volume, p. 548, I find myself writing favourably of the new resin, and after fifteen years I see no reason to alter that opinion. After these quotations I feel that I may safely suggest that, in the next edition of the B. P., resin of scammony may be introduced in the place of scammonium, and in describing the mode of obtaining scammonium, if retained, instead of saying "a gum-resin obtained by *incision* from the living root," it would give more correct information if stated by cutting the living root *through* at the top, about two inches from the neck, below where the stalks spring from.

I come now to the consideration of the employment of the resin from another point of view. A genuine article may be readily obtained at a moderate price, and it may be easily examined; but, so long as the authorities require virgin scammony to be used, I would recommend that the best that can possibly be obtained be bought, and this practice alone would soon stop the admixtures abroad, which I cannot but think arise from want of care on the part of the collectors, the mode in which it is collected, and the temptation there is to make weight.

Let me impress upon those who may have any doubt upon the subject that the substitution of the cheap scammony for the scammonium of the B. P. in the preparations contained in that book, or where scammony is ordered by prescribers, is virtually an adulteration. The B. P. states that from 80 to 90 per cent. of resin may be extracted by ether, but it would be unreasonable to expect that every pound in a chest taken out separately would yield that percentage, and therefore some margin should be allowed in the examination of such a substance before it is condemned as being adulterated.

PRESUMED HYBRID BETWEEN CINCHONA CALISAYA AND C. SUCCIRUBRA.

We have been favoured with the following extract of a letter from Dr. de Vrij to Mr. J. E. Howard, dated July 6th, 1874 :—

"I have read with much interest your paper on the presumed hybrid between *C. Calisaya* and *C. Pahudiana*, particularly the fact observed by you that this hybrid, *grown out of the tropics*, contains quinamine. Till now, this alkaloid has only been found, both by Dr. Hesse and by me, in the red bark grown in British Sikkim, which is situated out of the tropics. * * * *

"Although I have great confidence in the chemical skill of Mr. Moens, my experience about the constituents of the Java Calisaya and Pahudiana barks compels me to draw a conclusion quite opposite to that made by him. In the numerous specimens of Java *Pahudiana* bark analysed by me, I invariably found them to contain chiefly cinchonidine with little quinine and cinchonine, and *never quinidine;* whilst in the Java Calisaya bark I very often found quinidine, this alkaloid sometimes even preponderating. (PHARM. JOURN., June and July, 1864.) It seems, therefore, to me that the grafting has made a change in the constituents of the bark."

Mr. J. E. Howard remarks upon the foregoing, "It is fortunate that the strongest confirmation is thus given to the views of Mr. Moens, since by a transposition, for which I alone am responsible, 'the latter' should read 'the Calisayas,' and 'the former' 'the Pahudianas.' This error of mine thus brings out the truth more clearly.—J. E. H.

THE APPENDICES OF THE BRITISH PHARMACOPŒIA.

BY WALTER G. SMITH, M.D. DUBLIN,

Fellow and Censor K. and Q. C. P. I.; Examiner in Materia Medica, Q. U. I.; Assistant Physician to the Adelaide Hospital.

(*Concluded from page* 23.)

VOLUMETRIC SOLUTION OF NITRATE OF SILVER.—$AgNO_3 = 170$.—1000 grain-measures contain $\frac{1}{10}$ molecule $= 17$ grs.

Uses.—This solution is used in the quantitative estimation of three substances, viz., hydrocyanic acid, arseniate of sodium, and bromide of potassium, but may be applied likewise to the estimation of chlorides and iodides. It is also employed officially in the detection of fousel oil or aldehyd in spirit of wine. (See *Spiritus Rectificatus.*)

The fundamental reactions upon which the processes depend are—

I. (*a.*) $HCy + NaHO = NaCy + H_2O$.
   (*b.*) $2\,NaCy + AgNO_3 = (AgCy,NaCy) + NaNO_3$.
   (*c.*) $(AgCy,NaCy) + AgNO_3 = 2\,AgCy + NaNO_3$.
II. $KBr + AgNO_3 = AgBr + KNO_3$.
III. $Na_2HAsO_4 + NaHO + 3\,AgNO_3 = Ag_3AsO_4 + 3\,NaNO_3 + H_2O$.

Procedure.—For hydrocyanic acid (Liebig's method).—Add excess of liquor sodæ to the acid (*a*), and drop in the silver solution until a *permanent* precipitate of cyanide of silver begins to form. The reason that no permanent precipitate forms at first, although cyanide of silver is insoluble, is this. So long as any free cyanide of sodium remains in the solution a *soluble double cyanide* of silver and sodium is formed, by equation (*b*), but so soon as all the cyanogen is thus combined, the next drop of nitrate of silver in excess decomposes this double salt, and a permanent precipitate of cyanide of silver is formed by equation (*c*). Now the molecular weight of $HCy = 27$, but since 1 molecule $AgNO_3 = 2$ molecules NaCy, see equation (*b*), *i.e.*, 2 molecules HCy (or $27 \times 2 = 54$), $\frac{1}{10}$ molecule $AgNO_3 = \frac{1}{20}$ $HCy = 2{\cdot}7$ grs.

For any given case, then, we have $1000 : n :: 2{\cdot}7 : x$.

For bromide of potassium. Dissolve in water and add the standard silver solution until, after agitation of the liquid and subsidence of the precipitate, a drop of the test-solution ceases to cause further precipitation. The molecular weight of $KBr = 119$, therefore since 1 molecule nitrate of silver $= 1$ molecule bromide of potassium, $\frac{1}{10}$ $AgNO_3 = \frac{1}{10}$ $KBr = 11{\cdot}9$ grs.

For arseniate of sodium. Expel the water of crystallization by heating to 300° F., so as to obtain a definite anhydrous salt (Na_2HAsO_4), convert into neutral arseniate by adding a little of the vol. sol. of soda, and then run in the silver solution until after agitation of the liquid and subsidence of the precipitate, a drop of the test-solution ceases to cause further precipitation. The molecular weight of $Na_2HAsO_4 = 186$, therefore since three molecules of nitrate of silver $= 1$ molecule arseniate of sodium, $\frac{1}{10}$ $AgNO_3 = \frac{1}{30} Na_2HAsO_4 = 6{\cdot}2$ grs.

In testing the following substances

Acidum Hydrocyanicum	270 grs.	=	1000	grain-measures.
Potassii Bromidum	10 „	=	840	„ „
Sodæ Arsenias (dry)	10 „	=	1613	„ „

VOLUMETRIC SOLUTION OF OXALIC ACID. $H_2C_2O_4\,2H_2O = 126$.—1000 grain-measures contain half molecule $= 63$ grs.

Use. This solution is used in the Pharmacopœia only for the estimation of bases (alkalimetry), principally salts of potassium, sodium, and ammonium. Because oxalic acid is dibasic, and the bases to be determined by it are mostly monobasic or univalent, it is more convenient to take *half* the molecule of oxalic acid in the standard volume of 1000 grain-measures.

NOTE.—Oxalic acid is also employed in volumetric analysis for standardizing solutions of permanganate of potassium :—

$$2KMnO_4 + 5H_2C_2O_4 + 3H_2SO_4 = K_2SO_4 + 2MnSO_4 + 8H_2O + 10CO_2.$$

Weigh the substances before and after the operation; the loss of weight $= CO_2$ expelled, and $5CO_2 =$ molecule $KMnO_4$.

Procedure.—Add a little litmus to a weighed quantity of the basic substance, diluted or dissolved, and run in the standard acid from the burette cautiously until the last drop turns the liquid red.

The fundamental reaction of this process is typified by the following equation :—

$$2NaHO + H_2C_2O_4 = Na_2C_2O_4 + 2H_2O.$$

That is, 1000 grain-measures of the acid (containing $\frac{1}{2}$ molecule) will neutralize one molecule of any monobasic substance or half molecule of a dibasic substance. For example, it is stated in the Pharmacopœia that one ounce of Liquor Potassæ ($= 462{\cdot}9$ grs.) requires for neutralization 482 grain-measures of the standard acid, and that this corresponds to 5·84 per cent. The molecular weight of KHO is 56, then,

$$1000 : 482 :: 56 : x = 26{\cdot}9 = 5{\cdot}84 \text{ per cent.}$$

Carbonic acid turns litmus purple, and therefore in testing alkaline carbonates the standard acid solution is allowed to drop in until the well-stirred liquid assumes a purple tint (due to the liberated carbonic acid); the liquid is then *gently* warmed to promote the escape of the carbonic acid gas, and more acid run in until the last drop of acid turns the solution red.

In testing compounds of lead and lime the indicator consists in the cessation of the formation of a precipitate, because the oxalates of lead and calcium are insoluble.

The caustic alkalies and their carbonates are never met with in commerce in a state of absolute purity, and usually contain from 90 to 98 per cent. of the pure compound.

The tartrates of potassium, citrate of potassium, and Rochelle salt are estimated volumetrically by first converting them into their respective carbonates by ignition, and then adding standard acid. One molecule of neutral tartrate of potassium, and two molecules of acid tartrate of potassium yield one molecule of carbonate of potassium when burnt; and two molecules of Rochelle salt (tartrate of potassium and sodium) yield one molecule of carbonate of potassium and one molecule of carbonate of sodium. Under the same circumstances, two molecules of citrate of potassium yield three molecules of carbonate of potassium.

The following substances are tested with the vol. sol. of oxalic acid.

Ammoniæ Carb.	59	grs. =	1000	grain-measures.	
Borax	191	„ =	1000	„	„
Liq. Ammon. .	85	„ =	500	„	„
„ „ Fort.	52·3	„ =	1000	„	„
„ Calcis . .	4380	„ =	200	„	„
„ „ Sacch.	460·2	„ =	254	„	„
„ Plumbi Subacet.	413·3	„ =	810	„	„
„ Potassæ .	462·9	„ =	482	„	„
„ „ Efferv.	4380	„ =	150	„	„
„ Sodæ . .	458	„ =	470	„	„
„ „ Efferv.	4380	„ =	178	„	„
Plumbi Acetas .	38	„ =	200	„	„
Potassa Caustica	56	„ =	900	„	„ If pure = 1000
Potassæ Bicarb.	50	„ =	500	„	„
„ Carb. . .	83	„ =	980	„	„
„ Citras .	102	„ =	1000	„	„
„ Tartras .	113	„ =	1000	„	„
„ „ Acida	188	„ =	1000	„	„
Soda Caustica .	40	„ =	900	„	„ If pure = 1000
„ Tartarata	141	„ =	1000	„	„
Sodæ Bicarb. .	84	„ =	1000	„	„
„ Carb. . .	143	„ =	960	„	„

VOLUMETRIC SOLUTION OF SODA. $NaHO=40$.—1000 grain-measures contain one molecule, *i.e.*, 40 grs.

Use.—This solution is used for the estimation of acids (acidimetry).

Procedure.—To a weighed quantity of the acid dissolved in water, or diluted if necessary, add some infusion of litmus, and cautiously run in the standard soda solution until the last drop turns the solution blue.

The fundamental reaction of this process is represented by the following equation:—

$$NaHO + HCl = NaCl + H_2O.$$

Therefore, 1000 grain-measures of the soda solution (containing one molecule soda) will neutralize one molecule of any monobasic acid (hydrochloric, nitric, or acetic); half molecule of any dibasic acid, *e.g.*, tartaric or sulphuric; and one-third molecule of any tribasic acid, *e.g.*, citric.

In delicate experiments turmeric may be used as the indicator instead of litmus, especially because some neutral salts, as acetates, citrates, and tartrates, exercise a slight alkaline action upon litmus.

Example.—Under Acid. Hydrochlor. Dil. it is stated that six fluid drachms require for neutralization 1000 grain-measures of the standard solution of soda, and that this corresponds to 10·58 per cent. The molecular weight of hydrochloric acid $=36·5$, therefore the 1000 grain-measures of soda solution $=36·5$ grains of HCl. But the six fluid drachms of the dilute acid weigh 345 grains, and so we have—

$$345 : 100 :: 36·5 : x = 10·58 \text{ per cent.}$$

This solution is used in testing the following substances:—

Acetum	445·4	grs. =	402	grain-measures.	
Acidum Acet. . . .	182	„ =	1000	„	„
„ „ Dil. . .	440	„ =	313	„	„
„ „ Glac. .	60	„ =	990	„	„
„ Citricum . .	70	„ =	1000	„	„
„ Hydrochlor. .	114·8	„ =	1000	„	„
„ „ Dil.	345	„ =	1000	„	„
„ Nitricum . .	90	„ =	1000	„	„
„ „ Dil.	361·3	„ =	1000	„	„
„ Nitro-hydr. Dil.	352·4	„ =	920	„	„
„ Sulphuricum. .	50·6	„ =	1000	„	„
„ „ Arom.	304·2	„ =	830	„	„
„ „ Dil. .	359	„ =	1000	„	„
„ Tartaricum .	75	„ =	1000	„	„

NOTE ON A REACTION OF GALLIC ACID.*

BY HENRY R. PROCTER, F.C.S.

If a solution of sodic or potassic arsenate, of faintly alkaline reaction, be added to one containing gallic acid, and the mixture exposed to the air, it will rapidly absorb oxygen, and develope an intense green colour. If the liquid be undisturbed, the change will commence at the surface, and a beautiful green layer will be formed, floating on the colourless liquid; while if air be altogether excluded, no apparent change takes place. 0·05 mgr. of gallic acid will produce a decided colouration in 1 c.c. of water. The arsenical solution must not be acid, but excess of alkali causes irregular oxidation and the formation of brown products.

Dilute acids change the green to a clear purplish red, and cautious neutralization with alkalies restores the green, but any considerable excess of the latter destroys the colour. In its reactions with acids and alkalies it shows a certain similarity to the colouring matter of red cabbage, but in most other reactions the two are completely dissimilar. There is also a considerable difference in their absorption-spectra, the cabbage green transmitting a broad band of red, while the gallic green does not.

Concentrated nitric and sulphuric, and boiling hydrochloric acids change the colour to a pale yellow, which is not restored by ammonia, but, in the case of nitric acid, is changed to a deep orange-brown.

Oxidizing agents mostly change the colour to an orange-brown. Even iodine in potassic iodide does this immediately.

The colour is also destroyed by reducing agents. *Sulphuretted hydrogen* passed into the acid solution rapidly decolorizes it, with no immediate precipitation of arsenic sulphide, and but slight deposition of sulphur. *Ammonic* and *sodic sulphides* instantly change the colour to brown or orange. *Sulphurous acid* and *ammonic sulphite* destroy the colour in either acid or alkaline solution.

Sodic hyposulphite does not completely destroy the green, but makes it paler, and on the addition of hydrochloric acid a pale bluish green remains, which is unaltered by excess of acid, but gradually fades away.

Nascent hydrogen from zinc or sodium amalgam rapidly decolorizes the acid solution, but only acts very slowly on the alkaline one. No arsenetted hydrogen is evolved. The green matter is not taken up from its aqueous solution by ether, bisulphide of carbon, benzene, or aniline, but is partly precipitated by alcohol.

* *Journal of the Chemical Society for June*, 1874.

When gallic acid is present in excess, a green solution is sometimes formed, which is not reddened by acids, but only turned purplish, and which, on standing, deposits a bluish precipitate.

The reaction seems peculiar to gallic acid. Gallotannic acid slowly gives a faint greenish tint, probably due to traces of gallic acid, while pyrogallin not only does not give the reaction, but seems to interfere with it when gallic acid is present.

THE MUTUAL RELATIONS OF DRUGGISTS AND PHYSICIANS.

The following is taken from an Address upon the Mutual Relations between Prescribers and Dispensers, delivered by Dr. Charles E. Buckingham, before the Graduating Class of the Massachusetts College of Pharmacy, April 22, 1874 :—

It is now some thirty years since I began the practice of medicine. About that time, I remember seeing an advertisement in a Boston newspaper :—"For sale. An apothecary's stand and fixtures." And, among the inducement to purchase, was the statement that "it requires no previous acquaintance with the business." This was in the city of Boston, where we should find people boasting that things were done more by rule than elsewhere in the country. Thirty years ago it would have been considered a difficult matter to find a carpenter, a cooper, a shoemaker, or any other mechanic in charge of a piece of work in his own trade, who had not passed through the regular stages of an apprenticeship for seven years, and of a journeyman. No man would have been looked upon as a safe legal adviser who had not been trained in the whole mystery of the law ; and he who had not at the least read his Bible, would have been considered a blind leader of the blind, had he undertaken to instruct us or our fathers in the mysteries of theology, or to explain the doctrines of sin and salvation, erroneous as the notions of either speaker or hearer might have been.

At the same time, he or she who professed to be born with curative powers, was sure of having a limited number of followers. In former days, a certain amount of mystery was supposed to be necessary in the treatment of disease. Education was not always considered a necessity; that is to say, what we call education to-day. Certain men were supposed, by the world at large, to have been born with the power to heal diseases, and others to have acquired that power by their prayers. Indeed, this belief has by no means departed; and there are enough of the weak-minded still left to encourage the hypocrite and blasphemer who prays for a living, and who advertises to the world that he is about to pray. Such weakness is more common in country communities, although in this city the medical practitioner not infrequently falls in with those who believe that the seventh son of a seventh son has miraculous powers. There are still those who believe in incantations, and night after night, and week after week, the believers in spiritual manifestations consult the medium, whose whole work consists in prescribing the last new remedy for consumption, or in repeating the age of the grandmother, or the number of dead brothers, which the applicant has forgotten that he told her only ten minutes before.

Within a few years, another form of quackery has come into being, believed in by many, though not in any degree by those who practise it. You understand, of course, that I speak of that class of practitioners who pretend to believe that the more you reduce the strength of a medicine, the more you increase and develope its powers ; and that a millionth of a grain has more power than a grain. The men who pretend to act upon this system—I do not know of one who does more than pretend—are aided in their sham by the progress made by chemists in analysing drugs and discovering ultimate principles, which these fellows use under names which do not belong to them. The ignorant public does not and cannot know that the two per cent. of quinia extracted from "Jesuit's bark," or the ten per cent. of morphia extracted from the opium, is not an evidence of the progress of a so-called school of medical practice, which is not followed, even by those who profess it.

But there is progress; progress in your profession, progress in mine. And that progress will be more marked in the next fifty years than it has been in the last fifty. When it was first proposed that druggists should employ only those as assistants who were educated, or to be in part educated, outside of the particular shop in which they were employed, the proposition was laughed at by a large number of those who now believe it to be the true course. But how stands the record? Not a druggist, or pharmaceutist if you like the word better, of really good standing, but is anxious that his boy should have a better education than he had, and that they should require their successors to be still better educated. And if you, young gentlemen, are in earnest in acquiring knowledge, and determined to follow properly the course which has been marked out for you here, and which really you have only begun upon, the day is not far distant when every drug store and its laboratory will be a successful field of scientific business, as some few now are; and the fancy goods store combined with the liquor saloon, as some few have been in years past, will take a lower position or be blotted out.

The same incredulity about its success was manifested when the Medical Department of Harvard University proposed to do away with the peculiar style of instruction which had always been followed there and in all other schools about the country. The substitution of a more thorough course of medical education was pronounced impossible; students would not attend upon it; and this more surely, because a verbal examination of ninety minutes at the end of the course was to be displaced by a written examination at the end of each year, and which might be protracted to twenty-seven hours in all. Those of us who were determined to succeed, and have succeeded to a certain extent, are in full accord with the gentlemen who stand at the head of your college.

It seems impossible that men were admitted to the degree of doctor of medicine, all over this country, with a single examination in nine branches, allowing ten minutes to each examination. That, however, was the fact. And we were warned that if we made the change proposed, the Medical School of Harvard University was destined to die, and its days were already numbered. But there were those who believed that an attempt should be made at progress, and that if death was to be the result, why, it could not be in a better cause.

What has been the result? The examinations have been spread over the three years. Twenty-seven hours have taken the place of the ninety minutes. The number of our students, in the four months' course of 1870-71, was three hundred and one. In the nine months of the following year, this number was greatly reduced. Fifty-four only had adopted our new plan. In the year 1872-73 this number increased to ninety-three, and in the first term of this year we could count one hundred and eighteen students who were willing to undergo the severe examinations required for a degree. But how about expenses and income? for the former must have largely increased and the latter must have diminished. Why, gentlemen, the income of this year, which has but little more than *half* gone, has already been nearly a third more than it was in the whole of last year.

What has become of the other students? Why, they have preferred to go where examinations are easier; where the time is shorter; where the drill is less severe. We are satisfied that the change in the manner of study will be a success. The course which we have marked out is in parallel with the course which has been marked out for you, in taking you from the counter of the drug store, and giving you extra work and study in the college laboratory. We have more branches of study, and our course is longer and harder. Let each and all of us do what lies in our power to make both colleges successful. The quack pretender, perhaps, can make money more rapidly and more abundantly than the educated pharmaceutist or physician. If pecuniary compensation is all that a man seeks, it is true that he can acquire it more easily in quackery and humbug than in fair and open work. That is a matter of taste. A thief or a forger can conquer both in that game. That is a matter of taste also. I am aware that, in your profession, there are obstacles to be overcome which many others have not to contend with. It is true that the laws of the land have put taxes upon your sales perfectly unwarranted, and that many of these are so worded that even the most honest man cannot act under them without risk of punishment and disgrace. People complain of the cost of the medicines which you furnish, and yet do nothing in any way to aid you in getting rid of burdensome per-centages laid upon the same article, over and over again. A stir in the moiety business within a few weeks past is, I trust, the beginning of a reformation by which those government sneak-thieves will be got rid of, who spend their time in trying to trap honest pharmaceutists into breaking a law which, to appearance, was blindly worded purposely.

The duty of educating a doctor of medicine is not completed when he has pocketed his diploma. Indeed, he has then only learned how to learn. He may answer correctly all questions, but his practical education is to begin at that point, and will only be finished with his life or on his retirement from the profession. The duty of this college is to produce such a class of educated graduates as will be able to manufacture and inspect drugs for themselves. But your duty, gentlemen, was not completed when you passed the examination which entitled you to your diplomas. You may say that your course of study is practical throughout. No more so than ours. The older you grow in your work, the better it should be in every way, and science should go hand in hand with profit.

"The experienced doctor," so called, is, in many places, one who has grown grey in the practice of his profession without ever learning a fact which he did not read as an undergraduated student. And he who is often considered by the ignorant public to be the reliable druggist is no better. The object of both our schools is to teach the beginner how to teach himself afterwards.

There are relations between our professions which it is worth while to call attention to. It has been the case, sometimes, that the pharmaceutist and the physician have run in opposition to each other. This should not be. Every man has his preference for individual members of any trade and of any profession with which he has dealings. But you have no right to turn my patients into the hands of any other medical man who chooses to send his prescriptions to you. I have no right to require my patients to buy drugs at any other store than that which they are accustomed to deal at, because he who keeps it is one who patronizes me. The physician who keeps a private remedy at a particular shop, which can be put up only on his order, and which no other druggist can understand, is a quack who has violated his word of honour. If you furnish drugs which I know to be inferior, because they cost you less than drugs of the first quality, that alters the case. Meanness is criminal wherever it exists, and should be punished.

Let us have a case or two from either side of the sheet. A medical man wrote a prescription for some morphia in pills. The size of the pills was excessive, and nothing upon the prescription indicated that there was any unusual call for what to most people would have been a fatally poisonous dose. There were no written directions, as there should be upon every prescription. The druggist very kindly said to the bearer of the prescription that he would prepare the medicine and send it to the house. He tried for several hours to find the writer, and at last caught him at the dinner table, was kept waiting for a time, and was finally informed by the doctor that he never made mistakes, and that the prescription meant what it said. Of course, the druggist returned to his shop, and while engaged in preparing the pills, a messenger from the same patient came with another prescription. It seems that, without waiting to see his office patients, the doctor, on finding that he had made a blunder, too proud to acknowledge it and thank his informer for saving his patient, had hurried to the patient's bedside, changed his prescription as the result of new thought, received the thanks of the family for his attention, and repaid the apothecary with meanness, for an act of kindness which prevented a coroner's jury.

I was knowing to the fact that a physician once advised some medicine to be thrown away because it did not come from A's shop, at which he traded, and no one in Boston knew so well as A how to prepare it. It had been purchased at B's shop. I also knew that B made all of that particular preparation which A sold. The bottle was refilled from the same fountain, and pronounced to be all right. The first was a case of meanness. Meanness and ignorance combined formed the second, and both of them were deserving of punishment. I have known the same physician to change the form of a prescription, given on emergency by another who had been called in his place, simply that none but himself should have the credit of giving relief.

I care nothing who the physician may be, nor who the druggist. The physician has no right to interfere, except upon stronger ground than mere acquaintance or personal preference, or even family connection. Least of all has he the right to decry the druggist's medicine, unless he has good reason to believe it to be of inferior quality. You know, and the public should know, how much medicines vary in quality, and that the price and quality go together. It will be no credit to any of you, if you sell medicine at retail for less money than your neighbour buys it for at wholesale. Take some of the common articles which families keep on hand, and see the difference in cost: sugar of lead from fifteen to fifty cents a pound; sweet spirits of nitre from twenty-five to seventy cents; powdered rhubarb from twenty cents to two dollars; Hoffmann's anodyne from thirty cents to one dollar and seventy-five cents; arrowroot from ten to fifty cents; and other articles used solely in prescriptions at equally varying prices.

(*To be continued.*)

THE ABSORPTION OF AMMONIA FROM THE AIR BY PLANTS.

BY T. SCHLOESING.

It is generally admitted that ammonia diffused in the atmosphere may be absorbed directly by the leaves of plants, and serve them as nitrogenous aliment. But as the author was not aware that this assimilation of aerial ammonia had been demonstrated experimentally, he made it the subject of a series of observations, the results of which he has reported to the French Academy of Sciences.*

The experiment consisted in the cultivation of two plants of the same species under parallel conditions, with the sole difference that one developed its foliage in an atmosphere supplied with ammoniacal vapours, the other in an atmosphere deprived of those vapours. In order to measure and regulate the ammonia supplied to the aerial organs, it was necessary to enclose the plant in a limited atmosphere renewable and perfectly separated from the soil. This latter precaution was indispensable in order to avoid all chance of absorption of the ammonia by the roots. The tobacco plant was chosen, because its straight

* *Comptes Rendus*, vol. lxxviii., p. 1700.

close stem facilitated the carrying out of the conditions of the experiment.

The vessels in which the plants were enclosed had a capacity of 250 litres, and the atmospheres were continually renewed at the rate of about 1200 litres of air in twenty-four hours; this air contained about one per cent. of carbonic acid. As it was found difficult to introduce the ammonia continuously in a gaseous state, the bottom of one of the vessels was covered with a weak solution of sesquicarbonate of ammonia, which was renewed daily. By determining the strength and volume of each quantity of solution that was introduced or removed, all the elements were obtained for calculating the total amount of ammonia diffused in the atmosphere of the vessel. The strength of the solution found to be most suitable was 0·900 gram of sesquicarbonate to the litre of water.

The experiment commenced on the 31st July, and was continued until the 14th September. The amount of ammonia volatilized in the atmosphere of apparatus No. 1 during that time was 1·327 grams, equal to 1·093 grams of nitrogen. The volume of air passed into the vessel being 45×1200 litres, or 54 cubic metres, each cubic metre would contain an average of 25 milligrams of ammonia, or in round numbers $\frac{2}{100000}$ of ammonia to one part of air.

The leaves, buds, stem and roots of each plant were collected separately, dried, and weighed. The nitrogen was estimated by combustion of the organic matter. The parts of No. 1 (supplied with ammoniacal nourishment) weighed 146·9 grams; those of No. 2, 139 grams. Three grams of No. 1 yielded 66·44 milligrams of nitrogen, or 2·22 per cent.; three grams of No. 2 yielded 53·13 milligrams of nitrogen, or 1·77 per cent. No. 1 attained the normal proportion of nitrogen which a plant of that species acquires in the natural conditions of vegetation; No. 2 was sensibly below that standard. The nitrogenous alimentation of the latter had been wanting, whilst the former had sufficiently supplied. According to the analysis,—

The 146·9 grams of	No. 1	contained	3·260	nitrogen.
The 139·0	,, No. 2	,,	2·460	,,
	Difference		0·800	,,

Attributing this excess of nitrogen to the gaseous ammonia supplied to No. 1, it would appear that of the 1·093 grams of nitrogen furnished during the whole time of the experiment the plant had assimilated 0·800 gram, or about three-fourths.

The absorbed ammonia, as might be supposed, went to form organic compounds, and in fact it was not found upon analysis either in the alkaline state or as nitric acid. It was interesting therefore to note whether the absorption of ammonia by the leaves had any effect upon the production of nicotine. It was found, however, that the leaves of No. 1 contained 1·87 per cent. of nicotine, and those of No. 2, 1·78 per cent., so that it would appear that it had no such influence. The nitrogenous compounds derived from the assimilated nitrogen were diffused throughout the entire plant. The leaves, stem, and roots of No. 1 were all more rich in nitrogen than the corresponding parts of No. 2, so that the enrichment of the leaves had profited the stem and the root.

These results agree generally with those obtained in the experiments by Adolf Mayer, which were recently referred to in this Journal (vol. iv., p. 778).

A UNITED STATES AND BRITISH INTERNATIONAL PHARMACOPŒIA.*

BY PROFESSOR CHARLES HERMON THOMAS, M.D.

There is something more than a sentimental relation suggested by the fact of our speaking the same tongue as the British nation. To the physician and pharmacist this is a matter of every-day recognition. The professional text-books and journals of both countries, devoted to medical science, are used in common in their colleges and public and private libraries, and in all departments but one—and that confessedly of prime practical importance—the terms used by authors convey a precise and identical meaning; while in that of materia medica, including pharmacy, the proper English and Latinized names employed are permitted to convey different meanings when used in the two countries, notwithstanding the liability to fatal mistakes added to the confusion thus engendered. If the same disparity of definitions of technical terms had existed in chemistry, anatomy, surgery, gynæcology, etc., that is found in materia medica, arising, as it does, out of the different proportions of constituent materials used in the medicinal preparations, common by name—but by name only—to both the United States and British Pharmacopœias, there never would have arisen that constant useful interchange of thought and experience which now exists; and if it were possible to introduce such a disparity in the ideas conveyed by like words into other departments of scientific literature as exists in this, it would undoubtedly prove a barrier to communication scarcely less formidable than a total difference in tongue or race.

The British and Foreign Medico-Chirurgical Review for January, 1874, contains an article on the U. S. Pharmacopœia, which, while giving us credit for introducing certain improvements, such as the class of glycerites, closes with the following suggestive paragraph:—

"There is almost a constant departure from the directions given in the British Pharmacopœia, in the matter of proportion of ingredients used; so that whilst many tinctures and infusions are considerably stronger than ours, there are many weaker. Thus, for example, the infusions of calumba, cascarilla, and senna are made only of half strength, whilst those of digitalis and gentian are considerably stronger, the former being of double strength.

"Likewise in the matter of tinctures, we find the tinctures of aconite, belladonna, nux vomica, and cantharides made double strength, while those of cannabis, of hyoscyamus, of digitalis, and of colchicum are one-fourth weaker. Lastly, tincture of opium and the camphorated tincture are made weaker than the British preparations.*

* From the *American Journal of Pharmacy* for July.

* The relation in the strength of these preparations is not correctly given by the *British and Foreign Medico-Chirurgical Review*; the difference in the officinal weights and measures has evidently not been taken into account. On close examination it will be found that the preparations of the two Pharmacopœias agree much better than the above quotation would lead us to believe; in fact, the majority, we believe, are *practically* identical in strength, like tincture of digitalis, hyoscyamus, etc.

It must be remembered that 30 fluid ounces of British Pharmacopœia are equal to 29 fluid ounces of U. S. Pharmacopœia, the difference being only about $1\frac{1}{2}$ fluidrachms, and that the British ounce weighs 42·5 grains less than the U. S. troy ounce. One fluid ounce (imperial and U. S. measure) of the above-mentioned preparations contains of the active drug the following number of troy grains:—

	Brit. Pharm.	U. S. Pharm. In fld. oz. imperial.	U. S. Pharm. In fld. oz. wine measure.
Infusum Calumbæ . .	21·87	14·5	15
,, Cascarillæ .	43·75	29	30
,, Digitalis . .	3	7·25	7·5
,, Sennæ . . .	43·75	29	30
Tinctura Aconiti Rad.	54·7	174	180
,, Belladonnæ .	21·87	58	60
,, Cannabis . .	21·87	21·75	22·5
,, Cantharidis .	5·47	14	15
,, Colchici . . .	54·7	58	60
,, Digitalis . .	54·7	58	60
,, Hyoscyami .	54·7	58	60
,, Nucis Vomicæ	43·75	116	120
,, Opii	32·8	36·25	37·5
,, Opii Camphorata	2	1·813	1·875

—Editor *American Journal of Pharmacy*.

"It may be that the Americans are justified, at all events in some cases, in not following our authorities in this matter of strength of preparations; but at the same time it is a matter of regret that greater uniformity in this matter, between two nations speaking the same tongue and so intimately bound together by social and commercial ties, does not prevail.

"To British medical men cast abroad in America, and to American physicians landed in England, it must be vexatious, and at times a cause of injury to patients, to find that well-known formulæ, common by name to both, differ widely in their doses and activity on one and on the other side of the Atlantic.

"Speaking generally, these variations unhappily affect the more potent remedies rather than the others.

"The notion of an International Pharmacopœia has been broached, and has many recommendations, although we apprehend the more or less divergent medical opinions afloat in different countries, and still more, circumstances dictated by peculiarities in modes of life, in climates and in floras, will lead each nation to claim more or fewer special drugs, and so destroy absolute uniformity.

"On the other hand, there would be a sufficient array of substances and formulæ admitting of so much concurrence as in some measure to attain the object desired. But, however this may be, there is good reason for bringing the British and United States Pharmacopœias more in accord, and so far making the first move towards an international codex, and we should be pleased to hear of communications being opened between the Committee for the British and the Convention for the United States' Pharmacopœia in anticipation of so desirable and object."

No teacher who has endeavoured to instruct a class in medicine or pharmacy composed of students representing both nations will fail to realize the difficulty—not to say impossibility—attendant upon the labour of attempting to define and fix upon their minds the ever varying strength and dosage of such important officinals as the reviewer has here cited.

And no physician who has read the standard British authors on therapeutics, practice, diseases of women and children, and the like, with a view to making their precepts available in the treatment of disease, will dissent from the assertion that the value of such works is seriously impaired and sometimes entirely destroyed by the same fact.

The subject is one of far too great importance, and the defect too grave in its actual and possible consequences, to be allowed to remain longer unrecognised; and there can be no doubt that the suggestion at the close of the above quotation will find hearty approbation and cooperation wherever the question is presented.

Probably the chief obstacle to a universal Pharmacopœia, for all civilized nations at least, will be found in the diverse systems of weights and measures employed in different countries; but there are indications that the general interest in and acceptance of the new chemistry, with the adherence of its writers to the metrical system, will serve as an easy introduction for the essential agreement necessary for a satisfactory means of intercourse.

And probably, also, the use of the metrical system will have to become more familiar to scientific men at large than it is at present, before universal communication will be seriously attempted in this direction. But this question aside for the present, we are on a footing for establishing at once a unity of standard for the composition of the principal preparations of the Pharmacopœias of the English-speaking people, and this notwithstanding the radical differences between the systems of weights and measures in Great Britain and in the United States respectively.

The expedient needed to be adopted is no other than for the United States and British pharmacopœial authorities to unite in putting into force the rule established by the Scandinavian nations at their International Convention held in 1865, when the Pharmacopœias of Norway, Sweden, and Denmark were unified, and which rule is to express the relative quantities used in pharmacy in proportional parts by weight, as, *e.g.*, two parts by any system of weight of the first ingredient, four of the second and one of the third, etc., thus securing like relative proportions in all standard compounds.

At the U. S. Pharmacopœial Convention, which met at Washington in 1870, the following resolution of like import was ordered to be taken as a basis for the last decennial revision of our Pharmacopœia; but, for some reason never satisfactorily made known, the Committee on Revision appears to have disregarded its plain provisions:—

"*Resolved*, that measures of capacity be abandoned in the Pharmacopœia and that quantities in all formulas be expressed both in *weights* and in *parts by weight*."

The consolidation already effected of the London, Dublin, and Edinburgh in the British Pharmacopœia, the several Pharmacopœias of Central Europe constituting the German Empire, and some others, all tend to assure the practicability, as well as to suggest the advisability, of the step here proposed.

The advantages to be obtained by an international adjustment of at least the two Pharmacopœias in question, so that a given name shall indicate a preparation identical in composition and strength in both countries, are obviously many and important; the objections to such a change few and insignificant.

A NEW ALKALOID FROM MORPHINE.*

BY G. NADLER.

The author, by the action of ammoniacal solution of oxide of copper on morphine, has obtained an alkaloid, the chlorine compound of which is dazzling white, sparingly soluble in cold, but easily soluble in hot water, and insoluble in alcohol and ether. The aqueous solution gives with ammonia a dense, white, amorphous precipitate, which does not alter in the air while moist, but dries up, like aluminium hydrate. Ferric chloride produces in the aqueous solution an amethyst-red colour, which rapidly darkens. Strong sulphuric acid dissolves the alkaloid on warming, forming a dark-green solution, which does not alter when heated sufficiently to volatilize the acid. Blue ammoniacal copper solution assumes a splendid green colour. Potash, like ammonia, produces in the aqueous solution a curdy precipitate, which, however, dissolves in excess in the cold. In this respect the alkaloid resembles morphine. The potash solution, when heated to boiling, deposits the alkaloid in silvery scales. The alkaloid rapidly reduces silver nitrate, and gives with platinic chloride a pale-yellow platinum salt. Dilute sulphuric acid throws down from the solution in hydrochloric acid a white amorphous sulphate. The new alkaloid is distinguished from morphine by being precipitated in the amorphous state by ammonia, by its behaviour with ferric chloride, ammoniacal copper solution, potash, and strong sulphuric acid, and by the sparing solubility of its sulphate; and from apomorphine by the fact that in the moist state it does not become coloured on exposure to the air, but remains perfectly unaltered.

CEYLON PRODUCTS.

In a description of Ceylon contained in the report of British Colonies at the Vienna Exhibition, prepared at the request of the British Commission, we find brief allusion to certain products of that Island which are of interest to the chemist and druggist. With regard to cinchona, we note that its cultivation in Ceylon was commenced about ten or eleven years ago. A number of young plants, carefully selected, were imported and set in the Botanical Gardens at Hakgala, at an elevation of about 6000 feet. The results, as an experiment, have been most satisfactory. The trees have already yielded a small supply of bark, which is said to have been valued in England at an exceedingly high rate. A large number

* *Chem. Centr.* 1873, 675; from the *Jour. Chem. Soc.*

of crossed species have been spontaneously developed, which, it is believed, will produce exceptionally fine bark. The coffee planters, too, have largely availed themselves of the gratuitous issue of young plants from the Government plantation, and have placed them in those positions on their estates which are unsuited for the growth of coffee. Sufficient success has been attained to justify sanguine hopes that an extended cultivation will be profitable, and that a large export business will spring up. The cultivation of vanilla does not appear to be very extensive, and no record can be found of the amount grown in or exported from the colony. An excellent sample was sent to the Vienna Exhibition. Cinnamon is now exclusively and profitably grown mainly in the neighbourhood of Colombo, and is described as having somewhat the appearance, and being about the size, of the European laurel. Of late years, owing to the immense improvement in the preparation and cultivation of the spice, and to a largely increased demand at remunerative rates, there has been a much increased export from Ceylon, and there has been considerable progress in the industry. The plant exhales no perfume, but the bruised leaf or bark has a powerful odour of the spice. By means of careful pruning the plant can be made to grow the twigs or their branches free from knots, which yield what is called the pipe-cinnamon, possessing a higher marketable value than sheet bark, which is peeled from the stem. The exportation of plumbago from Ceylon has also much increased during the past few years, and this is owing to the extensive European demand for crucibles. Crucibles made of plumbago are said to have much greater power of resisting the high temperature employed in smelting than any other yet constructed. The raw material is found principally in underlying quartz in the south and south-west of Ceylon, and is worked by the natives under licences from Government. It is largely used in the preparation of what is called black-lead for polishing purposes; while a more recent application of it, and probably the most useful, is as a lubricant.

EXPERIMENTS ON THE IMPORTANCE OF THE INORGANIC CONSTITUENTS OF FOOD.*

BY J. FORSTER.

The author observes that the experiments of Chossat and A. Milne-Edwards seem to show that animals cannot grow without a supply of salts. He criticizes the experiments of Magendie, Wundt, Klein and Verson, Kemmerich, and others, on the effects of a deficiency of salts on adult animals. Some of these with washed fibrin show that albuminous substances can be digested even though no salts are given. In some of the experiments, the result was not due to want of salts, but to want of albumen. The salts in the body may be divided into two classes—1st, those which are firmly combined with combustible substances in the body, and are indispensable ingredients of the juices and blood; 2nd, those which are simply dissolved in the juices. These latter greatly exceed the first class in amount, and consist of those salts which are introduced into the body, or are liberated by the decomposition or oxidation of combustible substances in the organism. Those of the first class cannot leave the organism so long as they remain in combination in organized structures, and even when they are simply dissolved in the juices the arrangements in the kidneys hinder their exit from the body. This is proved by the experiments of Bidder and Schmidt, which show that chlorine quickly disappears from the urine when chlorides are withheld, although it is still abundant in the body; by those of Voit and Bischoff, which show that nitrogen and phosphoric acid rise and fall in the excretions when flesh is put on or lost from the body; and those of Kemmerich, which show that when potash and earthy salts are given, but soda withheld, the soda in the blood continues normal, the potash only being excreted. The author's experiments, made by feeding pigeons and large dogs with albumen, starch, fat, and water without salts, showed that the animal organism, though kept in equilibrium as regards the supply of other nutriment, requires for its support a supply of certain salts, and if this supply is defective or entirely absent, the body loses salts and is thereby destroyed. When the mineral constituents are removed as much as possible from the food of an adult animal, the processes of tissue change, destruction, and decomposition in the body proceed until the death of the animal, in the same way as when the food contains inorganic constituents. Gradually, however, derangements occur in the functions of various organs, which finally hinder the conversion of nutriment into absorbable modifications, and thus prevent the reparation of the combustible materials of the body. On the other hand, by arresting some of the processes necessary for life, they occasion the destruction of the organism before the impossibility of absorbing nourishment could produce decline and death.

The excretion of inorganic substances, though much diminished, continues during the whole time that salts are withheld. It is least at the very time that the supply of combustible material is most abundant, as then the tissues of the body are protected from decomposition, and the salts they contain are retained. Although the salts of the body are to a great extent retained and used over and over again, yet a certain proportion of them is excreted, and when salts are withheld and other food given, the consequences are, 1st, that the whole body, and especially the parts in which destruction goes on actively, such as blood and muscle, become gradually poorer in salts and richer in albumen; 2nd, that although the total quantity in the body is lessened, the mixture of salts in organized structures and in the juices remains unaltered. The diminution of salts in the muscles causes muscular exhaustion, and in the nerves causes first excitability and then paralysis of the nerve centres. The quantity of salts necessary in the food is less than has hitherto been supposed, but further experiments are required to determine its exact amount.

THE INFLUENCE OF HEAT ON PREPARATIONS OF SARSAPARILLA.*

BY J. F. JUDGE, CINCINNATI, OHIO.

For the purpose of answering the query, whether sarsaparilla is altered in its sensible properties and injured in its medicinal qualities by the heat of a water or steam-bath, proposed by the American Pharmaceutical Association, I prepared a fluid extract by exhausting a good article of sarsaparilla with a mixture of alcohol 92 per cent., five (5) parts, and of water three (3) parts.

One (1) fluid ounce of this was evaporated to a thick pilular extract over a water-bath, yielding sixty-three (63) grains of extract of a brownish colour, and retaining the peculiar taste of the fluid extract.

Upon digesting this extract with two (2) fluid ounces of a menstruum similar to that used originally in making the fluid extract, nearly all was dissolved, there being left but little insoluble matter; hence I conclude that in sensible properties sarsaparilla is not injured by the "heat of a water or steam-bath."

In regard to the second branch of the query I cannot say much. From the fact that little if any change occurs in sensible properties, we would be inclined to conclude that the medicinal are likewise uninjured. The direct establishment of that point scarcely comes within the practical work of a pharmacist. Then, again, there is much diversity of opinion in regard to the actual medicinal value of the crude drug itself. It is my opinion, based upon the experiments above cited, that sarsaparilla is not altered in its sensible properties nor injured in its medicinal qualities by the heat of a water or steam-bath.

THE CONFERENCE MEETING.

The departure from established usage which this year marks the proceedings of the British Pharmaceutical Conference will probably occasion more than ordinary difficulty in the work of those who have to organize the various arrangements for the meeting. Notwithstanding the fact that London is so large and its resources so great in comparison with those of the provincial towns in which the Conference has been accustomed to meet, there can be no doubt that there is also a vast difference as regards the facility with which those resources may be made available in the two cases. The meeting of such a body as the Conference in a provincial town is an affair of sufficient importance to make almost everything for the time being subservient to it. The entire resources of a town are for the moment placed at the disposal of the hosts and their visitors, and the ordinary business of the place is transacted meanwhile as it best may be in a corner. This could not well be the case in the metropolis, and hence it is not without some degree of anxiety that the question as to the successful issue of the approaching meeting is to be regarded.

In speaking of the possible success of this meeting, we do not intend to suggest any apprehension that there will not be a numerous atendance, or any doubt as to the value and interest of the proceedings being at least equal to what they have been on other occasions, but rather to indicate that in consequence of the peculiar circumstances of London it will be especially necessary to have some knowledge beforehand of the number that will be present at the meeting.

Only last year a similar experiment was made in London by the British Medical Association, and the most unfortunate thing connected with it was the overwhelming success of the meeting in regard to numbers, the visitors having been so far in excess of the most sanguine anticipations that, coming suddenly and unexpectedly, there was no possibility of providing for all. Such a result is probably one of the most vexatious forms of failure, and it is in order to guard against any repetition of such an unfortunate circumstance that we desire to call the attention of our readers to the requirements of the case.

It is satisfactory to find that these requirements have not been lost sight of by the Secretaries, and we have much pleasure in complimenting them on the admirable manner in which they have provided for obtaining the information they are in need of. For the information of those who are not members of the Conference, we may state that in the circular lately sent out to make known the order of proceedings during the meeting, it is stated that those who purpose attending either the conversazione given by the Pharmaceutical Society, the Conference dinner, or the excursion to which our provincial friends are invited, should communicate their intentions to the Secretaries. In order to facilitate this, a series of printed forms are sent with the circular, referring respectively to the several features of the meeting, as well as to the provision of hotel accommodation. By merely signing these forms and sending them to the Secretaries, all difficulties arising from uncertainty as to the number of guests to be provided for will be easily removed, and we trust that a request so reasonable as well as so especially necessary in the present instance will be generally responded to as early as possible by those who intend to be present at the meeting.

The time fixed as the latest for sending in these notifications is the 27th of this month, leaving just ten days before the meeting commences for the Secretaries to carry out their final arrangements. We understand that many have already availed themselves of the means provided for communicating their intention to attend the conversazione, dinner, and excursion, and in the course of the ensuing week we trust that all who contemplate taking part in the metropolitan meeting of the Conference will do the same.

THE IRISH PHARMACY QUESTION.

The Select Committee on the Apothecaries' Licences Bill has met twice during the present week, the sitting on Monday being devoted to the examination of Mr. G. W. Sandford, Mr. John Mackay, and Sir Dominic Corrigan; that on Thursday to the examination of Dr. Rawdon Macnamara.

Mr. Sandford, speaking with the experience of twenty years' service on the Council of the Pharmaceutical Society of Great Britain, during seven years of which he held the office of President, expressed his opinion that the Society would be willing to undertake the duties which would be imposed upon it by the extension of the provisions of the Pharmacy Act, 1868, to Ireland; and he did not think any insuperable difficulty would occur. Such an arrangement he considered would be advantageous to Ireland, and would conduce to uniformity of pharmaceutical qualifications in the two islands, whilst the establishment of another Society would probably lead to confusion, as it would be necessary that the titles granted by such a Society should differ from those given by the British Society. Mr. Sandford described the constitution of the Board of Examiners in Scotland and the identity of the examinations, and explained that the members of the Society residing in Scotland enjoyed rights the same in every respect as those of the English members. The topic of counter-prescribing was again raised, and Mr. SANDFORD said the practice had always been discouraged by the Society. Dr. BRADY having asked whether, as the Medical Council is the "fountain" of the Pharmacopœia, that body ought not to have some control over examinations in which the Pharmacopœia played so important a part, Mr. SANDFORD said that the Medical Council had always been desirous that the duty should be entrusted to the Pharmaceutical Society alone.

Mr. JOHN MACKAY, as Honorary Secretary to the North British Branch of the Pharmaceutical Society of Great Britain, said that the plan of having one Society for England, Scotland, and Wales had worked exceedingly well, and he thought it might well be extended to Ireland. He described the business of the Branch as being conducted by a committee chosen annually by the Scotch members, the recommendations being forwarded to the Council in London,—upon which Scotland was at present represented by two members. He said there had never been any difficulty; they had always been told to ask for whatever they wanted, and their expenses had always been allowed. The Society had a library and a museum in Edinburgh, and they had been able to make favourable arrangements for the attendance of students upon the lectures delivered by the University professors. He further said that the examiners for Scotland were nominated by the North British Branch, and resided in different parts of Scotland; the appointments being made by the Council meeting in London, and subject to the approval of the Privy Council. Mr. MACKAY said he thought the present chemists and druggists in Ireland ought to pass a modified examination before being placed upon the Register, although the chemists and druggists in business in England before August, 1868, had been admitted without one; because in England they represented the class who had previously been engaged in the dispensing of medicines, whilst in Ireland they are mere vendors of drugs, and are not now allowed to dispense. If a body of pharmacists were provided for Ireland, he would advise the apothecaries to stick as closely as possible to medical practice, and leave the sale of drugs and dispensing of medicines to the class specially educated for that purpose.

Sir DOMINIC CORRIGAN agreed with the preamble of the Bill as to the inconvenience existing through the absence of dispensers from some parts of Ireland, and he instanced the Saltbridge Union, a district containing 18,000 inhabitants, where formerly there was an apothecary in every town, but where now it was not possible to get a prescription dispensed. Sir DOMINIC CORRIGAN, however, thought it desirable to establish a separate Pharmaceutical Society in Dublin, having power to enact bye-laws regulating the examinations, subject to the approval of the Lord-Lieutenant of Ireland, and enjoying reciprocal rights with the British Society. His objection to the extension of the operations of the existing Society to Ireland appeared to be based upon a belief that examiners would be sent over from England, whilst the fees from Ireland would be devoted to defraying an extravagant expenditure upon objects from which Ireland would reap no benefit. Among the items of expenditure specially selected for condemnation were the expenses of the conversazione and journal, the fees of the examiners, the house expenses, and the salaries of the secretaries and clerks. When reminded by the Chairman that the members in Scotland did not appear to feel aggrieved, Sir DOMINIC said that this was probably because the subject had not attracted their notice, but that he thought now he had called attention to it they would be dissatisfied. He objected to all the portions of the Apothecaries' Hall scheme which would give that body any control over a new Society, but said he thought a good nucleus for such a Society would be found in the licentiate apothecaries. Sir DOMINIC said he would confine the legislation to the creation of a class for the dispensing and compounding of medicines, and he would not interfere with chemists and druggists, or with the Poisons Act for Ireland, which allows any person to vend poisons, subject to regulations similar to those of the Pharmacy Act, 1868, as to labelling and registration of sale. Being pressed upon this latter point, Sir DOMINIC said that he could give no other answer than that this Act had met with the general approval of the public and of coroners, and should not be disturbed. So far as this is a matter of opinion, of course Sir DOMINIC may be right; but, as a matter of fact, an Irish coroner has expressed himself in very strong terms respecting the policy of the Act.*

Dr. MACNAMARA showed a general unacquaintance with the details of existing and proposed legislation on the subject. He was ready to express an opinion upon the Apothecaries' scheme, "so far as he was acquainted with the details;" the last of the three clauses of Mr. ERRINGTON'S short Bill, respecting which he was supposed to give evidence, he was unacquainted with; and the Pharmacy Act, 1868, which the Bill proposed to extend to Ireland, he had never read. It may be presumed therefore that the decided opinions he expressed upon the subject were evolved from his inner consciousness. He said that he approved of the Bill so far as it went, but that it was faulty, in that it did not provide for the establishment of a Pharmaceutical Society in Dublin. The extension of the existing Society to Ireland would, in his opinion, paralyse pharmaceutical science in that country, since the appointments of Presidents, Vice-Presidents, Members of Council, Professors, Examiners, etc., would always be confined to the "head-quarters" in London, and there would be no stimulus to Irish pharmacists. This opinion was not affected

* See vol. iv., p. 16.

by the reading of Mr. Mackay's evidence respecting the North British Branch, and Dr. Macnamara said he could not conceive that courses of lectures delivered mainly for medical students could be made available for pharmaceutical students. As to the probable financial position of a new Society, Dr. Macnamara thought it would be self-supporting; but he had not considered whether the examination fees would require to be supplemented by annual subscriptions from the members. He admitted that a fund would be required to start the new Society, and being, as he expressed it, "put into a corner" to say where this money was to come from, replied that, as the object would be *pro bono publico*, he thought a grant might be made from the public funds. Dr. Macnamara agreed with Sir Dominic Corrigan, that a suitable nucleus for the proposed Society might be chosen from the licentiate apothecaries, and also in objecting to a mercantile body like the Apothecaries' Hall having any control over a scientific society. He considered that it was essential there should be reciprocity between the two Societies in Great Britain and Ireland, and, upon the syllabus of the Minor examination being shown to him, said that it appeared to be a satisfactory test to enforce before admitting a person to the right of dispensing physicians' prescriptions.

After Dr. Macnamara's opinions had been placed upon record, strangers were requested to withdraw, and the Committee proceeded to the consideration of its report.

THE JURIES BILL AND THE ADULTERATION ACT.

Chemists and druggists who have been looking forward to the passing of the Juries Bill to place them in the same position with pharmaceutical chemists in respect to exemption from jury service, will regret to learn that there is little probability of the measure becoming law during the present Session. On Tuesday night, in replying to a question in the House of Commons, Mr. Lopes said that having regard to the late period of the Session, and the amount of business which remained to be got through, he had no hope of passing the Bill this Session. But he added that he felt sure, considering the principles of it had been sanctioned by the House, the public would not be satisfied until some such measure had been enacted.

It would appear also that, notwithstanding the prompt report of the Select Committee on the Adulteration Act, there is no prospect of early legislation to carry into effect its recommendations. Mr. Sclater-Booth, the President of the Local Government Board, said on Monday evening that it would be impossible for him to make any proposal on a matter of so much difficulty and interest in the limited time now available before the prorogation of Parliament.

Proceedings of Scientific Societies.

TENNESSEE PHARMACEUTICAL ASSOCIATION.

At the second annual meeting of the Tennessee Pharmaceutical Association, the President, Mr. Wharton, delivered the following annual address:—

If any one of you, my fellow members of the Tennessee Pharmaceutical Association, has ever had occasion, as I now have, to make a pharmaceutical speech, or read a pharmaceutical essay, you can bear sympathetic testimony as to the difficulties to be met in attempting to select a suitable theme, and still further in setting it forth in an attractive style.

Practical pharmacy, as a topic, is not prolific in ideal abstractions or poetic fancies. It opens to us no broad and boundless field of elocution, and supplies us with but little food that may be dispensed as oratorical dainties; but it is gratifying to know that in the multitudinous details of our every-day experience we often meet with much to entertain and instruct us. Which one of us, in reviewing his days of apprenticeship, cannot recall some mischievous use of hartshorn that delighted him at somebody's expense? or who has not a more vivid recollection of somebody's delight at his expense? Has any one of us failed to play the trick with chlorate of potassa and sulphur, and have all of us failed to shiver into fragments mortars, pill tiles, and various other breakables in the neighbourhood of such a charge as overdid the work a trifle? Who has not been tested or tested some one else with incompatible prescriptions that would make liquids of solids and solids of liquids? But taking a stride beyond these, do we not come to a period of thoughtfulness, when we begin truly to realize that our occupation or profession is not so easily grasped and mastered as at first it seemed; yet, withal, it is still more attractive. We see it expanded and spread out as a sea, fed and sustained by many streams. It is embraced in the network of the sciences, and is part and parcel of the same. With one arm it lays hold on geography, and we have drawn in to us a host of acquaintances from every department of physical nature. Here are minerals, vegetables, and also animals from various countries. Europe, Asia, Africa, small islands and great continents, have on our shelves or in our drawers their representatives. Torrid, temperate, and frigid zones, fields and forests, oceans, rivers, plains, mountains, volcanoes, and even meteors, possibly from other worlds, unite their products in our stores.

With another arm our profession lays hold on chemistry, and who can detail the wonders and beauties that are here unfolded? Almost daily we hear or read of new discoveries in this domain of science, impressing us with the conviction that its boundaries are unknown and its depths unfathomed.

With another arm we are connected with the science of numbers, and learn to calculate the nice adjustment of compounds, to weigh invisible substances, and measure imponderable forces.

To make a general statement: Pharmacy is now or has been in the course of its development connected in some way, more or less obvious, with almost every science and art. Astronomy, or astrology, in former times, appeared almost at the foundation. Alchemy nurtured it. Geology, mineralogy, meteorology, zoology, botany, horticulture, agriculture, floriculture, all combine to make up this system, and man, in search for curative agents, has seemingly tried everything visible and invisible that ingenuity could apply. He has made tributaries of all knowledge and all speculations, of all trades and occupations. He has studied "physic" and physics, mechanics, natural, mental, and moral philosophies, and everything else that holds out a shadow of hope as to the discovery of the "elixir of life." Hence a well-informed pharmacist should be a man of varied knowledge and versatile talents. He should comprehend the elementary principles of many sciences, the rudiments of many arts. He should somewhat embody the qualifications of many trades and professions, be able to use himself mentally and physically, and to do "whatsoever his hand findeth to do." He should possess energy, patience, and courage to overcome difficulties, to acquire competent knowledge and information, without which he must prove a disgrace to himself, a dishonour to his profession, and a dangerous man to the public. He should also strive for such originality as will enable him to improve himself and his fellows, and advance the character of his calling. If he is thus faithful to his duties he cannot be idle nor indolent, and must exert a useful influence in his community. May it not be said that in no respect does it stand more prominently forward than in its philanthropic attitude, as the science of healing the sick and alleviating human sufferings? How careful, then, should we be that our preparations are well made with good materials; and when elegance of appearance and pleasantness of taste may be combined with efficient remedies, should we not prefer to have them so? To this end we should, as a united association, and as individual members of the same, take some pains to inform ourselves and each other in every one of its many branches. Should we not read, reflect, and experiment, in order to improve, and wherever we can suggest a genuine advantage in working out a published formula, should we not do so for the benefit of all? It is often the case that a little thing is worth knowing, and a great thing needs simplifying. Are we not familiar with some processes that are cumbrous and difficult that might be made easy and expeditious by the application of thought and skilful experiment? Let us endeavour to add something to the stock of knowledge already attained, and strive to be of some use "in our day and generation." We must be vigilant, lest at some inadvertent moment we do some careless act that will destroy life instead of imparting health. Let us always feel less of an inflated dignity than of serious responsibility. Moreover, let us take no undue advantages of our patrons, but charge reasonable prices, since in most cases they are wholly ignorant of the value of what we render them, and trust us to deal fairly with them. Let us scorn bribery and "percentages," and stand or fall on our merits, with a consciousness of having endeavoured to discharge our duties to our fellow-men. May it never be said of us that we desire epidemics and sickness in order to increase our sales of medicines. Let us prove that we no more thrive in seasons of calamity than do others. And now it may be appropriate to put in our plea as to the charge sometimes made against us, that we make our livelihood off of the necessities of others. We say, so does almost every honest dealer. The grocer, that sells flour for bread, does; the butcher, that sells meat, does. The merchant, the mechanic, the farmer, all make their living off of the necessities of the people, and why should it be a reproach to a pharmacist to do the same, unless he extorts from the suffering? Is not his labour as valuable as another's, and are not his earnings as honest as others? If he takes pay from a man that would die without *medicine*, does not the man that sells flour take pay from one that would die without *bread?*

In conclusion, I must tender to you my kindest regards, and express my sincere appreciation of the high compliment that I have received at your hands in the promotion to this office. I also offer my regrets at not having served more efficiently and actively during the term about to expire, and I hope that many anniversaries may dawn upon the Tennessee Pharmaceutical Association.

ROYAL INSTITUTION.

THE CHEMICAL CHANGES ACCOMPANYING THE SMELTING OF IRON IN BLAST FURNACES.*

BY DR. C. R. ALDER-WRIGHT, F.C.S.

Notwithstanding that the operation of iron-smelting is one dating from a very early epoch, and in spite of its magnitude at the present day, and the consequently numerous series of observations and experiments made thereon by various chemists, it is nevertheless true that until recently our knowledge of the chemical changes which occur during the process was extremely limited.

It will not be necessary for me now to enter into any detailed description of the apparatus and machinery now in use in this manufacture; the blast furnace, as most are aware, is virtually a gigantic vertical tube into the top end of which the materials used are continually inserted; these consist of the ore to be smelted, the fuel, and lime or limestone as a flux. At the lower end of the tube, air usually heated to 300°-500° is continually injected by a blowing engine through nozzles termed *tuyeres*, whereby the fuel is burnt and the necessary heat generated: the earthy materials of the ore and the lime of the flux unite, forming a fusible "slag," which is continually drawn off at the base, whilst the molten reduced iron accumulates below the slag, being specifically heavier, and is drawn off from time to time into moulds of sand, when it constitutes the pig-iron of commerce.

Ordinarily the air injected, or "blast," is previously heated by passing through tubes of iron or piles of brickwork, themselves heated by the combustion of the waste gases that escape from the furnace itself; to collect these, the top of the furnace is closed by a bell-shaped valve which serves for the introduction of materials when open, but which when closed compels the gases to issue through an orifice in the side of the furnace near the top, whence they are led away through pipes to the heating stoves, furnaces of boilers, etc.

The nature of the ore used necessarily exerts a great influence on the chemical changes that take place; the following table indicates the general composition of several of the chief descriptions of ore used. In some instances the iron exists naturally as ferric oxide; in other cases chiefly as ferrous carbonate.

	Hæmatite.	Magnetic Ore.	Spathic Ore.	Clay Ironstone.	Brown Ore.
Fe_2O_3 ...	90-100	30-70	0-3	0-3	40-70
FeO......	...	13-33	36-50	35-55	0-5
Al_2O_3 ..	0-2	0-5	0-2	1-7	1-7
CaO......	0-3	0-5	0-4	1-14	1-7
MgO ...	0-1	0-2	0-4	1-9	0-2
MnO ...	0-1	0-1	1-25	0-2	0-3
SiO_2 ...	0-10	0-10	0-5	2-17	1-35
CO_2......	0-1	0-10	37-42	22-37	0-5
P_2O_5 ...	0-1	0-2	trace	0-2	0-2
SO_3......	0-1	trace	,,	0-3	trace
H_2O ...	0-1	0-4	—	0-1	6-18
Essential Composition.	Fe_2O_3 with little or no earthy matter.	Fe_2O and FeO with earthy matters.	$FeCO_3$ and $MnCO_3$ crystalline.	$FeCO_3$ and much earthy matter.	Hydrated Fe_2O_3 and earthy matters.

When ferrous carbonate constitutes the ore used, the smelting process is usually facilitated by submitting it to a previous calcination in a kiln like a lime-kiln, whereby the ferrous carbonate becomes transformed into ferric oxide; when, however, the carbonate is not calcined before use, it speedily loses the carbon dioxide present therein, leaving behind an oxide of iron; this occurs in the top portion of the furnace, so that virtually the ores used may be regarded as consisting essentially of some form of iron oxide, with a varying amount of earthy matter of variable kind intermixed therewith.

The fuel used is ordinary coke or charcoal; when, however, raw coal is employed, it is completely coked in the top portion of the furnace, so that the fuel burnt at the tuyeres is invariably carbon.

As the blast enters the furnace it comes in contact with

* Lecture delivered at the Royal Institution of Great Britain, Friday, March 13th, 1874. Reprinted from the 'Proceedings.'

a mass of incandescent carbon, whereby its oxygen is firstly converted into carbon dioxide, and next into carbon oxide, the nitrogen for the most part remaining unchanged; not impossibly, a good deal of the carbon is burnt directly to carbon oxide, without passing through the intermediate stage of carbon dioxide; any moisture present in the blast is similarly converted into a mixture of carbon oxide and hydrogen; the amount of the latter necessarily varies with the hygrometric state of the atmosphere. Although hydrogen is a powerful reducing agent, the influence of the small quantity present in the blast furnace gases appears to be practically *nil*; the gases issuing at the top of the furnace contain on an average about as much free hydrogen as is brought in by the blast, whence it is evident that the hydrogen has contributed little or nothing to the reduction of the ferric oxide; and again, practical experience shows that the more moisture enters the furnace at the base, the more fuel is requisite to do the work, *i. e.* the development of hydrogen is injurious to the action rather than auxiliary.

What I shall have the honour of bringing before you to-night is the history of the changes that occur as the mixture of carbon oxide and nitrogen formed in the vicinity of the tuyeres rises through the furnace. This action has usually been described hitherto as a very simple one; the carbon oxide being viewed as simply removing the oxygen from the higher oxide of iron, forming successively a lower oxide and metal, carbon dioxide being evolved in accordance with equations (1) and (2), *infra.*

Table of Chemical Changes taking place in Different Parts of the Blast Furnace.

[A] Reduction of higher oxide to lower oxide and metal by gaseous carbon oxide:—

$$(1)\quad Fe_xO_y + CO = Fe_xO_{y-1} + CO_2$$
$$(2)\quad Fe_xO_y + yCO = xFe + yCO_2$$

[B] Oxidation of metal to lower oxide and higher oxide by carbon dioxide:—

$$(3)\quad xFe + yCO_2 = Fe_xO_y + yCO$$
$$(4)\quad Fe_xO_{y-1} + CO_2 = Fe_xO_y + CO$$

[C] Reduction of carbon oxide to carbon:—

$$(5)\quad xFe + yCO = Fe_xO_y + yC$$
$$(6)\quad Fe_xO_{y-1} + CO = Fe_xO_y + C$$

[D] Reaction of reduced carbon on iron oxide, forming carbon dioxide:—

$$(7)\quad 2Fe_xO_y + C = CO_2 + 2Fe_xO_{y-1}$$
$$(8)\quad 2Fe_xO_y + yC = yCO_2 + 2xFe$$

[E] Reaction of carbon dioxide on reduced carbon:—

$$(9)\quad CO_2 + C = 2CO$$

The changes that really take place are, however, much more complicated; it is true that those reactions do take place, but firstly carbon dioxide has a tendency to act on metallic iron, re-forming an oxide, and reproducing carbon oxide by reactions that are just the converse of (1) and (2), viz., in virtue of equations (3) and (4).

Nextly, metallic iron acts on carbon oxide, setting free carbon and forming successively a lower and a higher oxide in virtue of equations (5) and (6).

Again, the carbon deposited in virtue of reactions [C] reacts on the higher oxides of iron, producing lower oxides and metal, with evolution of carbon dioxide, in accordance with equations (7) and (8). And finally, carbon dioxide reacts on the deposited carbon, giving rise to the formation of two proportions of carbon oxide in virtue of equation (9).

Changes [A] and [D] may be referred to as *iron-reducing*, [B] and [C] as *iron-oxidizing*: changes [C] may be termed *carbon-reducing*, [D] and [E] *carbon-oxidizing*.

At any given point in the blast furnace all these chemical tendencies are at work simultaneously with more or less vigour according to circumstances; the action actually taking place at this point is, therefore, that due to the single resultant of all the multifarious forces at work; before, therefore, it is possible to enter into any explanation of the chemical changes occurring in the furnace itself, some knowledge must be gained of the relative magnitudes of these several forces. Considerable additions to our knowledge on these points have recently accrued, chiefly through the labours of I. Lowthian Bell, Esq., M.P., with whom I had the pleasure of co-operating in his researches.

As regards tendencies [A]. Although carbon oxide exerts no action on ferric oxide at ordinary temperatures, yet its influence is appreciable at temperatures far below the limit of the mercurial thermometer; the precise point at which the action commences varies with the physical condition of the ferric oxide; thus the following table illustrates this point.

Temperature at which Carbon Oxide begins to reduce Ferric Oxide.

Substance.	Minimum Temperature at which Carbon Dioxide is formed.	Temperature at which action is well marked.
Precipitated by ammonia ..	141°	149°
Calcination of ferric nitrate	145°	154°
Average calcined Cleveland ironstone	199°	210°
Ditto, more highly calcined	200°	206°
Calcination of ferrous sulphate	208°	216°
Pumice-stone soaked in ferrous sulphate solution and calcined...............	211°	227°

The fact that the action is perceptible at so low a temperature may be conveniently illustrated by passing a current of pure carbon oxide over precipitated ferric oxide in a flask heated to 150° in a paraffin bath, and passing the gases subsequently through baryta water, when the formation of a turbidity denotes the production of carbon dioxide.

It is noticeable that a specimen of ferric oxide that has been already slightly reduced in this way is first acted upon only at a higher temperature than that required in the first instance.

As regards equation (2) it may be remarked that it is impracticable to reduce *the whole* of any sample of iron oxide by means of gaseous carbon oxide at any temperature short of a white heat; in fact, metallic iron decomposes carbon oxide, becoming itself more or less oxidized at all temperatures below this in virtue of equation (5).

In reference to the converse changes [B], the oxidizing effect of carbon dioxide on iron is scarcely appreciable at a temperature of 300°, but is noticeable at 400° and upwards, being very considerable at about 600°: this may be illustrated by passing a current of carbon dioxide over fragments of metallic iron in a tube heated to a bright red heat, when much carbon oxide is evolved, so that the issuing gases may be inflamed.

The physical condition of the iron employed necessarily exerts a considerable influence on the rapidity of the reaction, the more finely divided the metal the more energetic being the action; thus pyrophoric iron is readily acted on by the air at the ordinary temperature, whilst more massive fragments of metal are unaffected under the same circumstances.

It is noteworthy that carbon dioxide is not capable of acting on all metals alike in this way. Copper, for instance, is unaffected at a red heat or upwards by carbon dioxide, whilst nickel and cobalt are oxidized with the production of carbon oxide, the change, however, taking place with less ease than with pure iron. The following table illustrates this point.

Comparative Action of Carbon Dioxide on Iron, Nickel, and Cobalt, at about 600°.

Iron	100
Cobalt	44
Nickel	11

Iron first begins to act	.	below 420°
Cobalt " "	.	about 550°
Nickel " "	.	above 550°

The consideration of the causes that lead to the possibility of the occurrence of the inverse reactions [A] and [B], and the different behaviour of iron and copper towards carbon dioxide, introduce us to some general principles in chemical dynamics. Whenever a body unites with oxygen, heat is evolved; thus the following table illustrates the quantity of heat produced by the union of 16 parts by weight of oxygen with various substances, the materials and products being all viewed as being examined at the constant temperature 500° C.

The numbers are calculated from the so-called "heats of combustion" of the bodies (at 15°) by means of the formula.

$$H_{500}=H_{15}+h_1+h_2-h_3,$$

where H_{500} = the heat of combustion at 500°.
H_{15} = " " at 15°.
h_1 = the heat required to raise the combustible from 15° to 500°.
h_2 = " " the oxygen through the same range.
h_3 = " " the product of combustion through the same range.

Combustible.	Product of Combustion.	Kilogramme heat units evolved at 500°.
Iron	Magnetic (and probably any other) oxide*	66·7
Carbon oxide	Carbon dioxide	68·8
Carbon	Carbon oxide	27·4
Carbon	Carbon dioxide	48·1
Hydrogen	Steam	58·9
Copper	Cuprous, Cupric oxide*	37·6

The evolution of heat during these actions may be exemplified by sprinkling iron filings into a large gas-blowpipe flame, when a brilliant shower of sparks is produced, heat and consequently light being developed by the oxidation of the iron. Similarly by burning carbon oxide at a jet through which a stream of oxygen can be forced, a blowpipe flame is produced equal in heating power to the oxyhydrogen flame, and like it capable of igniting lime, and thereby giving off a bright light, melting platinum, steel, etc., etc. Although carbon oxide actually gives out more heat than hydrogen in uniting with a given weight of oxygen (68·8 kilogramme units as against 58·9 when the action takes place at 500°), it is nevertheless much more difficult to obtain the same calorific effects from a carbon oxide-oxygen flame than from an oxyhydrogen flame. With a small flame, platinum may be readily fused and lime heated to intense brilliancy with either; but the latter gives a much more compact, and therefore hotter, flame when larger amounts of gas are used: the comparative slowness with which the carbon oxide oxidizes is illustrated by the circumstance that a jet of this gas issuing under some slight pressure from a narrow orifice will not continue to burn in the air, the flame as it were blowing itself out; whilst a jet of hydrogen or of coal-gas burns readily under the same circumstances.

It seems to be a general rule that no reaction of replacement coming under the general form

$$x+yz=y+xz$$

can take place if the reaction is attended with any considerable absorption of heat; *i. e.* the heat given out by the substances x and y, in uniting with the same weight of z, must either be approximately equal, or else that given out by x in uniting with z must be greater than that evolved by y in combining with z. Some few exceptions to this rule are known, notably reactions [D] and [E]: generally, however, the converse is the case, *i. e.* in reactions of this class there is usually an evolution of heat.

Now, copper and carbon oxide are not thermally equal as regards combination with oxygen; the latter evolves nearly double the heat given out by the former in uniting with a given weight of oxygen; hence the action of carbon oxide on copper oxide, producing metallic copper and carbon dioxide, must be attended with a large evolution of heat; thus at 500°:—

Heat produced by oxidation of carbon oxide to dioxide	+ 68·8
Heat absorbed during the reduction of copper oxide	− 37·6
Heat evolved	+ 31·2

Carbon oxide, therefore, reduces copper oxide to metal, forming carbon dioxide in accordance with the above rule; whilst the converse reaction, viz., oxidation of metallic copper by carbon dioxide and conversion of the latter into carbon oxide, does not take place, as it would be attended with a large absorption of heat, viz., 31·2 kilogramme units.

The evolution of heat during the reaction of carbon oxide on copper oxide, may be readily illustrated thus:—A tube filled with lumps of copper oxide is heated to a temperature short of visible redness, and a stream of carbon oxide is passed through it; the copper oxide immediately begins to glow brightly from the heat evolution that ensues during the reduction of the metallic oxide; on leading oxygen through the tube, when the reduction is over, and the mass has cooled down so as to be no longer visibly red hot, a still brighter glow is produced from the heat evolution during the reoxidation of the metal; the glowing is less bright in the first instance, for the threefold reason that there is somewhat less heat evolved (31·2 units as against 37·6), whilst the resulting carbon dioxide escapes while very hot, and consequently removes heat; again, it dilutes the carbon oxide, and makes its action less energetic.

In reference to the general rule just referred to, relating to the connection between the heat evolution on combination and the relative actions of bodies on one another, one particular case is noteworthy, of which reactions [A] and [B] afford a good example; if in a reaction of the form

$$x+yz=y+xz$$

there is little or no evolution of heat (*i.e.* if x and y both evolve approximately the same amount of heat in uniting with the same weight of z), it often happens that the converse reaction

$$y+xz=x+yz$$

may be brought about by modifying the circumstances, so that the following is the general rule for all cases as regards the equation

$$x+yz=y+xz$$

Case (1).—x evolves more heat in uniting with z than y does.

The reaction takes place under suitable conditions.

Case (2).—x and y evolve approximately the same amounts of heat in uniting with z.

The reaction may take place or its converse, according to circumstances.

Case (3).—x evolves considerably less heat than y in uniting with z.

The reaction (usually) does not take place, but the converse reaction frequently can occur under suitable conditions.

Thus in the case of reactions [A] and [B], there is but little heat evolution or absorption in either case.

---

* When a body forms more than one *solid* oxide corresponding to a class of stable well-defined salts, the heat produced for a given weight of oxygen consumed is identical with each oxide; this is not the case when *gaseous* oxides are formed as with carbon; nor even when solid oxides are formed when they do not correspond to classes of stable well-defined salts, *e.g.*, some of the oxides of manganese.

[A] Heat evolved by oxidation of carbon oxide to dioxide	+ 68·8
Heat absorbed by reduction of iron oxide	− 66·8
Heat evolved	+ 2·1

[B] Heat evolved by oxidation of iron . .	+ 66·7
Heat absorbed by reduction of carbon dioxide to oxide	− 68·8
Heat absorbed	− 2·1

In this respect reactions [A] and [B] may be compared with another well-known pair of inverse reactions, viz., the oxidation of iron by passing steam over it, hydrogen being evolved; and the reduction of iron oxide by passing hydrogen over it, steam being produced. In each of these cases, also, the thermal disturbance is not great, *i.e.*, hydrogen and iron are thermally approximately equal in reference to their combination with oxygen at 500°.

Steam and Iron.

Heat evolved by oxidation of iron	+ 66·7
Heat absorbed by reduction of steam . . .	− 58·9
Heat evolved	+ 7·8

Hydrogen and Iron Oxide.

Heat evolved by oxidation of hydrogen . .	+ 58·9
Heat absorbed by reduction of iron oxide .	− 66·7
Heat absorbed . . .	− 7·8

From the existence of the inverse reactions [A] and [B] it results that when a mixture of the two oxides of carbon acts either on metallic iron or on iron oxide, oxidation of the one or reduction of the other takes place until a definite relation exists between the iron and oxygen present in the resulting substance and the two oxides of carbon in the gaseous mixture; the composition of the inert substance necessarily varies with the temperature and the nature of the mixture of carbon oxides used; the higher the temperature and the more carbon dioxide is present, the larger is the amount of oxygen present in the inert substance. Thus Bell obtained the following numbers:—

CO_2 per 100 volumes of CO.	Temperature.	Oxygen in inert Oxide, $Fe_2O_3 = 100$.	Carbon deposited per 100 of Fe.
600	Red heat	90·0	nil
100	Bright red heat	67·5	"
47	Full red heat	8·2	"
11	Approaching whiteness	11·9	"
Nil (pure CO)	Bright red heat	1·0	0·3

Reactions [C]. The oxidation of carbon to carbon oxide evolves less heat than the conversion of iron into iron oxide; hence it might be inferred that iron will probably decompose carbon oxide with the evolution of heat, carbon being set free and an oxide of iron formed; thus thermally

Heat evolved by oxidation of iron . . .	+66.7
Heat absorbed by reduction of carbon oxide to carbon	− 27·4
Heat evolved . . .	+39·3

The circumstances attending this change have been studied at great length by Bell; at temperatures not higher than 200° it is possible to obtain small quantities of deposited carbon in virtue of these reactions; but the action is at a maximum at about 420°–450°; at higher temperatures but little carbon can be obtained in this way, owing to the carbon-removing influences [D] and [E]; a few tenths per cent. of carbon, however, are always deposited, the same result being arrived at whether metallic iron or ferric oxide be employed in the first instance. The oxygen communicated to the iron is for the most part removed again in virtue of reactions [A] and [D]; a minute quantity, however, is retained at all temperatures up to about 1000.° Since carbon is also present in the product, it might be supposed that the oxygen is present as occluded carbon oxide; that this is not the case, however, is shown by the circumstance that the whole of the carbon present is left behind in the free state on dissolving the impregnated iron in iodine water, or copper sulphate solution. Moreover the oxygen present is, under these circumstances, left behind in the form of an oxide of iron.

The process of acieration depends in the first instance on the occurrence of reactions [C]; carbon oxide is absorbed by the bars of iron, and is decomposed, particles of iron being deposited and iron oxide formed, this latter being immediately reduced again, either by carbon oxide (reactions [A]), or by acting on a part of the deposited carbon (reactions [D]); the blisters on blister steel are probably produced by the attempts at egress of the carbon dioxide thus produced.

When ferric oxide is exposed to the action of carbon oxide at about 420°, the time required to produce a given amount of carbon deposition varies greatly with the physical structure of the iron oxide, probably because this physical structure influences, as above described, the rate at which iron and lower oxides are formed in virtue of reactions [A]; thus the following table indicates the relative amounts of carbon deposited from various kinds of ferric oxide, by simultaneous exposure to the action of carbon oxide at 420°, for seven hours:—

	Carbon deposited per 100 of iron.
Calcined ferric nitrate	144·0
Precipitated by ammonia	95·4
Calcined ferrous sulphate	54·5
Pumice-stone soaked in ferrous sulphate and calcined	14·9
Calcined Cleveland ironstone . . .	0·3

After ten or twelve hours, however, the discrepancy is not so marked, as much carbon being then deposited with the Cleveland ore as is with the precipated oxide in seven hours.

The action of carbon oxide on certain other metals and their oxides has also been examined by Bell; the chief results arrived at are included in the following table:—

Comparative Action at 400°–500° of Carbon Oxides on various Metals and Oxides.

Higher oxides of iron, nickel, and cobalt;
  Reduced to lower oxides, and partially to metal; suboxides (Fe_2O, Ni_2O, and Co_2O) being formed, and much carbon deposited,

Spongy metallic iron, nickel, and cobalt;
  Partially oxidized, much free carbon being formed; iron most active, nickel least.

Higher oxides of manganese;
  Reduced only to monoxide (MnO); no free carbon being deposited.

Oxides of copper and lead;
  Reduced to metals; no free carbon deposited.

Oxides of zinc, chromium, and tin; metallic copper, lead, zinc, and tin;
  No effect.

In each one of these cases, where any action at all ensues it is uniformly of such a nature as to be included in the general rule above laid down; thus nickel and cobalt give out approximately as much heat in uniting with 16 grammes of oxygen as does iron, and therefore behave in analogous fashion, giving rise to converse reactions analogous to [A] and [B].

Reactions [D]. The occurrence of these reactions may be readily demonstrated by heating to redness an iron tube containing a mixture of carbon (as free as possible from hydrogen) and ferric oxide. As soon as the temperature rises to about 400°, carbon dioxide is evolved. The reaction, however, is complicated by the circumstance that the evolved carbon dioxide reacts on both the carbon present and the iron or lower oxides of iron formed by reactions [D], so as to give rise to the production of carbon oxide by reactions [E] and [A] respectively; hence as the action goes on, the amount of carbon dioxide in the mixture gradually lessens, and finally little but carbon oxide is evolved.

It appears exceedingly probable that the so-called "occluded carbon oxide" contained in malleable iron is really not occluded at all, but is produced in virtue of these reactions from a mixture of carbide and oxide of iron; as already stated, on exposing pure metallic iron to the action of pure carbon oxide at a bright red heat, a substance is obtained containing both carbon and oxygen, *not* in the form of occluded carbon oxide. On heating this product, in a Sprengel vacuum, a mixture of carbon dioxide and carbon oxide is evolved (the latter predominating greatly).

The whole process of "puddling" depends on the occurrence of reactions [D]; the carbon present in the iron (together with other impurities) is thus eliminated by the reaction on it of iron oxides formed in the puddling furnace by the action of the heated air.

Reactions [D] are thermally abnormal; although carbon displaces iron from its oxide, the reaction is attended not, as might be supposed, with an evolution of heat, but with a considerable absorption; thus at 500°,

Heat evolved by oxidation of carbon to carbon dioxide	+ 48·1
Heat absorbed by reduction of iron oxide	− 66·7
Heat absorbed . .	− 18·6

Reaction [E] is also abnormal, being attended with a still greater absorption of heat; thus at 500°,

Heat evolved by oxidation of carbon to carbon oxide	+ 27·4
Heat absorbed by reduction of carbon dioxide to carbon oxide	− 68·8
Heat absorbed . .	− 41·4

The physical structure of the carbon used has a considerable influence on the temperature at which both reactions [D] and [E] first take place; the lighter and more porous, the more readily is the carbon acted on; that deposited by reaction [C] is especially easily acted on; with ordinary charcoal or coke, reaction [E] does not appear to take place to any appreciable extent below 400°.

It is noteworthy that in some other cases besides reactions [D] and [E], where *solid* carbon is concerned, abnormal results are found to be produced; thus, by the action of carbon oxide on metallic zinc or tin, carbon should be set free even more readily than by iron, nickel, or cobalt, the oxidation-heat of each of the first two metals (per 16 grammes of oxygen) being greater than that of either of the latter three; in point of fact, however, no change at all ensues.

The gases of the blast furnace contain not merely carbon oxide and carbon dioxide, but also a large bulk of nitrogen; all experience, however, goes to prove that this acts solely as a diluent, and in no way interferes with the above-described reactions, saving in delaying them, *i.e.*, causing more time to be required for their performance; the presence of nitrogen is, however, of great importance as regards another set of chemical reactions taking place in the lower portions of the furnace.

It has long been known that when nascent potassium or sodium vapour finds itself simultaneously in contact with carbon and nitrogen, the three elements combine, forming a metallic cyanide; the following experiment illustrates this fact: a small charcoal furnace is fed with charcoal previously soaked in potassium carbonate solution and dried; a strong blast of air is then injected into the lower part of the furnace, all apertures being well closed up with clay: when the temperature attains a high enough degree cyanide of potassium is formed,* and escapes to some extent along with other potassium compounds in the form of white fumes carried up by the escaping gases: by diverting these gases through a lateral tube into a vertical tower filled with flints, the solid fume is to a great extent deposited on the surface of the flints; by pouring water down the tower the fume is dissolved and a solution of potassium cyanide (*inter alia*) trickles out at the base of the tower; on filtration and testing with ferrous and ferric salts and hydrochloric acid, this liquor gives an abundant Prussian-blue reaction, showing the presence of much potassium cyanide.

The cyanide thus formed acts on the last portions of unreduced oxide of iron, converting it into metal, and becoming itself changed to cyanate; at the high temperature of the furnace near the tuyeres this cyanate is probably decomposed with the formation of an alkaline carbonate, and the elimination of nitrogen. A portion of the alkaline carbonate is again converted into cyanide; the majority, however, escapes, and is carried upwards by the stream of gases, and condenses as a kind of sublimate on the surface of the materials in the upper part of the furnace: considerable quantities of cyanides are also carried up in this way. The alkaline salts thus condensed in the upper portions of the furnace are again brought down to the level of the tuyeres as the materials sink; hence each particle of alkali metal does duty over and over again, the alkalies introduced in small quantities in the fuel, etc., thus accumulating in the furnace to a very large extent. The enormous amounts of upwards of 4 cwt. of alkali metals and 2 cwt. of cyanogen per ton of iron made, have been repeatedly found in the gases near the level of the tuyeres. It appears very probable that the large excess of fuel required during the first few days of starting a new blast furnace is mainly due to the circumstance that cyanides have not formed to any great extent from the necessary want of this accumulation; after a very short time, however, considerable amounts of cyanides are found to be present in the gases.

These reactions afford an explanation of a circumstance which has for a long time been a difficulty in the minds of chemists who have studied the blast furnace. All observers agree that when the oxygen and carbon contained in the gases at various levels of the furnace are compared with the nitrogen, there is always more oxygen present than in ordinary air, and always more carbon than could be there were ordinary air burnt wholly to carbon oxide: thus the following Table illustrates the average composition by weight found by Bell in the case of an 80-foot furnace using calcinated limestone:—

Distance above Tuyere in feet.	0	6	12	25	37	50	60	76·5	Blast, if wholly burnt. To CO.	To. CO_2
Carbon dioxide	1·2	trace	0·8	1·2	1·6	1·2	3·5	7·9	—	29·2
Carbon oxide	37·6	37·1	35.9	34·9	34·8	34·8	33·2	33·0	34·4	—
Nitrogen	61·2	62·9	63·3	63·9	63·6	64·0	63·3	59·1	65·6	70·8
CARBON AND OXYGEN IN THE GASES AT DIFFERENT LEVELS, CALCULATED PER 100 OF NITROGEN.										
Carbon	26·8	25·2	24·6	23·9	24·1	23·8	24·0	27·5	22·5	11·3
Oxygen	36·5	33·7	33·3	32·6	33·1	32·4	33·9	41·6	30·0	30·0

The presence of this excess of oxygen is readily accounted for when it is remembered that even at the lowest portions of the furnace some oxygen is still left in

* The production of cyanide on the small scale in this way as a lecture illustration appears to be facilitated by the admixture of oxide of iron with the prepared charcoal, but is not always successful, the cause of failure being unknown.

the ore, which is eliminated only at that point, necessarily in association with carbon, and that at this level the nitrogen of the blast is partially removed in the formation of cyanides. The anomaly, however, presents itself that the amount of oxygen appears to *diminish* from the tuyeres to a point some 10-12 feet above them, whereas it might be expected to increase, since the reduction of iron oxide is going on in the interval between the tuyeres and this point; inasmuch, however, as nitrogen is probably eliminated from the cyanide by its reaction on the residual oxide of iron throughout the whole of this interval, it results that *the nitrogen increases relatively to the carbon and oxygen in the gases*; or, what is the same thing, these diminish in reference to the nitrogen.

We are now in a position to trace out the general chemical changes undergone by the oxide of iron in passing through the furnace; for this purpose we may divide the furnace into three regions: in the uppermost, tendencies [A] and [D] jointly are stronger than [B] and [C] jointly, and hence rapid reduction of ferric oxide takes place; in this region, too, tendency [C] is more powerful than [D] and [E] jointly, and hence carbon deposition takes place to a large extent. In this region, too, the limestone is for the most part calcined into quicklime, whilst if raw coal is the fuel employed, it is here coked: if carbonate of iron be used instead of oxide, it becomes converted into oxide in this region, the reducing and carbon-depositing reactions going on simultaneously with the formation of oxide.

In the middle region the iron-reducing tendencies are almost balanced by the iron-oxidizing ones, whilst the carbon-depositing tendencies are equalled and perhaps slightly excelled by the carbon-oxidizing tendencies; here reduction takes place, but only languidly, the chief effect produced in passing through this region being an increase of temperature.

In the lowest region, the reduction of the residual iron oxide is completed chiefly through the agency of the cyanides formed in the vicinity of the tuyere; the reduced iron melts, dissolving a certain amount of the finely-divided carbon in contact with it, together with small quantities of sulphur, silicon, and phosphorus reduced by subsidiary reactions. The earthy constituents of the ore and the lime of the limestone also fuse, forming "slag" as above described. In the act of cooling, this solution of amorphous carbon in molten pig iron undergoes a remarkable change, whereby the carbon is converted to a greater or less extent into the allotropic modification graphite, which is insoluble in molten iron, and so separates in crystals, thereby giving a crystalline structure to the pig, and forming "grey" iron of a quality varying with the nature of the foreign ingredients which retard the allotropic transformation: thus in white iron and in spiegel-eisen the transformation does not take place to any appreciable extent before solidification. This allotropic change is precisely similar to that undergone by a solution of yellow phosphorus in carbon disulphide by exposure to light; in each case the more stable allotrope formed (graphite and red phosphorus) possesses less "intrinsic chemical energy," *i.e.* gives out less heat on combustion, so that the allotropic change is attended with an evolution of heat.

This action of light on phosphorus is in several respects analogous to the changes produced in various attenuated vapours by passing a powerful beam of light through them, as ably described and illustrated in this room by your Professor of Physics on a former occasion.

Had time permitted, I should have wished to refer to the practical consequences of these researches of Mr. Bell. In order to effect the smelting of iron a certain definite amount of heat is required to perform the general work of the furnace; the various items in this amount are indicated by the following Table:—

Appropriation of Heat in an 80-foot Furnace, during the Production of 20 cwt. of Pig Iron from Cleveland Ore.

	Cwt. Heat-units.	
Constant requirements of furnace—		
Reduction of Fe from Fe_2O_3	33,108	
Impregnation with carbon	1,440	
Reduction of P, S, and Si	4,174	
Fusion of pig iron	6,600	
Radiation from walls of furnace	3,658	
Cooling tuyeres by water	1,818	
Conduction to earth, and other sources of loss not determined	3,202	
		54,000
Variable sources of loss of heat—		
Fusion of slag	16,720	
Expulsion of CO_2 from limestone	5,054	
Decomposition of ditto	5,248	
Decomposition of H_2O in blast	2,720	
Evaporation of H_2O in coke	313	
		30,055
Carried out by escaping gases		8,860
Total		92,915
Brought in by hot blast		11,919
Heat produced by combustion of coke		80,996

To produce this heat with a minimum expenditure of fuel, it is necessary that the whole of the carbon used as fuel should be oxidized in the furnace to carbon dioxide; the relative strength of the forces involved in the nine reactions above described are, however, such that it is not possible to convert more than about 35 or 40 per cent. of the carbon burnt into carbon dioxide, the rest necessarily escaping as carbon oxide. Hence much less heat is generated in the furnace than would be if the fuel could be wholly burnt to carbon dioxide; that is, more fuel must be used to do the work of the furnace. It hence results that if the exigencies of commerce or of nature should require that metallic iron should be obtained from its ores with the consumption of a materially less amount of fuel than is now necessary for the working of a blast furnace of the best description, some wholly dissimilar form of apparatus will be requisite for the purpose.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Adulteration of Food Act.

On Monday, July 13, Mr. R. Hill asked the President of the Local Government Board whether it was probable that he would be able to bring in a Bill during the present Session to give effect to the recommendations contained in the Report of the Committee on Adulteration of Food.

Mr. Sclater-Booth said when he moved in the early part of the Session for a Select Committee on the working of the Adulteration of Food Acts, he expressed an earnest hope that the Committee might be able so to restrict the number of witnesses to be examined, that it might be possible to legislate on the subject this year if legislation were found to be necessary. As the hon. gentleman was aware, that restriction was not found to be practicable, and the report of the Committee had only been in their hands within the last few days; it must be obvious, therefore, that it would be quite impossible for him to make any proposal on a matter of so much difficulty and interest in the limited time now available.

The Juries Bill.

On Tuesday, July 14, Mr. M. Lloyd asked the hon. member for Frome on what day he proposed to proceed with the Juries Bill, and whether he had any expectation that it would pass into law this Session.

Mr. Lopes said that, having regard to the late period of the Session and the amount of business which remained to be got through, he had no hope of passing the Bill this Session. He was sure, however, that, considering the principles of it had been sanctioned by the House, the public would not be satisfied until some such measure became law.

THE REPORT ON THE ADULTERATION ACT.—DEPUTATION TO THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.

A conference of the wholesale tea dealers of London was held on Monday afternoon at Messrs. Harrison and Crosfield's, Great Tower-street, "to consider the report of the Select Committee on the Adulteration of Food Act (1872), and to determine what steps shall be taken to urge the Government to suspend the operation of the Adulteration Act if it could not be amended this session." The chair was occupied by Mr. Smith Harrison. The Chairman briefly explained the object of the meeting, and said they had heard upon the very best authority that it was very unlikely that any amended legislation would be obtained this session. A very great portion of the trade thought it was their duty to at once go to the Government and ask for some relief for the retail dealers before an amended Act could come into operation. Prosecutions were still going on in various parts of the country, and the subject of those prosecutions had been exactly of the character for which the committee who recently sat upon the subject had recommended relief. What they wished the Government to do was, through the Local Government Board, to send out a circular to the various local sanitary authorities, informing them that until the Act has been amended all further prosecutions should cease.—Mr. Dummett (Messrs. Peek Bros.) then proposed the following resolution:—

"That this meeting desires to record its approval of the general tone and recommendations contained in the report of the parliamentary committee, and emphatically confirms the declaration of the committee that there is very little adulteration of tea in this country. It is believed it might safely have been said that there is no adulteration practised in this country."

Mr. Sanderson (Messrs. R. Davies and Co.) seconded the resolution, which was adopted unanimously.

Mr. Holborn then moved:—

"That this meeting resolves respectfully to recommend that in drawing the proposed amended Act, provision may be made to give substantial costs and damages to all defendants who prove themselves innocent of the charges brought against them. It is also strongly urged that an appeal be allowed to the analytical department at Somerset House before any local conviction be enforced."

Mr. Wilson seconded the motion, which was then put and adopted without opposition.

Mr. Samuel Edwards then proposed:—

"That this meeting also desires that the amended Act will definitely declare what per-centage of foreign matter shall be admitted for home consumption in those low-priced teas so largely consumed by the poor, which are not fraudulently adulterated by the Chinese grower, and are perfectly wholesome, though, from natural causes, they are not chemically pure. This meeting is of the judgment that 2½ per cent. would be amply sufficient to cover the facing of green tea, and that 5 per cent. is sufficient to allow for quartz and ferruginous sand in Canton-made scented teas."

Mr. Bransom seconded the motion. Messrs. Hilhouse, Steains, Bartlett, and others opposed the resolution, and upon being put to the meeting it was negatived.

It was then resolved that a deputation should be appointed to urge upon the Government the necessity of instructing the various local sanitary authorities who administer the Act to abstain from any further prosecutions until the Act has been amended in conformity with the recommendations of the parliamentary committee.

In compliance with the foregoing resolution a large and influential deputation waited upon the President of the Local Government Board, on Wednesday afternoon, to urge upon him the necessity for prohibiting any further prosecutions under the Adulteration Act until the Act is amended.

Mr. Alderman Cotton, in introducing the deputation, said the object of coming before him as the head of the Local Government Board was that when Mr. Crawford asked Mr. Gladstone to receive a deputation on the subject, Mr. Gladstone had said that there were no other means by which the object could be attained except through the Local Government Board, who had under their control all the appointments of analysts. Many persons had been convicted for selling adulterated tea, upon which the Customs had received 6*d.* per pound, and who were quite innocent of the act of adulteration.

Other gentlemen having spoken,

Mr. Sclater-Booth, in reply, said he must observe at once that the difficulty complained of was one which he was not then prepared to solve. It would be entirely out of his province to interfere with the decisions of the magisterial bench, which was more the duty of the Home Secretary, but he would consult with Mr. Cross and see what could be done in the matter, and whether he would be disposed to take any steps in the direction desired. With regard to the bodies who appointed analysts, it was quite out of the question to interfere with them. The statute law must be enforced, and there was no doubt in his mind but that the Acts had been of eminent value to the public generally, and if a few suffered it could not be helped. On the whole, he thoroughly believed with them that inconvenience and injury were done by indiscriminate prosecution, although he looked upon the passing of the Act as being productive of great benefit to the country at large. The deputation thanked the right hon. gentleman, and withdrew.

ALLEGED INFRINGEMENT OF A TRADE MARK.

At the Manchester County Petty Sessions, on Saturday, July 9th, before Sir John Iles Mantell and Mr. Peter Spence, A. Van Stan, cement maker, Bridport Street, Dorset Square, London, was summoned for infringing the trade-mark of Messrs. Samuel and Thomas Kay, chemists, Stockport. Mr. Cobbett was for the plaintiffs, and Mr. E. Atkinson for the defendant. It seems that in October, 1863, Mr. Samuel Kay invented a cement which he and his brother called "coaguline," and to give it notoriety registered a label with the word "coaguline" upon it. On the 25th May, Mr. Thomas Kay went to the Botanical Gardens, Old Trafford, where he saw the defendant selling cement in a tent, and in the tent, fixed in a conspicuous position, was a placard bearing the following words: "Coaguline Patent, for fixing flowers, mending relics and valuable china. Warranted to stand boiling water." Thomas Kay purchased a bottle, and then told defendant that he had better remove the card, but he refused, saying that he knew the law as well as the complainant. The summons was issued under the 25th and 26th Vict., cap. 88, section 7. Mr. Atkinson contended that the mere putting up of a placard in the tent bearing the word "coaguline" was not sufficient to amount to an offence under the section; the thing itself should be marked. Nor was there any intent to defraud shown. The defendant was fined £10, and 6d. for the bottle which he sold to the complainant.—*Manchester Evening Mail.*

PROSECUTIONS UNDER THE ADULTERATION ACT.

At the Westminster police court, Mr. Alfred Harvey, of 105, Buckingham Palace Road; Mr. Henry Hankin, of Lupus Street; and seven other persons, were summoned by Mr. Dixon, one of the sanitary inspectors for the vestry of St. George's, Hanover Square, for selling, as pure, coffee adulterated with chicory. Mr. Hitchen, solicitor to the vestry, prosecuted, and called William Banks, a messenger, who said that on the 18th of June he went to Mr. Hankin's shop and purchased a quarter of a pound of 16d. coffee, which was duly sent to the analyst. Mr. Smyth, who appeared for the defence, asked the witness what was said by the defendant's man at the time. Witness answered, he said, "You won't get coffee for 1s. 4d.; you will get a mixture of chicory and coffee." Mr. Bridge asked Mr. Hitchen if he would go on any further after that answer? Mr. Hitchen was afraid he could not. Mr. Smyth said not only was the witness told that it was a mixture, but the paper was labelled "chicory and coffee," and a written notice was served on the purchaser at the time that it was chicory and coffee. He therefore asked that the summons be dismissed with costs. Mr. Bridge said that he should give the defendant a guinea costs; when tradesmen were brought to the court on a flimsy pretext he should mark his sense of the matter by inflicting costs. Mr. Hitchen hoped that course would not be adopted, as the officer was only performing a public duty. Mr. Bridge said tradesmen were not to be harassed like this; the greatest possible carelessness had been exhibited. Mr. Hitchen said the costs would fall not on the inspector but the ratepayers. Mr. Bridge said the officer who took out these summonses was guilty of the greatest possible negligence, and the ratepayers or parish should make him pay the costs.

At Clerkenwell, William Odell, chandler, of 13, Great Warner Street, Clerkenwell, was summoned by Mr. William Thorn, sanitary inspector of Clerkenwell, for having sold vinegar which was adulterated with sulphuric acid. The defendant said he sold it as he received it. He was not aware that it was adulterated, for he bought it as pure and sold it as such. Dr. Redwood, professor of chemistry to the Pharmaceutical Society, said he had analysed the vinegar purchased at the defendant's shop, and he was of opinion that it had been adulterated by the addition of sulphuric acid. He was further of opinion that the adulteration was not necessarily injurious to health. Mr. Barker said he was quite willing to believe the defence set up, but still the defendant was liable. He then ordered the defendant to pay a fine of 20*s*. and 2*s*. costs.

James Corder, chandler, of 31, Cold Bath Square, Clerkenwell, was likewise summoned for selling vinegar that had been adulterated with sulphuric acid. The defendant said he sold the vinegar as he purchased it. He thought it was a great hardship that the retail dealer should be summoned and the wholesale dealer should escape with impunity. Mr. Barker fined the defendant 20*s*. and costs.

Obituary.

Notice has been received of the death of the following:—

On the 2nd June, 1874, Mr. William Short, Chemist and Druggist, of Tattershall. Mr. Short had been an Associate of the Society since 1868.

On the 2nd May, 1874, Mr. Thomas Fisher, Chemist and Druggist, of Horwich, near Bolton.

On the 10th May, 1874, Mr. Robert Atkinson Ryott, Chemist and Druggist, of Newbury.

On the 21st June, 1874, Mr. William Bicknell, Chemist and Druggist, of Ebury Street, London.

On the 27th June, 1874, Mr. William Balgaley Fletcher, Chemist and Druggist, of Rainford.

On the 1st July, 1874, Mr. William Benjamin Ward, Chemist and Druggist, of Little Lever, near Bolton-le-Moors.

Notes and Queries.

[403.] BLEACHING OF CORAL.—Wash thoroughly from all impurities, and then expose in the sun till perfectly bleached.—H. C. Baildon.

[403.] BLEACHING OF CORAL.—In answer to "*Incognitus*," I beg to state that coral may be rendered quite white by immersing it in a solution of hydrochloric acid, one part of B. P. acid to 30 parts of water, and keeping the coral in until it appears to be pure white; it should then be taken out, and well washed in cold water, and allowed to dry.—John C. Hunter.

[.] RESTORATION OF THE COLOUR OF FERNS.—A correspondent writes, that having been asked the best way to restore somewhat the colour of fern leaves which have become brown, he would be obliged to any person who could suggest any method of rendering them more sightly. They are a valuable collection of Indian ferns, the lady who has collected them having just brought them to England, and is rather disappointed at the appearance they present.

[.] CHARCOAL FOR FILTERING PURPOSES.—*W. Creig* asks for information respecting the best method of cementing granulated charcoal for filtering purposes.

Correspondence.

Fluid Meat.

Sir,—In your review of Dr. Pavy's recent 'Treatise on Food, etc.,' having mentioned in terms of commendation my preparation called "Fluid Meat" (the suggestion to prepare which was first made to me by Dr. Pavy), you go on to state that "a similar preparation, though made by a different process, is now being employed in Germany."

Inferring the preparation thus referred to to be that of Dr. Leube, of Jena, and mentioned in 'Volkmann's Sammlung-klinischer Vorträge,' I would beg your permission to point out that *the two preparations are quite dissimilar*, and Dr. Leube's does not claim to possess the peculiar advantages of "Fluid Meat."

In "Fluid Meat" the albumen and *fibrin* are by the action of pepsin, in an acid solution and at a suitable temperature, rendered perfectly and permanently soluble in water, changed in fact to the condition known as peptone.

Dr. Leube's preparation I have not yet had an opportunity of examining, but it is described as a fine emulsion having a slimy consistence;—evidently meat in a finely divided state, but the fibrin of which will, I would submit, be mostly insoluble, and from the treatment it has undergone, in a condition most difficult for conversion by the digestive functions. It is obtained by the action of acid on meat at a high temperature. This treatment of meat is one with which I formerly gained some acquaintance when endeavouring to avoid the intensely bitter flavour *always* evolved when meat is *digested*, and which is removed only by the action of the pancreatic fluid. That portion of the fibrin of meat which by treatment with acid is gelatinized becomes, on removing the acid, again insoluble, unless the process has been carried so far as to effect its conversion into other compounds, the properties of which as nutritive agents would yet require confirmation.

The action which, severally or collectively, the various agents, coming in the digestive process, exert on the fibrine and albumen of flesh is of much interest chemically, to say nothing of the importance of this knowledge to the physiologist and physician.

The great power which "Fluid Meat" possesses as an article of nutrition, and for which it is highly valued by many medical men, some of them amongst the most eminent, is, I think, yet scarcely appreciated by a large majority of that profession to whom we look for alleviation and prevention of disease.

Trusting that the desirability of avoiding any misconception on a subject so important as dietetics will be sufficient apology for my requesting an insertion of the foregoing in your journal.

STEPHEN DARBY.

Leadenhall Street, July 6th, 1874.

[*₊* We have communicated with the reviewer of Dr. Pavy's work on the subject of Mr. Darby's letter, and learn that he is of opinion that the German preparation referred to does possess the same properties as the "fluid meat;" that is to say, they both consist of peplones. In regard to Mr. Darby's assumption that the fibrin in the German preparation is insoluble, he refers to the proof given by Von Wittich that fibrin is converted into true peplone by acid and heat, just as by acid and ferment. At the same time, he considers that "fluid meat" is a most valuable preparation, and that Mr. Darby is quite right in saying it is not sufficiently appreciated. We hope that Mr. Darby will shortly make known the results of his experiments with this preparation.—ED. PHARM. JOURN.]

SCAMMONY.

Sir,—It is not my intention to reply to Professor Attfield's taunts, for if I desired to repay him, I would do so in sterling currency, and not in tattered figments of worn-out coin.

My letter was addressed to you honestly, and I did not screen myself behind any anonymous cognomen. For Professor Attfield I entertain the respect which is due to a chemist of his standing; but I deny that I am obliged to accept the words of his mouth as infallible proof in regard to the genuineness of any article which he has examined. I mean no offence thereby. I have not failed to catch the true tenor of the trial; but I do not see through the tinted glasses of a paid witness.

I still maintain Professor Attfield failed to give the correct data. He was bound to give 90 per cent. as well as 80; but I suppose it would not have suited. I beg to remind Professor Attfield I quoted authorities, as will be seen on referring to my letter. I am inclined to think it would have been rather unpleasant information had the maximum percentage been given.

In this country we have nothing to do with the standards of the United States or French Pharmacopœia. In English law courts those books are no better than waste paper, so long as we have a national guide. Professor Attfield seems offended because I suggest the magistrates should be chary in receiving evidence from experts. I am sorry I cannot alter my views, and I hope the day is not far distant when magistrates will see the necessity of calling an accomplished chemist to consult with, and that independently of the evidence of public or paid analysts.

What a perfect farce it is to see medical men and chemists and analysts pitted against each other in our law courts. What a sorry figure is too often portrayed!

One swears one thing, and the next witness flatly contradicts his predecessor in the box.

And, behold! we are to expect justice and fair measuring out of equity from the commingling and jumbling caused by experts.

The system, as at present carried out, is the best possible one to frustrate the ends of justice, and it very seldom fails to do so.

As soon as a prosecution is contemplated, a war-cry is raised, and the question is, "Will the trade suffer?" not "Will justice be measured out?" I hope, Sir, your correspondent, Professor Attfield, will pardon my plainness of speech; and let me say there is no use indulging his proclivity for personalities any longer. We have seen what he can do, and the sight is not edifying.

HENRY BROWN, L.R.C.P., L.R.C.S.

Northallerton, 11th July, 1874.

EXCESSIVE LABOUR IN PHARMACY.

Sir,—The letter of "A Country Major Associate" is one which, I think, will be noticed by many who are similarly situated to himself; and I consider the term pharmaceutical slave is a most fitting one for a large per-centage of those engaged in pharmacy. If there is not a change for the better, both in hours of labour and remuneration, I would rather have a son of mine as a mechanic than a pharmaceutical chemist; as, in the former, he would not only be better paid but have greater scope for advancement, and not be compelled to keep up appearances under false pretences. Why should we work so long? Why, indeed? I firmly believe there is no necessity for it, and if a certain time for closing were adopted by all the chemists in a town, the public would learn to procure what they required. Medical men, also, would pay their visits earlier and give their directions; and there would be few cases of such urgency as to require attention, except in case of sudden illness in the night time, and then we are all liable to be called up. If chemists would be united, and do away with petty jealousies, of which, I fear, there is a large amount existing in most country towns; if they did not hold aloof from each other as they unfortunately do, but would meet, as members of other professions are in the habit of doing, and discuss matters of interest and mutual advantage, not only might the hours of labour be curtailed, but unremunerative prices and underselling might be stopped. The remedy is in our own hands, and if principals will not help themselves, the assistants and outsiders must be the ones to effect a reformation; and I would strongly urge all assistants in the country not to take a situation where the hours are longer than from eight a.m. to seven p.m.; and to parents I would say, Do not article your son to a chemist where longer hours are kept, but have the above time specified in the indenture. I do not agree with your correspondent's suggestion of one half-holiday in the week. This has been tried in many towns, and, as a rule, I believe has worked badly in all cases that I know of, and has been a source of annoyance to many. I hope to see more correspondence on the subject, and trust our efforts to do away with an abuse will not end in verbiage.

SEVEN O'CLOCK.

Lancaster, June 27th, 1874.

HUNTER *v.* FREELAND.

Sir,—The following subscriptions, in addition to those announced on p. 1052 of the last volume, have been received on behalf of the fund raised to re-imburse Mr. Freeland, Bathgate, for the heavy expenses—amounting to £267—incurred in defending himself in the case of "Hunter *v.* Freeland:"—

	£	*s.*	*d.*		£	*s.*	*d.*

G. Watt.—The specimen belongs to a species of cypress, but in the absence of fruit we are enable to say which.

J.—(1) *Torilis Anthriscus.* (2) *Chærophyllum temulum.* (3) *Ægopodium Podagraria.* Leaves and fruit of Umbelliferæ should always be sent.

G. C. Druce.—The specimen appears to be a variety of *C. divulsa.*

R. S.—Mr. Squire, in his 'Companion,' recommends a syrup containing 4½ grains of bromide of iron to the drachm.

J. J. Macaulay.—Yes.

A. Thomas, 11, *Union Street, Carmarthen.*—We are unable to comply with your request that we should return your 4½*d.* as it has been forwarded in the usual course to the publisher, to whom we refer you generally in regard to the subject mentioned in your post-card.

We take this opportunity of referring you to the publisher's announcements of the mode in which this journal may be obtained, tariff for advertisements, etc., which appear every week, in the earlier pages of the journal, and we are disposed to believe that a perusal of those announcements will enable you to perceive something more fitly calculated to merit your disgust than the way business is transacted at our office.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Bale, Conundrum, Inquirer, G. C. L., A. P. S.

THE OILS OF CHINESE PHARMACY AND COMMERCE.

BY DR. F. PORTER SMITH,

Honorary Member of the Pharmaceutical Society of Great Britain.

The word for oil in Chinese is written as a compound of the characters for liquidity and let. Oil thus means with them the "letting liquid," that which removes the hindrance of friction. The enormous demand for oil as an article of daily diet to counteract the binding qualities of rice and other cereal foods, and in pastry-making, and the extensive use of varnishes, putties, paints, and pigments in China, lead to the manufacture of oil from all sorts of sources. Oil is exclusively used for lighting purposes in all stationary situations. It also enters into the composition of quack and orthodox plasters, a very favourite application in Chinese medicine and surgery. By the use of night-soil, on an extensive scale, in the form of irrigation, the rapid growth of enormous breadths of Cruciferous plants (a populous order in China) enables the Chinese to obtain large quantities of oil from this source. These colza-oils are miscalled olive-oil in some European manuals on China. The olive-tree is not known in China. Certain extracts are sometimes called oils in Chinese nomenclature. Soy is called an oil.

OIL OF ALMONDS (SWEET).—A bland oil is said by Sir J. Davis to be obtained from the (mixed ?) kernels of the apricot or almond-trees in North China, but I have never met with it

OIL OF (STAR) ANISE.—This oil is said by Dr. S. Wells Williams to be prepared from the fruits in small retorts, a hundredweight yielding about seven pounds of the oil. It is pale, warm, and sweetish, and becomes solid at about 50°. It is used as a condiment and cordial in South China, and is exported thence to Europe and the United States. The common anise-oil has not been met with by me in China.

OIL OF APRICOT SEEDS.—See Oil of Almonds.

OIL OF BEANS.—This oil is expressed in large quantities in North China, and at Newchwang, from the Dolichos Soja bean, by both natives and foreigners. The oil is often miscalled pea-oil, is dark, not very palatable, and has some tendency to cause sickness. It is used in cooking very largely, and is very cheap.

OIL OF BENZOIN.—A fragrant, oily preparation is sold under this name, but it is not liquid benzoin. Dr. Williams says it comes from India. It is used in making ointments and plasters. It is probably liquid storax, or the rose-maloes of commerce.

OIL OF CABBAGE.—This oil, a kind of colza-oil, is expressed from the seeds of *Brassica Sinensis*, in increasing quantities, all through the valleys of the Yang-tsze and Han rivers. Very primitive machinery is used for this purpose. The seeds are crushed, steamed, and put into wooden cylinders, usually made by hollowing out the trunks of trees. The oil is squeezed out of the mass placed in coarse bags, by means of wedges driven down by mallets, or by an arrangement similar to that by means of which piles are generally driven into the earth in this country. In the last case water-power is sometimes employed. The proportional yield is very considerable. The oil is of a dark yellow colour, thick, and has a pleasant odour. It is used for lamps, in cooking, and as a hair-oil. It is laxative, or even purgative to some extent, and applied to swellings, sores, and ulcers.

OIL OF CAMELLIA.—This oil is prepared from the seeds of the capsular fruit of the *Camellia oleifera*, or mountain tea-tree, as the Chinese call this shrub, which grows in the same situation and soil as the tea-shrub proper, known by the same generic name, *Ch'a* or *Ts'a*. This tea-oil, as it is miscalled by foreigners in China, is thinnish, yellow, and less fragrant than cabbage-oil. Large quantities of this oil come from the hilly districts of Kiang-si and Hunan provinces, where the shrub grows in profusion.

OIL OF CAMPHOR.—Oily or uncrystallizable camphor is obtained in the island of Formosa, in the form of a yellow, strong-smelling liquid, which exudes from the crude native camphor, stored in tubs or vats, to the extent of some 3 or 4 per cent. It is scarcely saleable, and is altogether inferior to the oil obtained from the *Dryobalanops camphora*, on the west coast of Sumatra, where the oil dripping from the split timber of the tree, felled to procure the Borneo or Baros camphor, is sold at the price of a Dutch guilder for a large quart bottleful. It would be worth importing to England for use as a cheap substitute for the Lin. Camphoræ. It answers capitally as an embrocation in rheumatism and sprains.

OIL OF CHAULMUGRA. This oil is made from the seeds of the *Gynocardia odorata*, or lucrubau fruits. The oil is both cold-drawn and made by superheating the crushed seeds. It is used in leprosy as an outward application, with doubtfnl ben fit, and is *useful* in the treatment of pediculi and itch.

OIL OF CINNAMON OR CASSIA.—This volatile oil, obtained from the leaves and twigs of the cassia-tree by distillation, is made in Canton, and regularly exported. It is the *Oleum Malabathri* of commerce. This oil is nearly as good as the Ceylon oil.

OIL OF CLOVES.—A well-made, heavy, acrid oil, of a pale, reddish-brown colour, becoming very dark by age and exposure to light. None of these essential oils were known to the old medical writers in China, and are, therefore, not met with, as a rule, in their Pharmacopœia or Herbal. They are nearly all made at Canton, and are obvious imitations of European articles of commerce.

OIL OF COTTON SEEDS.—The oil expressed from the seeds of *Gossypium herbaceum*, and *G. religiosum*, is commonly used for purposes of illumination in Chinese country villages, where all wants are met on the spot in the most primitive fashion. It is also used in cooking, but the taste is unpleasant. It is prescribed as a demulcent remedy, and is applied to leprous, scabious, and other forms of skin disease, so fearfully prevalent in China.

OIL OF FISH.—The Chinese do not, as far as I can learn, extract oil from the liver of any fish, but there is an oil called *Yu-san*, prepared from the entrails, etc., of a fish. The cod has not been met with in Chinese waters. Large quantities of a fish resembling the cod are caught off the coast of the Chehkiang (or Ningpo) province, in the sixth or seventh (Chinese) months. The oil obtained from the porpoise (or "river-pig," as they call it), which frequents the Yang-tsze-Kiang river as far up as Hankow, is used to make putty for caulking vessels, and to burn in ship lamps. A yellow oil obtained from a fish, called *Hwang-ku-yu*, has a strong fishy smell, and is used to destroy lice. It is much used in veterinary medical practice, a department of the Chinese medical art which has been practised from an early period, and has an ancient and respectable literature of its own.

Oil of Ground Nuts.—This pale yellow oil, having an agreeable flavour, is expressed in large quantities from the seeds of the *Arachis hypogœa*, or underground nut. Hunan province supplies a good deal. It is very cheap, and makes a fair substitute for olive oil. The Chinese samples are much darker than the Indian, which are said by Dr. Waring to have a specific gravity of ·916.

Oil of Hemp Seeds.—Several hemp oils, derived from the seeds of a variety of the *Cannabis sativa*, are to be met with in Chinese commerce. Specimens examined were evidently oils obtained from sesamum seeds, or those of the flax plant, both of which are confounded with the hemp plant proper.

Oil of Lilies.—This is cabbage oil, in which the axillary buds of the lily plant have been digested. The oil is recommended to be applied to vesicular eruptions. This very same, or a similar, preparation was once in great repute in Europe. In fact, to read the Chinese Pharmacopœia of to-day is like reading the old dispensatories of the 17th and 18th centuries.

Oil of Linseed.—The oil of the seeds of a linum is used as a lenitive, pectoral, anthelmintic, and alexipharmic remedy, and as an application to scabbed heads. This oil is not easily procurable.

Oil of Myrrh.—A reddish oil, having the smell of myrrh, is said by Loureiro to be used in Cochin China to dress ulcers. The Chinese are fond of making empyreumatic oils of various substances.

Oil of Pine.—A sort of empyreumatic oil, or coarse turpentine, procured by heating the wood or knots of several species of *Pinus*.

Oil of Peppermint.—A very good essential oil is distilled at Canton from the leaves of *Mentha piperita*, *M. crispa*, *M. hirsuta*, and *M. Canadensis*. It is put up in small bottles holding about a drachm. It sells at about 30*s.* a pound. The Chinese bottles are very poor, and stand a good deal in the way of elegant pharmacy. There are several glass manufactories in the (north-eastern) province of Shantung and at Canton. The bottles are very small and brittle. The Chinese pharmacists decorate their shops with ginger-jars and small blue-ware bottles. An oil is prepared at Canton from the pennyroyal plant. Mint is largely used as a remedy in belly-ache, but the dried leaves are generally used as an infusion.

Oil of Persimmons.—A glutinous oily extract is prepared from the fruit of the persimmon, a large, soft, orange-yellow fruit, very sweet, and often somewhat acrid. The fruit chosen for making this oil is that of the *Diospyros Embryopteris* or *Embryopteris glutinifera*, which grows plentifully in Hupeh province. The fruits are crushed to obtain the dark, resinous, thick juice, which makes a very capital varnish for the paper kittysols, or umbrellas of China. It is very cheap. An extract might be prepared from the fruit, as directed in the Indian Pharmacopœia, where it is prescribed as an astringent.

Oil of Poppy Seeds.—The opium poppy is largely grown in Sechuen, Yunnan and every province of China. It was introduced from Persia, a great source of drugs sent as tribute to China. Several splendid varieties of the flower are given in old lists of plants. Oil is obtained from the seeds, but I have never inspected a sample.

Oil of Ricinus Communis.—The castor oil plant grows to the height of more than ten feet, and forms a woody stem in Hupeh, but never survives the winter there. There is a red-stemmed variety and a white-stemmed plant, both of which are used to make the oil, which is used in cooking, and is sold for use as a lubricant on board foreign steamers. It is used medicinally, but not very frequently, as it does not purge Chinamen much, if at all. Croton oil is used by Chinese physicians in apoplexy, a common disease in China.

Oil of Roses.—This essential oil is used mainly as a scent for hair oil, so plentifully used by all Chinese women.

Oil of Sandal Wood.—The Chinese employ this thick, yellow, fragrant oil to daub over common fans, which are then sold as genuine sandal-wood fans.

Oil of Sesamum.—The black and white sesamum seeds are used to make an agreeable oil, much used by the higher classes in cooking food and making pastry. It is credited in the Chinese Pharmacopœia with ecbolic, emmenagogue, and anthelmintic properties. It answers all the purposes of olive oil in the dispensary. It is the Til or Jinjili oil of India.

Oil of Sunflower.—This oil is known to the Chinese, but is not extensively used or known to be employed in pharmacy.

Oil of Spike.—A fine drying oil, is used in painting on porcelain and for varnishing. It is obtained from the Lavandula or an Ocymum. The Labiates do not abound in China, but they are held in great repute medicinally.

Oil of Tallow Seeds.—This oil, made from the albumen of the seeds of the tallow tree or *Excœcaria sebifera*, is clear but of a dark colour. It is obtained, in the proportion of from 15 to 16 lbs. from one hundredweight of the berries, by grinding, steaming, and pressing the refuse which results from the preparation of the vegetable tallow. The oil is used to varnish umbrellas, to dress the hair, and to mix with the tallow to make the candles which form so effective a part of the religious ceremonies of Buddhism, the Ritualism of China. It has emetic and purgative properties. It is one of the few remedies given by the Chinese in cases of poisoning. Efforts are seldom made to rescue those suffering from opium-poisoning, a common mode of suicide in China.

It will be observed that the oils of Chinese commerce are almost exclusively taken from vegetable sources. This is one of the effects of Buddhism on their national life and economy. As Buddhism teaches that mercy and pity are noble sentiments, it forbids the destruction of animal life. The flesh of the cow and the sheep is never eaten by orthodox Chinese members of the Buddhist Church. Their wax is, therefore, vegetable, their tallow is vegetable, and their oils are vegetable. Their gelatines are made from sea-weed. Their daily diet is fish, oil, and rice, with an occasional treat of pork.

There are many other vegetable substances, such as gourd seeds, the fruit of the *Aleurites triloba*, etc., from which the Chinese might prepare, or formerly have prepared, vegetable fats, in obedience to their strong religious teachings and highly economic tendencies. Mineral or rock oils are met with in Shansi, Sechuen, and Formosa, and in Corea. They are not used for illuminating purposes, as they are very inflammable, and are said to have been employed in warfare in the composition of a sort of Greek fire.

TARTAR EMETIC AND OTHER ANTIMONIAL PREPARATIONS.*

BY THOMAS WILLIAMS, F.C.S.

My object in taking up the investigation of antimonial preparations has been to ascertain the purity of trade specimens, especially as to the presence of arsenic. The great importance attached to their being free of this element is admitted on all sides. And yet when we look through the ordinary processes by which antimonial remedies are obtained, and to the one source they are drawn from, the probability of arsenic being present in all the resulting products strongly suggests itself to us. This view has moreover been confirmed by the researches of several authors, who state that they have frequently found arsenic in antimonial products; and from this circumstance they have devised special and reliable methods for its detection. The results I now bring forward do not, however, indicate the present produce to be of so unsatisfactory a quality. The questions here arise—how then has such a degree of freedom from arsenic been attained? and how is it that the antimony, in the tartar emetic especially, stands out so high? These are points that I am as yet unable to explain, but I have arranged to continue a further investigation into the matter.

Antimony occurs in nature in a variety of combinations; occasionally it is found native, also alloyed with the metals nickel, silver, arsenic, etc. Some natural oxides and oxysulphide, or Kermes mineral, are also obtained. Its sulphide occurs abundantly, associated with sulphides of lead, silver, iron, etc. Our commercial supply, however, consists exclusively of the natural sulphide known as antimonite, stibnite, black antimony, etc. This exists at various places in the United Kingdom and foreign countries. The earthy matter, or gangue, that accompanies it into the manufactory is chiefly quartz, lime, and alumina. From these it is freed by charging a crucible, through the bottom of which a hole has been pierced, and placing it in a furnace. A moderate degree of heat liquefies the sulphide, and it runs into a receiver below, leaving the earthy impurities as a solid refuse or slag in the crucible. Thus we obtain, out of the rough ore, the B. P. antim. nigrum, or the commercial crude antimony. This substance, when ground and mixed with a definite amount of iron, yields by fusion the metal antimony or the crude regulus of commerce.

Some of the antimonial compounds were known and utilized in the earliest times. The regulus, or the metal, however, was not known until towards the end of the 15th century, when a method of preparing it was discovered by Basil Valentine. The sulphide, from the most remote antiquity down to the present time, has been used as a pigment for staining the eye-lids, making the eyes appear large, a feature, considered by those who practised it, of great splendour. Basil Valentine has the credit also of being the first to apply antimonial and other metallic remedies for internal administration; though tradition tells us that unlucky results happened from his first experiments upon his brother monks. The reputation of antimonial preparations stands, however, foremost to this day, as affording the most valuable and active metallic medicines in practice. We turn our attention now, then, to the one source they are derived from—the antimonite. The evil complained of in the sulphide, usually, is arsenic in particular; and we read besides that specimens have been found adulterated with smithy scales, and in other instances with galena or lead sulphide. My own analysis of sample No. 1 antimonite shows a minimum of silica and iron. A close examination qualitatively upon sample No. 2 enabled me to consider it equally good: from lead and arsenic they might, practically, be pronounced free. Whence these came from originally I cannot tell, but it is generally believed that we are supplied from abroad. Ure's Dictionary of Arts, Mines, etc., gives the quantity imported into this country during 1856, as follows, Ore 1750 *tons*, Crude 3121 *cwt.*, Regulus 1004 *cwt.* The annual mineral statistics of the United Kingdom, though they include our home produce of arsenic, bismuth, tungsten, cobalt, etc., do not mention antimony in any form. On the other hand, we read that the principal sources abroad are in France and Germany, with the statement that most if not all the sulphide raised at those places contains from $\frac{1}{60}$ to $\frac{1}{20}$ its weight of arsenic—that the regulus obtained from it holds $\frac{1}{200}$ to $\frac{1}{35}$ its weight of arsenic, and the Kermes $\frac{1}{100}$ to $\frac{1}{300}$. There are practicable methods for the purification of the sulphide from the metallic matters it contains; but I am not aware that this is done, except when the object is to obtain pure antimony metal. The prepared sulphide (antimonium nigrum), by fusion, is used by pharmaceutists to make the oxysulphide (antimonium sulphuratum). The B. P. process takes 10 oz. of the sulphide; this is boiled with 4½ pints soda solution over two hours, the volume of liquid being maintained constantly by the addition of distilled water from time to time. It is then strained through calico, and to the liquid, before it cools, dilute sulphuric acid is added in slight excess. A precipitate is thus formed; it is collected upon a filter, washed with distilled water, until the washings no longer precipitate barium chloride solution, dried at 212° F., and this is the orange-red powder sold. The other pharmaceutical preparation obtained direct from the sulphide is the liquor antimonii; chloridi. The B P. process takes of the sulphide one pound; this is placed in a porcelain dish, along with 4 pints hydrochloric acid, and heated gently, with constant stirring, beneath a chimney, until the liquid boils and all the sulphuretted hydrogen is driven off. It is then filtered through calico, the filtrate boiled down to the bulk of two pints, and the result is a liquid of 1·47 s.p.g., coloured more or less according to the amount of iron contained in the sulphide.

Reaction :—$Sb_2S_3 + 6\ HCl = 2\ SbCl_3 + 3H_2S$.

This solution is used for obtaining antimonii oxidum, B. P. We take 16 fluid ounces of it, and pour into 2 gallons of water, shaking them well together; a precipitate of antimony oxychloride subsides. The supernatant acid liquid is syphoned off, then it is well stirred up with distilled water, repeating this and the syphoning of the wash-water away. Next a solution of 6 ounces sodium carbonate in 2 pints of distilled water is added to the precipitate, and left together half an hour, with frequent stirring; the deposit is then collected upon a calico filter, washed with boiling distilled water, until the washings cease to give a precipitate with silver nitrate solution acidified with nitric acid. Lastly it is dried at 212°.

The reactions are :—

$$12SbCl_3 + 15H_2O = 2SbCl_3,\ 5Sb_2O_3 + 30HCl$$
$$2SbCl_3,\ 5Sb_2O_3 + 3Na_2CO_3 = 6Sb_2O_3 + 6NaCl + 3CO_2.$$

---

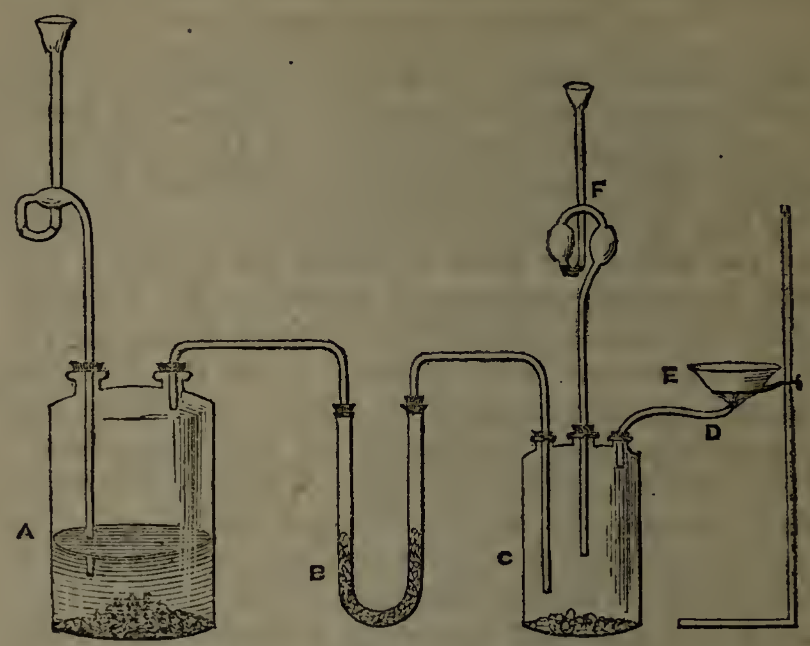
* Paper read at a meeting of the Liverpool Chemists' Association, May 17th, 1874.

With this oxide, tartar emetic is made. The official method takes five ounces of it and six ounces of acid tartrate of potash in fine powder; to these distilled water is added to form a paste, which is set aside for 24 hours. It is then made with distilled water to the bulk of two pints, boiled for 15 minutes, with constant stirring, filtered, and set aside to crystallize. Tartar emetic crystals lose, upon exposure to air, a portion of their water of crystallization, and become opaque. At 212°, the whole is driven off; and upon being heated still higher, the elements of water unite, incurring a further loss, varying according to time and temperature.

This salt is generally stated to have been discovered about the year 1631 by Mynsicht, but it was previously mentioned by Basil Valentine towards the end of the 15th century. Tartar emetic dissolves in 15 parts of water at 60°, and in about two parts at 212°. The B.P. test allows 21·8 parts of water at 60° for its solution. Even that quantity affords abundant facility to detect a somewhat large excess of, or adulteration by, cream of tartar, for this latter takes above 200 parts of water at 60° for its solution.*

Metallic antimony combines very energetically with most of the non-metals, thus if it is in the state of powder introduced into chlorine it burns instantly and produces chloride. It also readily alloys with most of the metals; arsenic behaves similarly, producing alloys. Thus antimony or arsenic may be alloyed with metallic potassium direct; or we may submit to a high temperature, in a covered crucible, any arsenical or antimonial compound in admixture with an organic potassium salt, and we obtain in the case of antimony an alloy containing about 12 per cent. of potassium. If this alloy is placed in water, the potassium leaves the antimony, and, acting upon the water, it liberates hydrogen gas only; when, however, arsenic is either alloyed alone with potassium, or conjointly with antimony, we have arseniuretted hydrogen gas evolved upon contact with water. From this fact, one standard author, at least, recommends this as "one of the best methods of detecting the presence of the least trace of arsenic in antimonial substances," giving a diagram of an ordinary capacious hydrogen bottle, for the guidance of his readers. I would mention, however, that the first trial I had of this method proved a failure. I made an alloy from two ounces of tartar emetic (with this substance it is not necessary, of course, to add any separate organic potassium salt), and placed it aside in a tightly corked bottle, until I had an opportunity to proceed further. After three days I pounded it and placed it in the hydrogen bottle with some water, and there was only the minutest quantity of gas produced. I repeated the test with another two ounces of tartar emetic, placing the alloy, immediately the crucible was cooled sufficiently to be broken, in the hydrogen generator, with very little water; the action in this instance was evidently more lively, but the amount of hydrogen evolved was so small that there was no hope of anything but an explosion occurring if a light were applied to the jet. After repeated experiments I have devised the following apparatus, a diagram of which, with the *modus operandi*, is given below. I may state that this method, with due precautions, will indicate the presence of the minutest trace of arsenic.

* Mr. Hennell states—*vide* 'Philips's Pharmacopœia Londinensis,' 5th edition—that tartar emetic may contain even 10 per cent. of cream of tartar, and still be dissolved in the prescribed quantity of water.



METHOD A FOR ARSENIC.

In the above diagram, A represents the hydrogen generator; B a U-tube, containing fragments of pumice stone, moistened with strong sulphuric acid; C the bottle which contains the alloy; D the jet tube; E glazed porcelain dish, against which the flame is depressed; and it should contain cold water, so that the arsenical mirror once deposited may not volatilize away by a prolonged contact of the flame and overheating of the dish. *Modus operandi*—an ounce of tartar emetic, or about half-ounce of other preparations of antimony, mixed with equal weight or rather more of cream of tartar, is introduced into a clay crucible, covered and subjected to a bright red heat for forty minutes. As soon as the crucible is cold it is carefully broken, and the alloy button, cleaned of its slag, is pounded and placed in bottle C. Hydrogen is now generated in bottle A, by zinc and dilute sulphuric acid; the gas is dried by passing through the tube B, and is allowed to go on until all the air is displaced from the apparatus. A light is at this stage applied to the jet tube D, to establish the purity of the hydrogen; and then some half-an-ounce of water is introduced down the double-bulbed funnel-tube F to the alloy, when an arsenical mirror will be produced, if arsenic is present in the original sample. For the success of the experiment, it is necessary that the bottle C is of the smallest possible capacity, and, with its funnel, absolutely dry when the alloy is placed in it. To prevent the escape of gas through the funnel-tube, as little mercury as will plug the bend is poured down the funnel.

Method B is founded on the fact, that recently precipitated arsenious sulphide is soluble in potassium bisulphite, while antimony sulphide is insoluble. A gramme of the substance, mixed with half its weight of sulphur, is digested in a tolerably strong solution of potassium protosulphide, filtered, the filtrate diluted, and a strong solution of sulphurous acid added, in excess, and boiled for a length of time. The antimony sulphide is then filtered off; and sulphuretted hydrogen, passed through the filtrate, will produce a yellow precipitate of arsenious sulphide, if present in the substance.

Method C.—Two grammes of tartar emetic is dissolved in four grammes of chemically pure hydrochloric acid, sp gr. 1·124, in a test tube; 30 grammes of hydrochloric acid, saturated with sulphuretted hydrogen, is then added; the solution, after standing some time, will yield a yellow precipitate of arsenic sulphide, if arsenic is present in the substance.

IDENTITY OF SCAMMONIN PREPARED FROM THE ROOT OF CONVOLVULUS SCAMMONIA. WITH THAT OBTAINED FROM ALEPPO SCAMMONY.*

BY PROFESSOR H. SPIRGATIS.

Some time since† the author published an account of an investigation of the chemical constitution of scammonin, the resin of *Convolvulus Scammonia*, Linn. The scammonin used by him on that occasion was obtained from so-called Aleppo scammony,—*i.e.*, the milky juice of the above-named plant hardened in the air,—the latter substance being at that time the only material containing scammonin that could be supplied. But as at the present time the root itself of *C. Scammonia* comes into commerce from Asia Minor, and as the German Pharmacopœia requires that the officinal Resina Scammoniæ should be prepared from it, the author considered it desirable also to prepare scammonin direct from the root, and to compare it with that formerly prepared by him from scammony. This inquiry seemed to him to be the more desirable since it has been affirmed that the two bodies are not identical.

The scammonin was prepared from the roots in the ordinary way, by exhausting them with water, removing the resin with spirit, decolorizing the alcoholic solution with animal charcoal, distilling off the spirit, and repeated washing of the separated resin with hot water. Professor Spirgatis was not able to observe any difference between the scammonin so prepared and that previously obtained from Aleppo scammony, some of which he had still in his possession. Both bodies are amorphous, colourless, transparent, without smell or taste, presenting the same phenomena in combustion, and presenting also precisely the same behaviour to solvent and chemical reagents, such as alcohol, ether, chloroform, petroleum, oil of turpentine, acetic acid, concentrated sulphuric acid, caustic potash and soda and their carbonates, ammonia, and in alcoholic solution with acetate of copper, acetate of lead, nitrate of silver and chloride of iron.

Finally the scammonin prepared from the root, dried at 100° C., gave in three experiments the composition—

* *Neues Repertorium für Pharmacie,* xxiii., 260.

	1.	2.	3.
C	56·62	56·59	56·62
H	7·75	7·70	7·88
O	—	—	—

Whilst a fresh combustion of some of the old resin under similar conditions gave, as on the former occasion, the figures—

C	56·60
H	7·76
O	—

The author considers it, therefore, unquestionable that the scammonin prepared direct from the root is identical with that formerly prepared by him from Aleppo scammony.

THE MUTUAL RELATIONS OF DRUGGISTS AND PHYSICIANS.

BY DR. C. E. BUCKINGHAM.

(*Concluded from p.* 45.)

Another picture of the way in which meanness can be shown, and in which its dangers might be shown, is in the substitution of drugs. There are shops at which you can find anything you may ask for, even if it is not in the shop. Some years ago, having just risen from a sick bed, being taken with vertigo in the street, I stepped into a drug store, where I was not known, and took a seat. Not wishing to intrude without making payment, I asked for a chemical preparation; was told that they had it, and, after a long hunting about, a package was made up for me and paid for. When I got home, I tested it, and found it to be an entirely different article from that asked for, and sent it back, with my compliments to the one who put it up. I never had any notice of its having been received. A short time after this, I wrote a prescription for four pills, which were made and taken. It was thought best to renew them, by the number on the box. The messenger by mistake took the box to that same shop Eight pills were put up in place of four, and an active cathartic would have been taken in place of a narcotic, if the patient had not seen the box and its contents before the pill was put in some jelly for him to take.

Twice within a few weeks, I have had sugar-coated quinine pills, made by machinery, sent to patients in place of pills of quinine and hyoscyamus, as directed.

It is the duty of the physician to write his prescription plainly, and to put his directions for use upon the paper. It is the druggist's duty to put up the medicine precisely as directed, or not to put it up at all. If there be anything directed which he has not, the druggist has no right to substitute anything else without consultation with the prescriber; and this, whether the articles be inert or active, whether they be costly or cheap. You have no right to think that a sulphate or an acetate will answer the purpose as well as a muriate. You have no right to add more acid to a mixture than is directed, even if it be necessary to make a perfect solution; and even in so slight a matter as an excipient, you violate your duty, if you make the simple substitution of one dry powder for another, or one mucilage for another. If the mixture be vile in its appearance, absurd in its composition, a liquid when the ignorant prescriber thought it would be dry, that is a blunder which it is not your business to correct. You might, in courtesy, notify him of the fact, but you have no right to change the mixture. You do not know, and cannot know, why a particular article is prescribed. This peculiar fault, peculiar impudence, if you please, is so common at one very popular drug store in this city, that for a couple of years past I have invariably cautioned patients not to have my prescriptions put up there.

Neither has the druggist the right to suggest to the purchaser that the dose prescribed is too large or too small. Within a very short time, a timid, nervous young lady, suffering from hæmorrhage from the lungs, and being miles from her physician, who had sent the prescription, accompanied with written directions for its use and his name appended to it, was frightened into long and dangerous neglect of herself by a druggist, who informed her that fluid extract of ergot, the best article known to-day for the prevention of hæmorrhage, is a slow poison and dangerous to use.

On the other hand, I contend that physicians have no right to prescribe unusually large doses of so-called poisons without intimating, in some way, upon the prescription, that they are aware of what is written. Should I write for half a grain or larger doses of morphia, I consider it my duty to write upon the prescription that "I have read over this prescription, and it is written as intended." Should I write for a medicine not often used, and about which there might be a mistake made, it is my duty to write down its other name also, if it has one, that the druggist may be sure of the article written for. Chloride of mercury should never be abbreviated, so that its identity with chloral hydrate may be questioned; and croton chloral should be so manifest upon the prescription that croton oil should not be substituted for it, when repose is intended as its effect.

With the best of care, every man is liable to make mistakes. Loss of sleep, or an attack of indigestion, either of these may make you or me commit an error. Under such circumstances, I have found it my duty and pleasure to thank the druggist's boy for bringing me a prescription to be completed.

The wisest course for me is to keep a copy of every prescription that I write. Copying it makes me more likely to see an error. The proper course for you is to read over the prescription, and if it is to be copied, copy it then, before it is put up. The plan of delivering up the original to him who presents it is a bad plan. In case of doubt as to the author of an error, whether it be the writer or the compounder, the evidence of the original prescription should be in your hands for your protection. He who dispenses should have the writer's authority at hand for easy reference.

There is one matter of interest to all of us, and to the public as well, which I am not sorry to have an opportunity to allude to. I refer to the habit which some druggists have of prescribing. "Well," say you, "if a man calls on me to give a dose of medicine for diarrhœa, or constipation, or cough, or sore-throat in a child, why should I not give it to him? Why is not my prescription as good as that of any old nurse, or any other neighbour who has strayed in?" It is exactly as good, and no better. The sore-throat, of which you know nothing, may be the result of insufficient dress, or of almond candy. The diarrhœa may be the beginning of a typhoid fever, or from want of flannel drawers. The constipation may be owing to too little food, or approaching disease of the brain. All of them may be simply symptoms of dyspepsia. One dyspepsia may require an acid, another an alkali; one needs a dose of physic, another requires food; one wants out-of-door air, and another a warm bed. One needs to have the patient stop his head-work, and another would be benefited by any change from his present style of life. Cough may have its cause in the head, in the throat, in the lungs, in the stomach. The very medicine which you give, without knowledge of the particular patient, and how to examine him, may be the means of aggravating the disease.

To say that this medicine is very simple, and, if it does no good, cannot do harm, is one of the most common of mistakes. If no other harm is done by it, there may be serious loss of time. But what is a simple remedy? You, perhaps, will say, "Tolu, ipecac, castor-oil, salts, rhubarb." Neither of these is so simple as morphia, or strychnia, or Prussic acid. The simplicity of an article or of its combinations has nothing to do with the usefulness or the hurtfulness of a medicine. If a man asks you for a compound cathartic pill, or for a dose of paregoric, that is all very well. I know of no reason for refusing him. If he asks you what the best cathartic for him is, or what would do his cough the most good, that is a very different matter. You know, and can know, nothing about it. If one man's meat is another's poison, and this is literally true, the parallel comparison will hold equally good concerning medicines.

The effect of the same medicine upon different individuals is very remarkable. And this cannot be wondered at by those who have seen the effect of different articles of food. Some of us know that so pleasant a fruit as the strawberry will produce difficult respiration in some who eat it. The clam and the oyster have similar effect upon others; and I have known the eating of poultry to do the same. Even the passing near enough to inhale the odour from a wheelbarrow of lobsters, I have seen followed by asthmatic breathing, and an eruption which could not be distinguished from erysipelas. So an opiate stimulates one and depresses another.

I have a case on my books, which is a fair but ludicrous illustration of the value of such prescriptions as are "simple, and can't do any harm." I was called to see a little girl, who had been kept at school on Saturday till after her usual dinner hour. When she got home, vexed and tired, notwithstanding she had a slight headache, a slice of beefsteak would have relieved her. The headache led the mother to give a dose of castor-oil, and to offer gruel, which was refused. Sunday, no improvement, and tincture of rhubarb was taken. On Monday, no better; senna and salts. Tuesday, no better, and a dose of elixir pro. On Wednesday afternoon I was called in and informed by Mrs. —— that, having no other medicine in the house, she had given the little girl an emetic, and it had brought up a great deal of bile, and she feared the child would never recover. The advice given was to feed the child and let medicine alone. Yet these were all what are called simple medicines. With the exception of great weakness and loss of flesh, the child was in her usual health in twenty-four hours.

This case is a fair illustration of the value of prescriptions made at random, and although you might not be foolish enough to go through so long a list, why should you not? If not competent to examine the patient, you are not competent to prescribe for him; and if it would be improper to continue prescribing ignorantly, so it would be improper to begin. Remember that many diseases have common symptoms at times, and it is only after days of suffering, in some cases, that the real nature of the disease is declared. The medicine which might be of service in a pleurisy or pneumonia, would be absolutely injurious to an overloaded stomach; still, the case is by no means uncommon in which chest pain, or irregular action of the heart, originates in indigestion. The delirium and exhaustion, which seemed to foretell death, has, perhaps, originated in a roasted partridge. The apparent paralysis is not infrequently the effect of liquor. Not infrequently, on the other hand, men have worn the name of drunken sot, when an early autopsy showed that disease of the brain had existed for no little time. I knew one of your profession to be the means of sending a patient to a smallpox hospital, whose eruption was caused by the balsam of copaiba which the druggist had prescribed. The simple medicine does harm, if you do not know how to use it; and, if in no other way, it may produce harm by taking the place of that which might have done service, and the use of which has been put off too long.

Another matter occurs to me, which was worth speaking of. Not that any of your number is likely to err in this way, for no gentleman can act otherwise than as a gentleman; but you may have those in your employ to whom a word of caution may be useful. No one but the patient or the writer of the prescription knows for what purpose the prescription is written. A look at the patient, as if there were the shadow of knowledge in regard to the disease, is an insult. The slightest intimation of suspicion that one knows for what disease a particular remedy is prescribed, entitles the seller of the drug to be kicked out of his own door. Yet I have known a druggist to insinuate to a modest girl, to whom copaiba was given for a cough, that he knew for what other disease it was used; and to another, that ergot was not always given to *check* hæmorrhage.

And still another word. The drug store is not the proper place for a news-room. It is no place for unemployed physicians to gather in and talk over the political affairs of the day. It is no place for medical or other loafers behind the druggist's counter. No one should be allowed there except upon business. No one should be allowed to speak with him who is weighing out and measuring medicines; and if your visitors do not know this, it would be as well to say it in unmistakeable language, or, which would be better, perhaps, to have the compounder of medicines closeted by himself alone.

And now, gentlemen, having said what has occurred to me during the short time which I have been able to spare for the purpose, if I have given you anything which you consider of any value, I shall feel very well satisfied. If these matters appear to you to be of comparatively little consequence now, the day is coming when some of you will appreciate them. It is impossible that science can be held back, and in any business where a head is wanted, as well as a hand, there must be progress. See to it that your labour does not retard it.

BROMIDE OF IRON AND ITS PREPARATIONS.*

BY M. PRINCE.

According to a calculation based upon the chemical equivalent of bromine compared with that of iodine in combination with iron, the author was induced to try the following formula:—

Unoxidized Iron Filings	100
Distilled Water	768
Bromine	210

After having introduced the iron fillings and the water into a vessel having a capacity of about two litres, 40 or 50 grams of bromine were added, and the mouth of the vessel promptly stopped with a good cork, in order to avoid loss of the latter, which escape quickly in reddish-yellow vapours due to the development of heat when the first portions came into contact. These vapours disappear and are replaced by others of a violet colour, which, like the former, only last a few seconds. A fresh portion of bromine was then added, and this operation was repeated until all the bromine had been used.

When this was effected, the whole (including the excess of iron contained in the solution, which is indispensable to its preservation,) was transferred to a stoppered bottle.

The first operation being completed, the author sought to ascertain whether the solution so obtained contained the estimated quantity of protobromide of iron. Thirty grams were filtered and rapidly evaporated to dryness, when it yielded one-third of its weight of the anhydrous salt. The author, therefore, gave it the name of normal titrated solution of protobromide of iron, and has used it in three different preparations, of which the following are the formulæ:—

Bromide of Iron Lozenges.

Normal Solution (filtered)	18 grams.
Powdered Gum Tragacanth	1·50 „
Finely Powdered Sugar	100·50 „

Evaporate the solution in a porcelain capsule to half its weight (9 grams); pour it then into a marble mortar, add the gum previously mixed with a small quantity of the sugar; after mixing, add the remainder of the sugar and bray the paste well. Afterwards spread it out upon a

* Extract from a paper read before the Society of Pharmacy at Lyons (*Bull. Soc. Pharm. Bord.*, vol. xi., p. 138).

marble slab, and divide it into lozenges weighing one gram each, which should be dried promptly and put in a dry place. Each lozenge will contain five centigrams of protobromide of iron.

Bromide of Iron Pills.

Normal Solution (filtered) . .	12 grams.
Iron filings	0·10 „
Powdered Gum Arabic . . .	q. s.
Liquorice in Powder	q. s.

To make 80 pills.

Pour the solution with the small quantity of iron into a porcelain capsule, and evaporate quickly until the liquid has lost two-thirds of its original weight; then pour it, still warm, into a well-dried and slightly-warmed porcelain mortar. Add at the same time the two powders previously mixed and in sufficient quantity to form a consistent pill mass, which should be divided equally into eighty pills, and kept in a well-stoppered bottle sheltered from damp. Each pill will contain 5 centigrams of the protosalt.

Syrup of Bromide of Iron.

Normal Solution (filtered)	12 grams.
Syrup of Gum and Orange flowers . .	620 „

M. S. A.

This quantity will represent a demi-litre of syrup containing four grams of protobromide of iron, or 20 centigrams of the active principle to each 31·60 grams of the syrup.

REMARKABLE POLYPORUS FROM CANADA.*

BY SIR R. CHRISTISON, BART.

A short time ago I came accidentally upon a mysterious specimen—mysterious, I mean, to myself—which I had put aside in 1843 till I should receive farther information about it, and of which I had lost sight during other and very different pursuits. The label on it bears that it is "a fungus from the White Pine" of Canada, presented to me by Dr. James Johnston, at the time Assistant-Surgeon in the 71st Highland Light Infantry. On presenting it to the Botanical Museum, I found that it seemed as novel and strange to Dr. Balfour and other experienced botanists as it was to myself; but a small fragment, evidently of the same kind of substance, was subsequently found in the collection of the garden.

As a cursory examination proved it to be an object of interest, I applied to Dr. Johnston for farther information; and fortunately, considering the long period which has elapsed since he parted with it, he was able to turn up in a memorandum-book the following note, taken on April 28, 1841, when he got it at "Penetangingshine, Georgian Bay, Lake Union," viz., "Bought a Wahbodo—Indian Rhubarb—a fungus growing on top of White Pine—very scarce—thirty-three years' growth. Indians say it lives—cries like a child—bleeds when wounded—and does not fall unless killed. This specimen was brought down by three rifle-balls. A tonic bitter, recommended as an application to wounds. It was brought to me from a distance of upwards of 50 miles."

The Wahbodo is still in a state of perfect preservation, as when I got it thirty-one years ago. It is 18 inches long, from 22 to 26 inches in girth, firm in external texture, and very fibrous, the fibres longitudinal. It is very white. It weighs thirteen pounds. It is strongly marked by thirty-three parallel rings, or seems to be made up of so many circular superimposed cakes, somewhat more than half an inch in thickness. At one side of its thicker end there is attached, over a space as large as the palm of the hand, a quantity of the outer bark of a smooth-barked pine. On cutting out with the saw a quarter section along its whole length, it was found that the rings outside penetrate a very short way inwards; that the texture everywhere is in general spongy, white, and fibrous; but that there are also many long, longitudinal, rudely parallel lines on the surface of the section, which are brownish, harder, not at all fibrous, and which obstructed the saw by adhering to it like a resin. The powder has a strong, pure, almost aromatic, bitter taste, very like that of sulphate of quinia.

Dr. Maclagan made a rough analysis of it for me, and found that it consists, in 100 parts, of 64·59 resin, 25·79 cellulose, and 9·62 watery extract. The bitterness he found to reside, not in the resin, but in the watery extract, and it therefore must depend on some other proximate principle, possibly crystalline.

On consulting the opinion of the most eminent English authorities on the subject of the fungi, Dr. Balfour found that all considered this substance, from an examination of small fragments of it only, to be ligneous texture degenerated and much altered by the presence of a species of Polyporus, which Mr. Berkeley thinks will probably prove to be *P. Pini canadensis* (Schweinitz).

* Read at the July Meeting of Edinburgh Botanical Society. Reprinted from the *Gardeners' Chronicle* for July 18, 1874.

THE PROBLEMS AND FUTURE OF PHARMACY IN GERMANY.*

BY FRED. HOFFMANN, PH.D.

It appears to be of interest and utility to take notice of the problems which are now being discussed in Germany, where pharmacy has been, for over two centuries, the main cultivator of natural sciences, and as such, and as a branch of the healing art, has attained a position not reached in any other country, and where not only its sphere and import, but even its very existence, seems to be at stake. Though the political, social, and industrial conditions of Germany and the other European countries differ in many respects from those of North America, it will be found that the aims and interests of pharmacy, and its relations to other trades, are the same everywhere; and for this reason the crisis into which pharmacy has entered in Germany merits a wider attention. With the radical changes of popular views, in consequence of general intellectual advancement and the popularization of all branches of physical and sanitary sciences and of rational medicine, the former state and practice of medicine, and also of pharmacy, have undergone considerable changes in Germany and in Central Europe. Although difficult to comprehend outside of Germany, the most important necessary consequence has been the removal of all restrictions formerly placed, on the part of the State, upon the practice of medicine and hygiene, in Germany as well as in Switzerland. Medicine, in consequence of its extent and its unlimited sphere of application, has separated into several parts, which, in study as well as in practice, have more or less become specialities, while some branches have become the common property of all well-educated men, and have occasionally been successfully practised also by others than physicians. Notwithstanding these innovations, modern medicine progresses; "with the higher aim that its object is not so much the cure, as rather the prevention of disease." (Virchow.) As another consequence of these tendencies the fact was lately stated, that "modern medicine has ceased to resort to and find its centre of gravity in the pharmacies." (Pettenkofer.) How far these assertions represent the reality may be judged not only from the pharmaceutical papers, but far better from the number and quality of popular science publications covering the field of hygiene and sanitary and medical sciences; the widely known popular works which have passed through many editions and translations, of Professors Bock and Reclam, of Leipzig, may be mentioned as instances.

The medical schools have sceptically discarded a large portion of the old array of remedial agents, and retained comparatively few substances of certain chemical composi-

* Reprinted from the *American Journal of Pharmacy* for July.

tion, and hence proportionable with exactness; these are more and more administered by subcutaneous injection or in minute concentrated doses, and in forms which are more handsomely prepared by the confectioner than the apothecary, while the preparation of the chemicals has been transferred from the laboratory of the latter to that of the manufacturer,* so that the sphere of the apothecary has been materially narrowed and simplified, and a chemical knowledge, though always desirable, is not in the same degree requisite as heretofore.

When, therefore, we hear of a decline of pharmacy and of a decrease of its efficiency in Germany and other European countries, as yet not a degeneration of pharmaceutical education and proficiency nor of the status of pharmacy is intended, but principally the reaction of the conditions briefly sketched above upon pharmacy. An increase of medical scepticism and a lessening in the public mind of the value of remedies must certainly be followed by the lowering of the importance of pharmacy. Medicine cannot well be subject to such a retrogression, because its successful practice lies in an unalterable path, concerning the instability of human nature and life, and presupposes, besides actual knowledge, an individual fitness, technical skill, experience and judgment, with which the educated physician can always successfully encounter the ignorant or half educated competitor, while the competition amongst pharmacists scarcely exists upon the scientific, but almost exclusively upon the mercantile, field.

The future status of pharmacy in Germany, as influenced by these factors, and in consequence of the rapid intercourse of nations and the generalization of ideas, their influence upon pharmacy in other countries has been for some time the subject of deliberations in the pharmaceutical journals and in the meetings of pharmaceutical societies. To this must be added the pending abrogation of the protective grants, an institution antiquated in its origin and nature, but which has been one of the most important factors through which German pharmacy has reached its high status and its pregnant co-operation in the advancement of the physical sciences. The nature of these grants has been explained by me in a former paper, entitled "Pharmacy in Prussia and the German Empire."† Latterly, besides many reforms in relation to arts and industry, the grants and concessions have been abolished, and since the release of the practice of medicine, that of pharmacy appears to be merely a question of time and a financial problem, the solution of which is attended with so many difficulties, because upon these grants large amounts have been invested, which, with the legal abolition of the former, would be lost as far as they exceed the real value of the business. This question of national economy, which is now being discussed and is under consideration before the Government and the Legislature (Reichstag) in Germany, has been apparently satisfactorily solved in Sweden in this manner, where every newly established pharmacy has to contribute a certain sum, in accordance with fixed principles of valuation, towards the redemption of the capital invested in pharmacies, as far as its value is lessened in the same place. It is probable that a similar way will be chosen in Germany for the inevitable solution of this problem.

These are, in brief, the principal causes of impediment to the progress and prosperity of pharmacy in Germany, and which have tended to keep talent and capital from being invested in pharmaceutical pursuits, and to induce many young and promising pharmacists to leave their chosen avocation for others more remunerative.

Among the recent publications on this subject, those of three pharmaceutical authorities, equally prominent by experience, knowledge and standing, have attracted a wide attention, namely those of Professor Dr. Phoebus, of Giessen,* of Professor Dr. Hlasiwetz, of Vienna, and of Mr. W. Danckwortt, of Magdeburg, formerly Chief Director of the North German Apothecaries' Association. The following synopsis of the remarks of the two last-named men may serve to elucidate more fully their views of these vital questions and their bearings upon the future of pharmacy in Germany.

Prof. Hlasiwetz, formerly an apothecary, now Professor of the Imperial Polytechnic School of Vienna, in a recent lecture on Modern Pharmacy,"† said in substance:—

"Until recently, chemistry had its ablest and most useful representatives among the pharmacists, and for a long time this profession has pre-eminently supplied the chairs of chemistry of the universities with professors to whom we owe the vast amount of labour and discoveries which were necessary to bring practical and theoretical chemistry to its present scope and position. But this has greatly changed by degrees, the consequent rapid progress has called forth a chemical industry of the most varied description and extent, which, in its rapid strides, has substituted the methods of manufacturing on a large and commercial scale for those on a small scale in the laboratory of the pharmacist. This change in the scope and drift of pharmacy has deprived the pharmacist of one of the principal objects and profits of his legitimate business, and since the fact has become fully established that he cannot enter into competition with the manufacturer, either in regard to quality or price, there is nothing left to his share than to dispose and retail the products of the former. Not only the whole series of medicinal chemicals and alkaloids are now supplied by the manufacturer cheaper and, as regard the latter substances, better, but also those pharmaceutical preparations which belong pre-eminently to the province of the pharmacist; as, for instance, fluid extracts, tinctures, syrups, ointments, plasters, etc.

"Since the inauguration of this sweeping change dates the decline of the so-called pharmaceutical chemistry, and all that the pharmacist yet applies is a moderate degree of analytical skill for the establishment of the identity and quality of the preparations as supplied by the manufacturer. And even this limited sphere of proficiency is encroached upon by the manufacturers, by offering on the labels of their preparations brief instruction, for ready tests, and by supplying pure and ready made reagents, so that the tests may be made by any skilled and informed person.

"Our schools and universities still furnish a sound pharmaceutical education and a stock of chemical knowledge; but the truth is that these attainments, as a rule, do not bring fruit, for the reason that pharmaceutical practice has ceased to afford any longer the former compass and opportunity of application, or a sufficient impetus to practically cultivate the acquired proficiency.

"Moreover, the advanced state of rational medicine has discontinued the use of many remedial agents, and has greatly limited not only the list of materia medica, but also the former liberal administration of medicines; the consequence of this restriction is a decrease of the legitimate business and income of the pharmaceutist; being formerly a remunerative pursuit, it hardly furnishes, any longer, a respectable living to a great many highly educated men, and we see, therefore, the pharmacist enter more and more upon mercantile resources for subsistence. With the aim to gain, on the other hand, as a dealer, what the professional scope of his business falls short to supply, he enriches his stock with homœopathic and with patent medicines, and enters into competition with the dealer in fancy articles, with the perfumer, the confectioner, etc.

"The business of the pharmacist depends for the

* See synopsis of lecture in *Druggists' Circular*, 1874, March, p. 57; and *Pharm. Journ. and Trans.*, March 28, 1874, p. 781; also Prof. Redwood's lecture on the "Past, Present, and Future of Pharmacy." *Ibid.*, April 25, 1874, p. 852.

† *Pharmac. Zeitung*, No. 8, 1874.

future largely upon the drift of the manufacturing business, which, when it should also extend its aim and scope to the production of the medicinal substances in ready-dosed and elegantly-prepared forms, will deprive the pharmacist, more or less, of the last remnant of his proficiency. This inroad has already commenced, and bids fair way to an increasing extent and to success; it tends to relieve the physician from the necessity of prescribing so many grains of Dover's powder, of quinia, of calomel, etc., to be rubbed up with sugar and divided into so many doses; he will merely have to direct his patient to buy a number of dosed capsules or tablets. He will soon find all the chief formulæ of his dispensatory provided in elegant forms and envelopes, disguising smell and taste, and both the physician and the patient will gladly dispense with the old, repulsive forms of mixtures, decoctions, powders, etc. The great number of vegetable drugs of uncertain value and variable quality will be discarded, and will be replaced by the active principles, obtained from them in a pure and stable form, so that the materia medica of the rational physician will henceforth be like that of the homœopathist, ready prepared and dosed, and all emanating from the manufacturing establishment.

"When system and method will extend and consummate this mode of administration of the remedial agents, nothing will be left of the pursuit of the pharmacist than a retail dealer of the products of the manufacturer of medicinal articles."

Mr. W. Danckwortt expresses himself in an article "On the Future of Pharmacies,"* thus:—"I believe that after forty years pharmacy will have greatly changed its physiognomy; I do not entertain pessimistic views, and consider it an honour to have served for forty years in a profession which I esteem highly, but when I compare its present condition and prospects with those of forty years ago, I cannot but admit that pharmacy is on the decline and will henceforth degenerate far more rapidly. But thirty years ago chemistry and botany were pre-eminently the sciences of the pharmacist; Berzelius, H. Rose, Liebig, Fresenius, Berg, Henkel, Mohr, and many others of equal fame, emanated from pharmacy. Nowadays, chemistry has grown in extent and volume so vastly, and its practical application embraces such a wide compass, as completely to leave behind the pharmacist's sphere. Yet the pharmacist has maintained a comparatively high status of chemical knowledge and learning, and a comparatively wide compass of attainment is still required from him. But the fact is that these accomplishments have to be attained mainly to enable him to pass the examination which the State makes yet obligatory; after this, he has not any more the old arena to practically apply and profitably enlist his attainments, nor the former impetus, so that, in many cases, the knowledge acquired at the universities is gradually lost for want of application and encouragement. Formerly, the pharmaceutist used to be the legitimate expert in all forensic investigations: now the extent of knowledge and experience required are such as to exclude him in preference of the professional chemist. The pharmaceutical laboratory of yore has become a myth, and we must admit that most of the medicinal chemicals and pharmaceutical preparations can be obtained cheaper and better when manufactured on a large scale; many of them are now furnished by the manufacturer already dosed and labelled for ready dispensation and retail sale. And when we compare the prescriptions of our days with those of forty years ago, what a change, what a remarkable simplification! The whole array of the old-fashioned decoctions, infusions, and mixtures have been discarded; morphia, codeia, quinia, digitalin, chloral-hydrate, atropia, and a number of other principles, are the consummation of materia medica, and even the prescriptions for these disappear more and more from the pharmacies, inasmuch as the physician carries their minimal solutions in his pocket for ready administration by subcutaneous injection, or orders them in tablets or sugar granules as supplied by the manufacturer or confectioner in lieu of the pharmacist.

"Moreover, the rapid progress of general culture, of the knowledge of the rational principles of life and health, and the conditions of their maintenance, of the sanitary sciences and of hygiene and medicine, exercise a considerable influence upon the decrease of the use of medicines, for it cannot be denied that knowledge and culture counteract the principles and conditions upon which, to a great extent, the prosperity of pharmacy rests.

"When we have witnessed such changes within the comparatively brief space of forty years, who has the assurance to predict what, or if anything, will be left of pharmacy after another equally progressive lapse of forty years?"

(*To be continued.*)

THE REPORT OF THE SELECT COMMITTEE ON THE APOTHECARIES' LICENCES (IRELAND) BILL.

Although the report of this Committee has been presented and ordered to be printed, it had not at the time of our going to press been yet published, but it will probably be issued within a few days. Meanwhile, by the courtesy of a correspondent, we are enabled to give an extract from the letter of the London correspondent of the *Freeman's Journal* of July 21, which professes to give the conclusions arrived at by the Committee, though upon what authority the report of the Committee is thus anticipated we are unable to gather from our Irish contemporary.

"Mr. Errington's Apothecaries' Licences Bill Committee have to-day decided upon their report, of which I am able to give you a *résumé*. Admitting at the outset that a Pharmaceutical Society for Ireland is much required, and that the country possesses ample material for the constitution of such a body, the Committee recommend that the Government should introduce a bill (in lieu of Mr. Errington's original bill) empowering the Lord-Lieutenant in Council to appoint, in the first instance, a certain number of foundation members, who shall form the nucleus of, and draw up rules as to qualifications, examinations, etc., for an Irish Pharmaceutical Society. Such society, when constituted, shall be a perfectly independent body, on a footing equal to the English society, possessing co-ordinate and reciprocal powers with the latter body—that is to say, that while itself independent, members of the English society may practise in Ireland, and members of the Irish body may practise with equal rights in England and Scotland. The new Society will be formed mainly on the basis of the English body, and members of the Governing Council will be elected for three years. With regard to dispensary chemists, the Conservative members of the Committee carried a resolution recommending that in future licences should be required for the compounding and sale of poisons, but by the action of the Liberals a suggestion is made by which those now compounding and dispensing poisons need not take out licences, but that this system shall apply to such chemists as may hereafter wish to dispense such articles. When the report has been presented you will be able to publish its *ipsissima verba*, but it may be added that the bill recommended by the Committee will not be introduced until next session."

The Pharmaceutical Journal.

SATURDAY, JULY 25, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE HOURS OF LABOUR IN PHARMACY.

WE noticed that one of the signs of improvement among pharmacists which attracted the attention of Señor KYLE, during his recent visit to England, was the shorter time daily during which many of them now keep their establishments open. This is in accord with the opinion expressed by the Council of the Pharmaceutical Society in its last Report, that "recently the early closing movement has spread among chemists." But, however gratifying it may be to read these statements, it is subject for regret that the improvement is as yet only a partial one, and it is evident that further efforts will be required before it reaches that degree of prevalence with which pharmacists and their assistants will "rest and be thankful." In the belief that former discussions in this JOURNAL have contributed towards smoothing the path of this reform, its columns have again been opened to one of those bursts of correspondence which are periodically excited by this subject.

Although the questions of the charges which pharmacists should demand from the public, and of the salaries they should pay their assistants, are invariably raised in this discussion, we prefer not to deal with them here, believing that their settlement in each case depends too much upon the individual estimate of the seller as to how much he can get for what he has to sell, and of the buyer as to the price at which he can afford to buy, for such settlement to be ever permanently affected by *ex cathedrâ* utterances.

But the number of hours during which pharmacies should be kept open is so purely a matter in which the interests of employers and assistants perfectly coincide, and, under proper arrangements, are not in conflict with those of the public, that with a body like the chemists and druggists, which, although large, is limited by registration, there must be a possibility of reducing the time of business within reasonable limits. We thoroughly endorse the opinion expressed by the President, Mr. T. H. HILLS, at the Annual Meeting of the Society, in May last, that pharmacists have inflicted these long and tedious hours upon themselves, and that it will be their own fault if the evil is not rectified.

But how? In the first place, it is essential that every member of the body should intelligently recognize the existence of the evil as well as the necessity for its removal, and of himself doing something more than grumbling and bearing it. The acknowledged variation of the circumstances attending the business in different neighbourhoods probably renders adherence to any hard-and-fast line impracticable; but this indicates the necessity for local efforts to arrive at an understanding, rather than that further improvement is hopeless. We think that Mr. CARDELL gives sound advice when he says, "Let some one who takes real interest in the trade, and in the welfare of those engaged in it, canvass the town or neighbourhood in which he lives, and ascertain what the majority wish to be done." We would add to this the expression of a hope that, where such work is undertaken, the volunteer canvasser may not be "assisted" with objections, but may meet with the hearty help and sympathy of those whom he visits.

We are sorry to note that some of our correspondents appear to look to the Legislature as the Jupiter to help the waggon out of the rut. For while respecting the motives of Sir J. LUBBOCK's Bill, and admitting that the principle of State control of the hours of labour has been beneficially applied in factories, we believe that the ever-fluctuating conditions and needs of a retail business would render such interference intolerable, and moreover that it would be evaded by innumerable subterfuges. Neither are we disposed to look with more favour upon the proposal to establish such a Society as suggested by one or two of our correspondents. It could not be hoped that any Society would include nearly all the employers and assistants in the trade; there would probably always be a large proportion of non-members who would ignore or refuse to be controlled by its regulations, and, even if it had more than an ephemeral existence, that would probably be due to its drifting from the purpose for which it was originally formed, into the trades-union, either of employers or employed, which has been generally deprecated.

At any rate, before resorting to such extreme measures, we think it is desirable that a vigorous and sustained effort should be made with the weapon we have at hand,—the exertion of individual personal influence and example.

THE MEETING OF THE MEDICAL COUNCIL.

THE session of the Medical Council, which terminated on Saturday last, was, of course, mainly devoted to business too medical in its bearings for detailed description in these columns; but some few incidents involved a wider interest, and such were those which referred to the British Pharmacopœia and the Adulteration Act.

Dr. PAGET, the President, in his opening address, alluded to the compiling and publication of the "Additions to the Pharmacopœia" as work done since the last meeting, and mentioned that a Report would be presented by the Pharmacopœia Committee. Before that Report was presented, however, a motion on the subject was brought forward by Dr. A. SMITH, embodying a series of fourteen propositions. Their purport was that a Committee of five members should be appointed to prepare a new edition of the British Pharmacopœia, to be ready for publication in January 1877, and that the Medical Council should appoint three of the members of that Committee, and request the Council of the Pharmaceutical Society to appoint the other two, who should be associated, on equal terms, with those appointed by the Medical Council. This Committee was to be authorized to prepare three lists, (1) of such articles and preparations in the British Pharmacopœia as ought to be expunged; (2) of such preparations in the Pharmacopœia as might be modified with advantage; and (3), of articles and preparations to be introduced. It was also to be empowered to employ a chemist, from time to time, to make such investigations as might be deemed necessary. The lists were to be submitted "for discussion in the Pharmaceutical Society, etc., in order to ascertain the opinion of all branches of the profession respecting the propositions of the Committee." The proposed Committee were to make all the corrections deemed necessary for the new edition, subject to the approval of the Medical Council. Dr. SMITH, in support of his motion, said that there was a general feeling that in this country, as in the United States, there should be an edition of the Pharmacopœia published every ten years, and that if so it was not too soon now to enter upon the matter. The motion, however, fell to the ground through not being seconded, after Sir W. GULL had expressed an opinion that it was premature, because, before 1877, "*fui*" would apply to many a now popular remedy. A letter from the Council of the Pharmaceutical Society, enclosing the resolution passed at its last meeting, was afterwards read, but no motion was made respecting it.

The Report of the Pharmacopœia Committee stated that five thousand copies of the reprint of the Pharmacopœia, including the Additions, and ten thousand separate copies of the Additions, had been prepared at a cost of £738 18*s*. 6*d*.; of these nearly one thousand of the former and six thousand five hundred of the latter had been sold, realizing £376 13*s*. 6*d*., and leaving on hand a stock valued at £891 16*s*. The Report recommended that the Pharmacopœia Committee should be re-appointed and consist of five members. This was agreed to, and Drs. QUAIN, BEGBIE, BENNETT, SHARPLEY and SMITH were chosen. Upon the motion of Sir D. CORRIGAN, a resolution was passed requesting the attention of the Committee to the "desirability of correcting, in any future edition of the Pharmacopœia, the approximate solubilities of salts and other substances, under characters and tests, instead of the present indefinite information afforded." Sir D. CORRIGAN said that he experienced occasionally great difficulty in prescribing, on account of the solubility of salts not being fully stated.

A Report from a Committee appointed to consider the Report of the Select Committee of the House of Commons on the Adulteration Act in connection with qualifications in State medicine and public health, was received and adopted. The views of the Committee were set forth in a series of resolutions to the following effect:—

(1) That no one should be eligible for the office of public analyst unless he be possessed of a certificate granted by an examining board of competency in analytical chemistry, in the use of the microscope, and such other subjects as the Medical Council shall from time to time determine, or a qualification as an officer of public health, which shall include these subjects. (2) That the office of public analyst may be held separately, or in conjunction with that of an officer of health. (3) That it is desirable that the granting of such qualifications should not be confined to any single examining board, but that one or more examining bodies for that purpose should be established in England, in Scotland, and in Ireland. (4) That the Medical Council should have authority to define the course of instruction and the examination required for the said purposes, and to publish a list of the bodies which comply with the conditions laid down. (5) That it is desirable that it should be made lawful that the qualifications of public analyst and of officer of health should be entered on the Medical Register as additional qualifications when the holder is already a registered medical practitioner.

It was resolved that a deputation from the Medical Council should be appointed to obtain an interview with the President of the Local Government Board for the purpose of conferring on the subject of the above resolutions.

MR. SIMON'S ANNUAL REPORT ON THE PUBLIC HEALTH.

WITHIN the last few days, the report of Mr. SIMON as Medical Officer of the Privy Council and Local Government Board has been issued. Notwithstanding that the year 1873, to which it refers, was a "period of official and administrative transition," consequent upon the Acts of Parliament of 1871 and 1872, which militated against a comprehensive report on the subject, it contains much valuable matter, not the least important being a sketch of the purpose which Mr. SIMON thinks the reports under the Act of 1858 must in future be expected distinctively to fulfil. Mainly, this is the exposition of the knowledge which the Local Government Board, through its department of sanitary inquiry, obtains with regard to the practical effect of the laws which are in force for the prevention of disease throughout England.

The year is especially noteworthy in that, by the appointment of health officers under the Act of 1872, the medical profession, for the first time, was brought into official use with a view to the better prevention of disease. Several local inquiries were made in cases of much sanitary interest, and others have been devoted to an examination of the sanitary conditions under which certain industries are now carried on. The steps taken to ward off the approach of Asiatic cholera, which in the latter half of the year 1873 was prevalent in many parts of the Continent, are referred to, and it is stated that three times in the Thames, twice at Liverpool, and once at Swansea, the local arrangements were tested by infectious arrivals. One of these cases will illustrate what London probably owes to the prompt action of the health authorities. A ship from Hamburgh landed at Blackwall 82 emigrants in destination for New Zealand, apparently in good health. Immediately afterwards, whilst waiting reshipment in some lodging-houses in Whitechapel, it became evident that cholera was among them. Notice having been given by a local practitioner, the health officer of the port, Mr. Henry Leach, with the co-operation of the emigration agent, had the emigrants collected and isolated on board the hospital ship "Rhin," where the disease developed in 28 cases, and there were eight deaths.

We notice that nothing is said in this Report as to the relation of the Adulteration Act to the public health, and it may account for some of the confusion which has attended this piece of domestic legislation that the official probably best qualified to give advice on the subject does not appear to have been consulted.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

In the week succeeding that in which the British Pharmaceutical Conference is to gather in London, the British Medical Association is to hold its forty-second annual meeting at Norwich. The proceedings are to commence with a service in the Cathedral, on Tuesday morning, August 11th, and to wind up, on the following Saturday, with excursions to geological and botanical stations and places of antiquarian and general interest, in Norfolk and Suffolk. A Museum will be formed in the Assembly Rooms, for the exhibition of the latest inventions in medical and surgical instruments and appliances, pathological specimens, new chemicals and drugs and their preparations, new articles of diet, etc. Sir William Fergusson, Bart., F.R.S., is President of the Association, and Edward Copeman, M.D., of Norwich, the President-Elect.

THE PROFESSORSHIPS AT THE YORKSHIRE COLLEGE OF SCIENCE.

At a meeting of the General Council of the Yorkshire College of Science, held last week, Mr. A. H. Green, M.A., late Senior Fellow of Gonville and Caius College, Cambridge, was elected Professor of Geology and Mining, and Mr. A. W. Rucker, Fellow of Brasenose College, Oxford, as Professor of Physics and Mathematics. The appointment of a Professor of Chemistry is to be made to-day (Friday).

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary Examination, held on the 6th inst :—

ENGLAND AND WALES.

Three hundred and twelve candidates presented themselves for examination, of whom *one hundred and fifty* failed. The following *one hundred and sixty-two* passed, and have been duly registered as "Apprentices or Students":—

FIRST DIVISION.

	Whigham, Robert Laing	Cardigan.
	Scott, Jeffers Wilson	Douglas.
	Crompton, Henry	Bury.
	Tipping, William Thomas	London.
	Thomas, John	Crosswell.
Equal.	Hern, John	Plymouth.
	White, Charles	Southborough.
Equal.	German, Frederick Francis	Burslem.
	Williamson, James	Ash.
Equal.	Beacock, Joseph Henry	Barton-on-Humber.
	Roberts, Frank Nixon	Woburn.
	Goodchild, Alfred Clarke	London.
	Crompton, Alfred, junr.	Bury.
	Pink, James Henry	Ford.
	Morgan, William	St. Clears.
Equal.	Ashton, Charles Sampson	Yeovil.
	Austin, George Leonard	Ashford.
	Parsonson, Thomas	Wath-upon-Dearne.
Equal.	Cooke, Samborne	Nottingham.
	Harding, Sarah Margaret	Birmingham.
	Goss, Sidney George	London.

SECOND DIVISION.

	Marshall, Joseph Jewison	Beverley.
Equal.	Crawley, John	Wotton-under-Edge.
	Emmerson, George John	Barnes.
	Jones, Henry	New Milford.
Equal.	Allen, Samuel	Worcester.
	Tod, John	Coventry.
	Torrance, John Turnbull	Uttoxeter.
	Jones, William Parry	Everton.
Equal.	Bush, Arthur	Barnes.
	Morris, Humphrey	Dolgelly.
Equal.	Beadle, Joseph	Stockton-on-Tees.
	Peters, Leonard George	Tunbridge Wells.
Equal.	Hunter, William Sisson	London.
	Williams, Samuel Roskelly	Devonport.
Equal.	Nason, Edward	Birmingham.
	Petter, Walter	Newport, Mon.
	Remfry, Samuel Alfred	London.
Equal.	Raynes, Sidney Herbert	London.
	Thornley, Frederick	Devizes.
	Williams, Morris James	Aberayon.
	Tozer, Frederick Early	Maidenhead.
Equal.	Barker, Charles	Taunton.
	Llewellyn, David	Cilcerin.
	Pyefinch, John	Shrewsbury.
	Shepley, Frederick Thomas	Peckham.
	Wilkins, Frank	Norwich.
	Wilkinson, William Halse	London.
	Williams, Thomas	Llwynpiod.
	Carr, John Allen	Lancaster.
Equal.	Scarborough, Henry Willson	Grantham.
	Tibbits, James Reginald	Rugeley.
Equal.	Davies, Thomas	Bridgend.
	Rees, John	Maesteg.
Equal.	Roberts, G. W.	Manchester.
	Withers, Oliver	Manchester.
	Richards, Philip	Bury St. Edmunds.
Equal.	Charters, John	Workington.
	Cordiner, Richard	Heslerton.
	Fryer, Harry	Leeds.
	Newton, Rupert William	Kenilworth.

Hodgson, Ralph, ...Brixton.
Equal. Calvert, Arthur ....Thornton.

FIRST OR PRELIMINARY EXAMINATION,

JULY 6, 1874.

Time allowed: three hours.

SPECIAL INSTRUCTIONS TO CANDIDATES.

The attention of candidates is invited to the following points:—

The method of conducting these examinations is arranged essentially for the convenience of candidates generally throughout the country.

It is, however imperative that they should be conducted with strict impartiality and honesty, and candidates are requested to comply in every respect with the required regulations, and assist the Superintendent in securing faithful results.

The least infringement may imperil not only the paper of the individual offender, but also that of every other person present.

The regulations will be read aloud by the Superintendent.

One side only of each sheet of paper is to be written on; the reverse side may be used for scribbling and calculations, but no other scribbling paper or blotting paper is allowed to be used.

In framing answers, candidates should not enlarge upon the questions, but confine themselves to giving, as briefly and clearly as they can, the information required.

LATIN.

N.B.—*Candidates are not required to translate more than two paragraphs, and are recommended to select either Nos.* 1 *and* 2, *or Nos.* 3 *and* 4.

1. Nam. etsi sine ullo periculo legionis delectæ cum equitatu prælium fore videbat; tamen committendum non putabat, ut, pulsis hostibus, dici posset, eos ab se per fidem in colloquio circumventos.

2. Qui suum timorem in rei frumentariæ simulationem angustiasque itinerum conferrent, facere arroganter; quum aut de officio imperatoris desperare, aut ei præscribere viderentur.

3. Macera per horas quatuor in vase operto prope ignem; dein Semen exime, et contunde in mortario lapideo; contusum liquori redde. Tum decoque ad octarios quatuor, et liquorem adhuc calentem cola. Denique ad idoneam crassitudinem consume.

4. Probe commisceantur. Indatur nari ex quâ sanguis stillat, turunda ex linteo raso, humectata hoc liquore et relinquenda illic per dies duos.

5. State the genitive plural of "ovis, canis, ovum, pes, flos, and urbs."

6. What cases do the following verbs take? "Oportet, pudet, curo, debeo, dico, doceo, muto."

7. Parse "Mihi negligenti esse non licet."

ARITHMETIC.

8. The charge for carrying the mails by railway to Birmingham is £28 4*s.* 4*d.* per day, how much is this in 365 days?

9. Add together $\frac{3}{5}$, $\frac{7}{8}$, $\frac{9}{10}$, and $\frac{7}{32}$ both as vulgar fractions and as decimals, and show that the results agree.

10. What is the cost of a box which measures 6ft. 8in. long, 3ft. 9in. wide, and 3ft. deep, at 1*s.* 9½*d.* per cubic foot?

11. If 18 men can dig a trench 30 yards long in 24 days by working 8 hours a day, how many will dig a trench 60 yards long in 64 days, working 6 hours a day?

ENGLISH.

12. Add *able* to change, cure, dispute, charge.
 ,, *ly* to due, safe, wide, true.
 ,, *ed* to prefer, limit, offer, fulfil, stem.
 ,, *ment* to judge, refine, argue.

13. Parse the following:—

"Man's inhumanity to man
Made countless thousands mourn."

14. Write from fifteen to twenty-five lines on one only of the following subjects:—

Printing.
Universal Suffrage.
Happiness.

Provincial Transactions.

IRISH ASSOCIATION OF CHEMISTS AND DRUGGISTS.

A meeting of the above Society was held in the Society's rooms, Molesworth Street, Dublin, on Monday evening, the 20th inst., Professor Tichborne, V.P., in the chair. Several new members having been proposed, the Hon. Secretary, Mr. Hayes, proceeded to read the evidence given by him before the Select Committee of the House of Commons. Mr. Hayes' evidence was very much approved by the meeting, and a cordial vote of thanks was passed for his zeal and energy in the interests of the Society. After some conversation on the position of the Chemists and Druggists in connection with the proposed change in the pharmacy regulations of the country, Mr. Holmes said that he had come prepared with a motion, which he thought would meet the unanimous support of the Society. The motion was as follows:—

"That this Society approves of the extension of the English Pharmacy Act to Ireland as a fair and satisfactory settlement of the pharmacy question, with these provisoes:—

"1. That all at present engaged at the business, whether on their own account or not, be entitled to register themselves as Chemists and Druggists.

"2. That all at present engaged at the business, whether on their own account or not, be allowed to compound prescriptions and become members of the Pharmaceutical Society by passing the Modified examination.

"3. That a branch of the Society be established in Dublin similar to the one in Scotland."

Mr. Greenfield had great pleasure in seconding the resolution. A conversation took place on the subject, and several of the members considering the motion premature, inasmuch as it would be better to wait and see the report of the Select Committee, Mr. Holmes withdrew the motion for the present. After some further business connected with the financial affairs of the Society, the meeting adjourned.

Parliamentary and Law Proceedings.

ALLEGED ADULTERATION OF NATAL ARROW-ROOT.
DISMISSAL OF SUMMONS.

On Wednesday, July 8, Messrs. Johnson and Woolrich, chemists, of Uttoxeter. attended at the Uttoxeter Police Court, in answer to a summons issued at the instance of Mr. M. Richards, inspector under the Adulteration of

Food Act, for having sold two ounces of arrowroot as pure, which Mr. Scott, one of the county analysts, had pronounced to be adulterated with starch other than that of true arrowroot. On a previous occasion, the accuracy of the analyst's deductions was disputed on behalf of the defendants, the certificates of three other analysts (who, the defendants alleged, had been supplied with specimens from the same bulk) being submitted, all of which stated that the article in question was pure and good in quality.

The Bench, of course, could not accept these latter certificates as evidence, but under the circumstances they agreed to the remaining portion of the arrowroot bought by the inspector being submitted to Dr. Voelcker, the analyst of the Royal Agricultural Society, Lord Waterpark undertaking to deliver the sample. Dr. Voelcker's certificate was now produced, and was to the following effect:—

"11, *Salisbury Street, London,*
"*June* 20, 1874.

"My Lord,—I beg to enclose a copy of an analysis of the sample of arrowroot which your lordship sent me. It is pure arrowroot, and, like all arrowroot, consists of starch, with scarcely a trace of gluten and mineral matter.

"COMPOSITION OF SAMPLE OF ARROWROOT SENT BY LORD WATERPARK.

"Moisture	11·28
Starch	88·69
No gluten	
Mineral Matter	·03
	100·00

(Signed) "AUGUSTUS VOELCKER."

The Bench at once dismissed the case.

ACTION AGAINST A CHEMIST AND DRUGGIST FOR SUPPLYING A WRONG MEDICINE.

At Barnstaple, on Tuesday, the 14th July, an action was brought in the County Court by William Rice, of West Buckland, farmer, against John Hames, of Boutport Street, Barnstaple, chemist, for £2, claimed as the value of a dog alleged to have been poisoned by a deleterious drug improperly supplied by defendant as medicine. The case had been before the court on two previous occasions, and was adjourned in order that an analysis of the medicine might be made. Mr. J. A. Thorne was for plaintiff, and Mr. R. I. Bencraft for defendant.

Mr. Thorne explained that the case had been brought to a standstill on the last occasion by the absence of Mr. Curtis, the chemist, who had made an analysis, but who did not wish to appear against a brother tradesman. He was now furnished with the evidence of a most unexceptionable scientific witness. The first witness was Chapple, the rural postman between Barnstaple and West Buckland, who deposed that on the 24th day of February last, after returning from West Buckland, he went into the shop of the defendant, in Boutport Street, for something for the plaintiff to cure the distemper in a dog. He had forgotten the name of the drug he was to ask for, and had lost the ticket, but it was threepenny-worth of some mineral, and defendant gave him a little packet, for which he paid 3*d*., and took it the next day to plaintiff, who, on opening it, said it was not the right thing, and gave it to him back again, with a note bearing upon it the name of what was wanted, which was Turpeth mineral. He took back the former packet, and gave it with the note to the defendant, who gave him a packet labelled "Turpeth, mineral—Poison," which he took and delivered to plaintiff next day. Some time afterwards he took the same packet, with some of the stuff in it, and left it with Mr. Curtis, druggist, on the Strand.

William Rice, the plaintiff, deposed that he received the packet brought on the second day by the last witness, and administered a portion of the contents of it to a dog which was suffering from distemper. This was on the Sunday. After taking it, the animal seemed to be in great pain, and died on the following day. It was a valuable dog, a cross between a spaniel and a terrier, and he considered it worth £2. He had administered turpeth mineral a great many times, and always with good effect until this occasion. Went to see the defendant, and asked him to pay for the dog, which he refused to do. He told him he had sent him the wrong article. Defendant asked him to show him what he had left of it, but he would not do so, although he had it in his pocket. Defendant refused to show it him, because he thought he would perhaps keep it. Afterwards submitted it to Mr. Curtis, and also to Mr. Blyth. Gave the dog the same dose he had often given before, which was about a third of the 3*d*. worth. In cross-examination by Mr. Bencraft, witness said the first packet was not properly labelled. He opened it, and saw that it was not the thing he wanted. It was a black powder, and he returned it, and sent for turpeth mineral on a written note. Had not given the dog anything else, nor sent to Dr. Jackman for anything.

Mr. Alexander Winter Blyth was then called, but declined to be sworn until he had been paid his fee, which, as a scientific witness, his Honour said he had a right to require to be prepaid. Asked what his fee was, Mr. Blyth said two guineas, and the amount was handed to him after some little hesitation. He deposed that he was public analyst for the county of Devon. On the 8th of July there was a packet delivered to him by the Rev. J. H. Coplestone, rector of West Buckland, the contents of which he was requested to analyse. It was a red powder, labelled, "Turpeth mineral—Poison." He had analysed it, and found it to be red oxide of mercury, commonly called red precipitate. Turpeth mineral was a different thing altogether. That was a sub-sulphate of mercury. Had had experience in the treatment of dogs. Turpeth mineral was a very common medicine for the cure of distemper. Both red precipitate and turpeth mineral were poisons, but he would not say equally dangerous. They might both be called irritant poisons. A very small portion of either would produce sickness, but a large dose of red precipitate would infallibly produce death.

His Honour asked Mr. Thorne how he proposed to prove that the powder analysed by Mr. Blyth was the same as sold by the defendant.

Mr. Thorne said he was in some difficulty, as the clergyman of West Buckland, who had handed it to Mr. Blyth, was not present. But he proposed to send for Mr. Curtis, who had some of the powder from the postman, and who, he had no doubt, would attend under the circumstances.

The case was deferred for a while for Mr. Curtis's appearance. On his arrival it was resumed. On his going into the box to be sworn, Mr. Thorne asked him if he also required to be prepaid his fee; to which he replied that he did not—he would "trust in Providence" for it. The witness said he had received a packet from the postman, and had examined the substance it contained, which certainly was not turpeth mineral. He analysed the powder, roughly in the first instance, and afterwards more carefully, and found it to consist of red oxide of mercury or red precipitate—altogether a different substance from turpeth mineral. Turpeth mineral was the ordinary medicine administered to dogs suffering from distemper, for which, indeed, it was a specific. Red oxide of mercury was not a proper medicine to administer: a considerable dose of it would be sure to kill. Thirty grains of turpeth mixture would be sold for 3*d*. You might administer 15 grains to a large dog, but 10 grains would be the dose for an ordinary dog, which would be one-third of 3*d*. worth. Fifteen grains would not kill. In cross-examination by Mr. Bencraft, the witness said he certainly should not sell a quarter of an ounce of turpeth mineral for 3*d*. Had never known more than 30 grains sold for that price. A dose of 15 grains would not kill. He should call turpeth mixture an irritant poison. He should say there might have been 30 grains in the packet. A third of 30 grains of red precipitate would not kill, but a third of two drachms would certainly kill in one or two days.

In answer to his Honour, Mr. Thorne said he must put aside the evidence of Mr. Blyth, and rely on that of Mr. Curtis, who received the powder from the postman's hands.

Joseph Vickery was called to prove the dog was worth £2.

This was the case for the plaintiff.

Mr. Bencraft addressed his Honour for the defence, and contended that the charge was not made out that the death of the dog arose from want of due care on the part of his client. In all probability the cause of death had been an overdose of the medicine, administered by unscientific hands. He called in evidence the defendant, Mr. John Hames, who deposed that the witness Chapple came to his shop, accompanied by another rural postman called Cowell, and asked for something, he did not know what, for he had lost the paper, but that it was a mineral, and was for the cure of distemper in dogs. Witness suggested Ethiop's mineral, and he said he thought that was it. It was a preparation of mercury and sulphur, and witness was in the habit of selling it as a dog medicine. Witness gave him ¼ oz. of it for 3*d*., and wrote on the packet "Ethiop's mineral." He did not add the word "poison," because it was not required for that article. The next evening the postman brought it back and said it was the wrong powder, and he had a ticket with him with the name of "Turpeth mineral" upon it. Accordingly he gave him 3*d*. worth of that article from a bottle he had bought with the stock of a chemist called Weeks, in this town, several years ago, and which was labelled "Turpeth mineral for dogs." He gave him ¼ oz. of that mineral, and labelled it, as had been seen, "Turpeth mineral—Poison." He had used it the last six years, and had never had it complained of—on the contrary, he had known of its beneficial effects as a medicine for dogs in distemper. Some time after the plaintiff called on him, and said he had come about the dog. Witness asked, "What dog?" He said, "The dog you killed. I want £2 for it." Plaintiff had stated in his evidence that he had not shown him the remainder of the powder; but that was not true—he had shown him what remained in the same paper which he (witness) had sent out, and had given him a portion of it, which he had compared with the contents of his bottle. It was turpeth mineral, and he had for the last six years sold it as such.

His Honour said it would be important to show whether the powder which was brought back by Rice was the same with that in the bottle in defendant's shop. After some conversation on the point, defendant was desired to go for his bottle of the article, and the Court in the meantime heard another case. On Mr. Hame's return after a short time he produced the bottle. (He had before produced to his Honour the portion of the powder he had received back from Rice, as well as a sample of red precipitate.)

The witness continued his evidence:—What he had supplied the postman he had taken out of that bottle. Ethiop's mineral was mercury and sulphur. He gave that article because he thought it safer for the purpose, for he did not like to sell poison to a customer when he did not know exactly what he wanted. The postman brought it back to him the next day, and he put it back into the bottle. He believed his bottle of turpeth mineral to be a somewhat impure sample of the article. It was turpeth mineral, but it was not thoroughly washed. It was precisely as he received it from the chemist whose stock he had bought off.

His Honour said the question was, as the customer had applied for turpeth mineral, was the article sold by the defendant a fair average compliance with the order?

Mr. Blyth was recalled, and said that turpeth mineral was basic sulphate of mercury. He could not agree with defendant that the contents of the bottle might be an impure sample of turpeth mineral, unless he tested it by analysis. The colour was different, but that, of course, determined nothing.

Mr. Hames said the colouring matter did not essentially vary the chemical properties of the article.

His Honour asked Mr. Blyth if he could analyse a sample of the contents of the bottle; to which he replied in the affirmative: he could get it done in an hour or an hour and a-half. A sample was therefore given to Mr. Blyth by the defendant, and he retired to make his analysis, the Court taking some other cases in the interval. After an hour or two Mr. Blyth returned, and the case was again resumed.

Mr. Blyth said he had analysed the sample given him by defendant from the bulk, and found it to be what was commonly called red precipitate, the technical name for the article being red oxide of mercury. It was exactly the same with the sample given him by the clergyman of West Buckland. It did not contain one particle of basic sulphate of mercury, which was turpeth mineral. It followed that turpeth mineral was wholly wanting from the article sold.

His Honour: Was the supplying of the article a substantial compliance with the order? or is it substantially a different article?

Witness: Absolutely different—different altogether. (Taking the label into his hands.) It should have been labelled "red precipitate." It is entirely another article.

His Honour was about to give judgment; when Mr. Bencraft said he should wish to call evidence as to the value of the dog, which had been greatly over-estimated by the plaintiff. He called Robert Cure, who said he had been a dog-fancier all his days, and that the value of the dog as a mongrel, judging from the description given of it, was 4*s*. or 5*s*.

His Honour, in giving judgment, said the article supplied by the defendant to the order of plaintiff was in no way whatever identical with the commodity asked for. If a person went into a chemist's shop, and requested to be served with a certain article, and it turned out that the article supplied to him was one of essentially different properties, the chemist must be held liable for the consequences of his mistake. At the same time he felt bound to state his full belief that Mr. Hames supplied the commodity precisely as he had bought it, and that he had been for years selling the article in good faith, supposing it to be what it had turned out not to be. As to the value of the dog, it had probably been as much over-estimated on one side as under-estimated on the other. His judgment was for 30*s*. for the value of the dog, and the costs, including those of witnesses.—His Honour begged the samples before him might be taken away, adding archly "that he had no wish to *take* them."—*North Devon Journal.*

Poisoning by a Vermin Killer.

An inquest was held at Bradford, on Friday, July 17, respecting the death of Ada Bolton, who died on the previous day from the effects of poison administered by herself.

Evidence was given that the deceased was seen to mix with some beer a white powder which she said was a "purging powder," and afterwards drink the mixture. One witness said that her conduct on the previous day had led her friends to think something had gone wrong with her; but that she had had four teeth drawn some two years ago, when "gas" was administered to her, and that since that time she had occasionally conducted herself strangely, and had said that the "laughing gas" had affected her head.

Dr. Ellis saw the deceased in bed. She was then suffering from violent tetanic spasms, which continued uninterruptedly for thirteen minutes, when she died. He asked her what she had taken, and the only words she uttered were "vermin killer." The symptoms were those of poisoning by strychnine. In answer to a juror, Mr. Ellis added that it was just possible for a highly nervous person to be slightly affected by nitrous oxide gas, administered in the process of tooth-drawing.

Phœbe Stephens stated that on the Bradford Fair Saturday, at the request of the deceased, she went with her to the shop of Mr. Parker, druggist, Leeds Road, and bought a sixpenny packet of vermin killer. *Neither of them was asked to sign a paper;* but the druggist told them it was poison. Deceased said she wanted it to kill rats with, and witness had no idea that she intended to do anything else with it.

After a long consultation the jury returned a verdict, "that deceased committed suicide by poison while in a state of temporary insanity."—*Bradford Daily Telegraph.*

Notes and Queries.

[406.] SOLUTION FOR BLOWING SOAP-BUBBLES.—*G. C. L.* asks for a formula for making a good solution for exhibiting the coloured rings, etc. The following will supply his want :—

Take of :

Marseilles Soap (cut in thin slices) .	1 part.
Distilled water	40 „

Dissolve with heat, and when cold, filter the solution.

Take of :

The above solution	3 parts.
Glycerine	2 „

Put them into a bottle and mix them by continued shaking, then leave it at rest. The mixture which at first is clear becomes turbid, and separates into two parts; the lower of which is clear, and this is to be separated for use. Bubbles blown with this solution will remain unbroken for hours or even for days.

Review.

ILLUSTRATIONS OF THE PRINCIPAL NATURAL ORDERS OF THE VEGETABLE KINGDOM; prepared for the Science and Art Department of the Council of Education. By Prof. OLIVER, F.R.S., etc. London: Chapman and Hall, 1874.

This work has long been expected, and will now be eagerly welcomed by science teachers and students. It has long been felt to be a desideratum in botanical literature that we have had no work the object of which should be to give in a short space, and in as few words as possible, the leading characters of each of the principal natural orders of plants. This plan has been admirably carried out in the volume before us, and the description of the greater number of the orders is further illustrated by a large plate, plain or coloured, representing the structure of the flower, fruit, seed, or other organ which presents distinguishing characters. A few lines are also given to the distribution and uses of the orders, the more important medicinal or economical plants belonging to it being named in each case, and, in the case of the larger orders, the characters of the tribes or suborders are also given. Special pains have been bestowed on those orders which often present such difficulty to the beginner, the Compositæ and Grasses. The work is intended for students of European and especially of British botany; the extra-European orders having no plates and much shorter descriptions devoted to them, and in the case even of some interesting orders, as Dipterocarpeæ, Gnetaceæ, Balanophoraceæ, etc., none at all. We might indeed well have spared the diagrams and plates of such orders as Droseraceæ, Frankeniaceæ, Halorageæ, Lemnaceæ, etc., to have made room for much more important ones, as Cycadeæ, Proteaceæ, Menispermaceæ, Melastomaceæ, Scitamineæ, etc. Defects of omission are, however, the only ones which it is possible to allege against the work. It is most valuable to the student, and absolutely indispensable to the teacher.

SCAMMONY.

Sir,—I see from the Pharmacopœia that after exhausting the scammony with ether the residue should be "chiefly soluble gum with a little moisture." Mr. Brown says Prof. Attfield's analyses (after exhausting the resin) "show 20 or 24 per cent. of extraneous matters, as chalk, starch, or flour, earth, moisture, etc." Will Mr. Brown be kind enough to inform me whether the gum in scammony is to be considered as an extraneous substance? or does he agree with Mr. Piesse that the gum is dissolved out by the spirit or ether used to extract the resin, so that the residue will contain only the above impurities?

Mr. Piesse increases the difficulty by saying that gum and gum-resin are the same things, and that after removing the resin from scammony there would be no gum in the residue; also about the residue, he says in one place, it would consist of "vegetable tissue and so on," and in another place he would expect to find about 20 per cent. of bark, scraped off with the exuded scammony, and his answer to the next question is that the 20 per cent. would not be bark, but *foreign substances*, not actual scammony resin.

I therefore gather from Messrs. Brown and Piesse that gum is a *foreign substance*, and not a *natural constituent* of scammony, but the Pharmacopœia leads me to suppose the contrary is the correct view.

My only object in thus troubling you is to get at the true state of the case.

W. G. GORDELIER.

Sittingbourne, July 16th, 1874.

Sir,—One cannot but admire the eclecticism of Mr. Brown's persistent maintenance of the 90 per cent. standard for scammony. It would be well if every chemist could satisfactorily reply to a humorous remark I once heard a customer make,—"I suppose all your goods are 'Opt.'" But in other matters than things pharmaceutical, the error is often made of confounding the ideal of excellence, the attainment of which should be every man's ambition, with the standard of judgment to which all men must submit. It is to be hoped that reaction will never go so far as to deprive an accused Englishman of his supposed right to the benefit of a doubt; on which principle he is palpably entitled to be judged by the lowest standard which can be called genuine. Prof. Attfield showed his common sense by quoting the lowest authoritative standard of the Pharmacopœia. It is one thing to purge our own store by the highest standard, but another thing to ask the policeman to take the same standard into our neighbour's.

I am neither an advocate for adulteration, nor an admirer of second qualities, but only a lover of justice, which, in the recent prosecution, did not need the tempering of mercy (so far as the evidence went) to acquit the accused.

HENRY H. POLLARD.

140, *High Street, Ryde, I. W., July 20th.*

THE IRISH PHARMACY QUESTION.

Sir,—In your Editorial Notes on the Irish Pharmacy Question, in the PHARMACEUTICAL JOURNAL of the 18th inst., you conclude a *résumé* of Mr. Mackay's evidence before the Select Committee on the Apothecaries' Licenses Bill, thus:—"If a body of pharmacists were provided for Ireland, he would advise the apothecaries to stick as closely as possible to medical practice, and leave the sale of drugs and dispensing of medicines to the class specially educated for that purpose."

While recognizing, with profound thankfulness, Mr. Mackay's no doubt well-meant advice, will you permit me, in the hope of removing some misapprehensions, to state briefly a few indisputable facts?

1. The licentiate apothecaries in Ireland are "the class who, hitherto, have been specially educated for the dispensing of medicines and the sale of drugs."

2. A very large number of Irish apothecaries confine their attention entirely to the practice of pharmacy; they are, in fact, pharmaceutical chemists.

3. Very few of them, indeed, practise medicine on the strength of the licence of the Apothecaries' Hall alone; those who do so, in nearly every instance, possess a qualification from some other medical or surgical licensing body.

I may be allowed to mention my own case as an extreme illustration. I possessed qualifications in medicine, surgery and midwifery; but preferring, for private reasons, to practice pharmacy only, I had to take the licence of the Apothecaries' Hall also to enable me, among other things, to obtain a public appointment as apothecary, and for the last seven years have avoided medical practice, though qualified to engage in it.

Referring to the subject of the Select Committee on Pharmacy, I wish to mention that two gentlemen representing the Licentiate Apothecaries in Ireland, one from Belfast, the other from Cork, presented themselves for examination before the Committee, but were informed that their evidence was not considered necessary.

I believe I express the feeling of those whom they represented when I characterize the refusal of their testimony as most unfair to the class whose prospects would be most materially affected by a change in the law respecting pharmacy in this country.

I enclose you two circulars, the contents of which, I trust, will explain the views the Irish apothecaries generally entertain.

REUBEN BOLTON, M.D., ETC.,
Hon. Sec. Association of Licentiate Apothecaries of Ireland.

Belfast, July 20th, 1874.

[*** We understand Mr. Mackay's remark as expressing his sense of the desirability of a thorough separation of the practice of medicine from that of pharmacy proper. We do not perceive in regard to this point what misapprehension there is to remove, and we look upon our correspondent's statement as to the course adopted by a very large number of Irish apothecaries as being quite in accordance with the view expressed by Mr. Mackay, in fact a practical endorsement of the propriety of that view. But however much we may approve the course taken by the Irish apothecaries in avoiding medical practice, we cannot overlook the fact that it is optional for them to do so or not, and we are disposed to think that in any legislation affecting the practice of pharmacy in Ireland that option should not be allowed to remain.—ED. PHARM. JOURN.]

THE PURITY OF DRUGS AND PHARMACEUTICAL PREPARATIONS.

Sir,—My attention has been drawn to an article in your journal of 27th June last, page 1033, in which reference is made to a parcel of quinine and cinchonidine offered in London.

As the 2000 ounces in question have been offered through my agency, you will allow me to lay the facts of the case before you, which I trust you will be kind enough to publish in your next edition.

You are doubtless aware that in the manufacture of quinine on a large scale different barks are used, containing, besides quinine, other alkaloids in various proportions. It so happened that the makers of the quinine in question obtained from certain parcels of bark a mixture of quinine and cinchonidine, which it proved to be rather troublesome to rectify; the question arose naturally whether this produce might not be used *tale quale*, in the manufacture of other quinine preparations, in the process of which the two alkaloids might be more easily separated. It was with this view alone that I offered the parcel in this market, in proof of which I may mention that I did not submit the offer to a single drug house in London. It is not correct that I represented the article as containing only a trifling admixture of cinchonidine. Not knowing the exact proportions of the two alkaloids, I could only advise to have it tested and examined.

I beg to enclose my card, and trusting you will publish the above explanations.

FREDERICK THOMAE.

9, *Gracechurch Street, July 18th,* 1874.

[*** The fact that Mr. Thomae identifies himself with the parcel of mixed sulphates of cinchonidine and quinine, referred to at p. 1033, entitles him to the publication of the foregoing explanatory letter although no names were mentioned in this Journal. At the same time we think it is only justice to Mr. Thomae to state that it was not his house that was referred to as having offered the parcel for sale under the representation that it contained a very trifling percentage of cinchonidine.—ED. PHARM. JOURN.]

EXCESSIVE LABOUR IN PHARMACY.

Sir,—I have read with interest the letters that have been written respecting the excessive labour in pharmacy. They put the case of pharmacists in a very fair light; much stronger things might be said, but sufficient has already been mentioned to show there is scarcely a parallel where a class of men required by law to be well educated, impose on themselves solitary confinement. It seems to me we look after everybody's health but our own.

I deny there is any necessity for such long hours. The gentleman ("Seven o'Clock") in last week's Journal hoped it would not end in verbage. It is our own fault if it does. I would suggest immediate action. Let some one who takes a real interest in the trade, and in the welfare of those engaged in it, especially those who have to meet the Examinations, canvass the town or neighbourhood in which he lives, and ascertain what the majority wish to be done. I shall be happy to do my part.

Perhaps a petition could be presented to Sir John Lubbock to support his bill. I feel sure it would be signed by almost every employer who has to attend to his own business, and every employee desires it. I speak thus confidently of success, beaause I have not seen a word written in defence of the present state of things, nor can there be, I think.

If any gentleman thinks the present hours, etc., are satisfactory, I would ask him to send me as a favour a reply to these questions, as often put to chemists by parents before they apprentice their boys. What are the prospects in your trade? What are the drawbacks?

RICHARD CARDELL.

Bodmin, July 21st, 1874.

Sir,—This subject appears to have the attention of a few well-meaning chemists.

"Seven o'Clock" says that there must be a change for the better, or he would prefer the position of a mechanic to that of a pharmaceutical chemist.

"Country Major Associate," comes to the conclusion that the appropriate name for chemist is Pharmaceutical Slave, and gives the minimum term of labour as twelve hours a day. It delights me to hear him say that the scarcity of assistants will compel him to close his business at a reasonable hour, viz., seven o'clock. Now, if there are 500 such assistants in the country as the one who has caused "Country Major Associate" to think of closing earlier, they may also secure for themselves better treatment at the hands of their employers, shorter hours and higher wages; then, as a natural consequence, chemists' prices would go up. Chemists appear to be sorely perplexed to find some means of raising their prices. Assistants can teach them one way, an orthodox one too, by demanding adequate salaries, and thus compel them to advance prices. When mechanics demand and obtain higher wages, do their employers suffer loss? Can it be true that chemists' assistants are too poor to support a trades-union? They are poorly paid as a class, but, if they wait till employers spontaneously raise their wages they will wait a long time.

Don't compare them to mechanics. A joiner can earn 8*d.* an hour, which in a lucky twelve-hours-a-day chemist's week, excluding the holy Sabbath, amounts to 48*s.*, taking no account of the item overtime. That is at the rate of £125 per annum. Where is the class of chemists' assistants commanding an equivalent salary.

In the City of Edinburgh three years ago, out-door assistants wages were something very like one-third of that sum, £40, or at the most £50, being the rule and not the exception.

I know of one instance where, on £40 a year an increase of £5 was promised after six months' service, but only on condition that in the interval "he shall have passed the Minor examination of the Pharmaceutical Society of Great Britain." There must be some cause for all this low remuneration and excessive labour.

I have an idea that there are even now too many chemists and far too many chemists' assistants in the country. If anyone can produce statistics to show that the number of masters and assistants has been either increasing or decreasing since 1868, he will afford valuable information. Assistants may then calculate the distance of the "good time coming," which they sometimes talk of. If the number of assistants is decreasing at the rate my observation leads me to believe, better times are at hand.

To secure shorter hours, "Seven o'Clock," recommends individual action on the part of assistants. Let there be such action, combined with united effort, and nothing can prevent the removal of such true grievances as low remuneration and excessive labour in Pharmacy.

ANTI-SQUASH.

18*th July*, 1874.

Sir,—Having read with much interest the communications to the Journal on this topic, I venture to add my trifling stimulus, and to offer a few remarks, with the hope that the subject now broached may be duly ventilated, and saved from the too frequent process of "shelving."

With respect to the sentiments of your "seven o'clock" correspondent relative to the immediate necessity of reducing the hours of toiling behind chemists' counters, they are undoubtedly worthy of consideration, but his suggestion that all assistants in the country should refuse a situation where the hours are longer than from 8 a.m. to 7 p.m., would be, if adopted, tantamount to a "strike," and that, I fancy, is extremely distasteful to the majority of those who are striving to keep a respectable position in the public mind. Besides, we must not forget that employers, for the most part, would be glad to accept any reasonable means for curtailing their own as well as their assistants' hours of drudgery, if some definite scheme were proposed; but, unfortunately, little progress is made at present, either that way or in the direction of better remuneration, owing to the want of a system of organization.

Now, Sir, I wish respectfully to suggest for consideration the desirability of a Society being established, with London for its centre, and branches in all towns throughout the kingdom, having for its object the regulation of prices, hours, and all matters connected with trade improvement; and admitting to membership every individual on the Register, whether employer or assistants, on payment of a very nominal annual subscription. By this means greater facility would be offered for the interchange of opinion, and much usefulness achieved in the way of suppressing those petty jealousies, which have hitherto frustrated any attempt at combination.

Trusting abler hands will come to the front,

"FESTINA LENTE."

The old adage "all work and no play, etc.," needs but very little alteration to make it applicable to "Pharmaceutical Slaves" as "Seven o'Clock" most justly termed chemists' assistants. If we said all work and no pay, I think it would be very nearly the truth, and express the true state of the generality of assistants at the present time.

I think the best mode of helping ourselves out of the difficulty would be to form some kind of an association, then we could have a stronger voice by unity. Why should we not combine and form a sort of society where we could discuss this kind of matter? A committee might be formed and then they could fix a salary for the Juniors, Minors and Majors, so that the subscribers to the affair would not take less salary than that arranged by the committee. I feel sure that we can raise our position without striking as has been suggested. If the several grades of assistants would not take less than that arranged, the employers would of necessity be compelled to give the required salary, and not offer to a Junior, as they do (who has perhaps paid 100 guineas for his apprenticeship), a paltry £15 or £20 per annum. Then, perhaps, after we get one thing, we shall be able to do something for early closing. I hope to see some suggestions in the Journal from those that are interested in the matter.

JUSTITIA.

Battersea, 21*st July*, 1874.

Sir,—Up to a tolerably recent period your Correspondence pages have been replete with letters touching on the question of higher remuneration for chemists' assistants. We are glad to see that lately the masters have brought forward their claims before the public. If we look at principals and assistants in their relative position with an impartial eye, it is not unlikely that it will be for the most part admitted that the chemist has more cause to complain than his assistant. The latter has, in the first place, the option of entering a service or not. The master cannot shift his locality without entailing great risk to himself. The assistant, as long as he is in the service of his superior, is always entitled to his full salary as agreed upon, no matter how dull business may happen to be, or how small the profits of the season. A few weeks ago there appeared in the PHARMACEUTICAL JOURNAL a letter from a master, who told how he was, perforce, as it were, bound to the counter for nearly the whole day through want of an effectual assistant, and how, while he could not find time for a walk for weeks together, his assistant had entered into an agreement, on first coming into his service, for three hours recreation per diem, and having no alternative, he could not but comply with this arrangement. Then looking at the responsibility of both parties, in nine cases out of ten, if the assistant makes a mistake, perhaps depriving someone of life, all the blame falls upon the master, who loses his reputation and business while the assistant may retrieve his character in some distant neighbourhood. At any rate the latter would not have the stigma of disgrace wherever he went. "Allowances," people say, "must be made for men in that position of life." Must, then, no allowance be made for a harassed and weary master, worn out by care and anxiety, striving to maintain a respectable appearance in the midst of troubles known perhaps only to himself? In conclusion, of course there is right and wrong on both sides, but it seems hard that the argument should be such a one-sided one as it is generally put forth.

VIR PRO BONO PUBLICO.

G. N. Robins.—The erasure would probably be a difficult operation; at any rate it would trench too much upon the surgeon's domain to admit of advice from us.

"*Hyoscyamus.*"—(1) We find upon inquiry that the statement made to you is quite correct. (2) Yes, it will be increased in stringency. (3) *Aconitum Napellus* is not unlike *A. ferox*; but the latter has a slightly downy appearance, and it is not a plant that would be likely to be shown to a candidate.

C. Johnson.—Clearly Tinct. Cinnam. Co. of the last London Pharmacopœia. It would not be justifiable to use the preparation of catechu mentioned.

J. W. (who should have enclosed his name).—We are unable to supply you with the information you ask for.

D.—The knowledge of materia medica required for the modified examination is essentially practical, and consists in the recognition of specimens and the estimation of their quality and freedom from adulteration.

W. G. Parkyn.—See the correspondence relating to Army Dispensers in vol. iv., p. 79.

W. F. C.—We do not know that it would be illegal, but it would be decidedly improper.

NOTICE.—Considerable inconvenience and disappointment is frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly in the advertising pages by the Publishers as to letters respecting advertisements or the sale of Journals, and over our Editorial columns, as to communications for the Editor, or for the Secretary, in reference to the transmission of Journals to members, etc., will prevent delay, and the consequent annoyance.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Welborn, Mr. Curtis, Messrs. Blackwood, Mr. Warwick, Mr. Goss, Professor Fluckiger, S. B., W. F. C.

CHEMICAL INVESTIGATION OF THE AIR IN ROOMS COVERED WITH ARSENICAL WALL PAPERS.

BY N. P. HAMBERG, M.D., OF STOCKHOLM,

Hon. Mem. of the Pharmaceutical Society of Great Britain.

The injurious effects of arsenical pigments as applied to the walls of apartments have been observed by physicians in almost every civilized country. The poisoning which occasionally results has been explained in very different ways. Several illustrious scientific men, as Taylor, Bunsen, and Pettenkofer, consider that it is due to fine particles, removed by mechanical causes from the paper, which, mixed with the air of the apartment, enter into the respiratory and digestive organs, and thus set up poisonous symptoms; consequently that danger could arise only from paperhangings to which arsenical colours were but loosely attached, and that the air is not contaminated by such colours, when varnished or applied as oil paints.

On the other hand, we have many observations of poisoning occurring in rooms, where the arsenical paper was covered with other paper completely innocuous, or where the walls were painted with an arsenical pigment ground in oil. It is therefore probable that a gaseous arsenical compound, arsenide of hydrogen, or oxide of kakodyl, escapes from the colour; and the experiments performed by Professor H. Tleck in Dresden (*Zeitschrift für Biologie*, Bd. viii.) induced me to make further investigations, which I think may interest the readers of the PHARMACEUTICAL JOURNAL. I therefore communicate the results of an examination which I commenced during last summer and have lately completed.

The experiments were performed in a summer residence, which was let to me and my family during the summer of 1873.

The room taken for the experiment was a large one, with two windows opening to the west; its walls were dry, and the papering of the room had according to report been put up 25 to 30 years before. No smell of damp was perceptible; and the persons who let the rooms said that they had not observed, either in themselves or others, any injury to health which could be ascribed to the green papering.

The apparatus used by me is represented below and consisted of the following parts:—

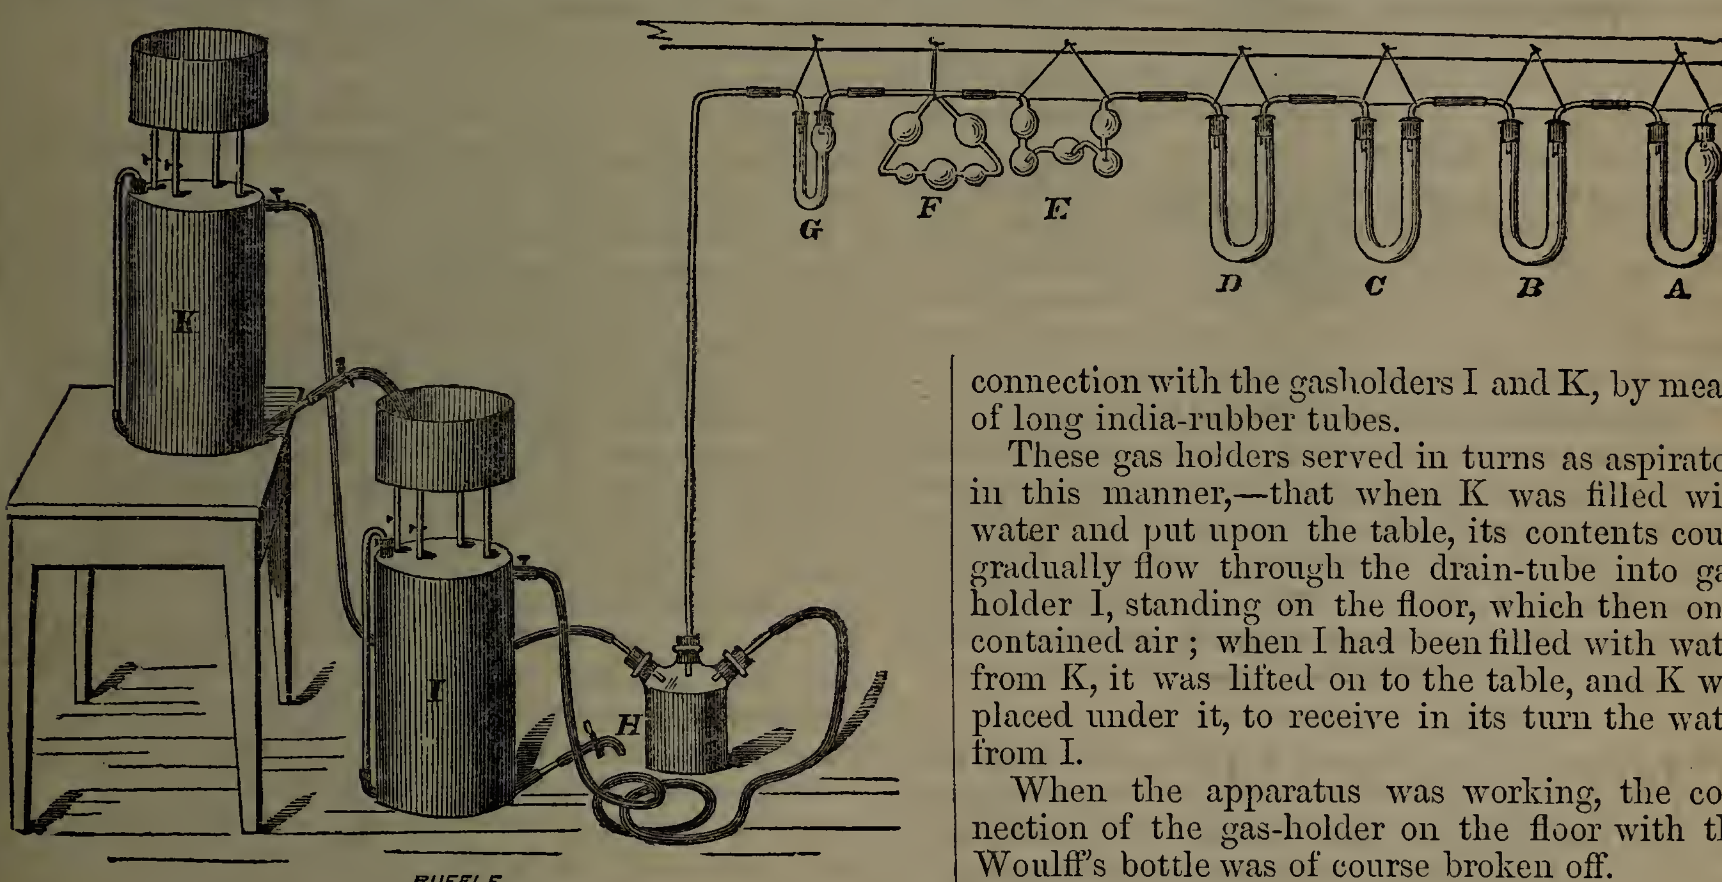
The U-formed tube A, containing only air, the object of which was to gather any possible dust.

The tubes B, C, D, contained cotton, by which the air was filtered, and quite freed from dust, previous to entering *the bulb-shaped tubes E and F*, which contained a solution of nitrate of silver (1 part to 40 parts of water).

The tube G contained only air, and was used in order to receive any solution of silver that might be splashed over by the stream of air from the bulb tubes.

The above-described system of tubes was hung on the wall opposite the windows.

The tube G was united by a long glass tube to the three-necked Woulff's bottle H, that was placed on the floor, and the lateral necks of which were put in connection with the gasholders I and K, by means of long india-rubber tubes.



These gas holders served in turns as aspirators in this manner,—that when K was filled with water and put upon the table, its contents could gradually flow through the drain-tube into gas-holder I, standing on the floor, which then only contained air; when I had been filled with water from K, it was lifted on to the table, and K was placed under it, to receive in its turn the water from I.

When the apparatus was working, the connection of the gas-holder on the floor with the Woulff's bottle was of course broken off.

The gas-holders I and K had each a capacity of 15 litres; the lower opening of each was provided with a perforated cork, into which a bent glass tube with a short india-rubber pipe was inserted, which by a screw stop-cock could be shut and opened. On opening this stop-cock, there ran out from the gas-holder that was filled with 15 litres only about 10 or 11 litres, and a stream of air corresponding with this quantity of water thus passed through the set of tubes.

During the experiment, the doors and windows were shut as much as possible, to make the change of air in the room more difficult.

The passage of air through the set of tubes was continued daily from the 16th of July to the 16th of August, when it was stopped. In one to two hours, 10-11 litres of water had flowed from the gas-holder, and a corresponding quantity of air had been passed at the same time through the set of tubes. Every removal of the gas-holders was noted, and on an average the removal was made 8 to 10 times a day.

At the interruption of the operation on the 16th of August, water had been emptied from the gas-holder 216 times in the above-mentioned manner. If the quantity of water is supposed to be 10 litres every time, 2,160 litres, 2,160,000 cubic centimetres of air had passed during the experiment through the set of tubes. While the experiment lasted, I many times felt on entering the room, after having been in the fresh sea-air, a disagreeable alliaceous smell, certainly not strong, but yet evident.

When the passage of air through the set of tubes had continued about one week, a black sediment in the solution of silver in the tube E was observed; the sediment increased by degrees, and appeared afterwards also in the bulb-tube F.

On the 16th of August the passing of air was discontinued, and the apparatus taken down. The contents of the separate tubes, A to G, were examined after removing to town, and at this investigation the following observations were made :—

Contents in the U-shaped Tube A.

The object of this tube was, as I have said, to gather dust. On examining it scarcely any solid particles could be observed. In the room taken for the experiment, which was a drawing-room, and not generally used by the family, there was but little dust; the papering was, as is before mentioned, *old*, and the colour very well fastened.

To detect the presence of any arsenical colour, the tube was washed out several times with dilute nitric acid, the acid fluid was allowed to evaporate, and a little of it was examined with yellow ferrocyanide of potassium, but no reaction on copper was obtained, and only a little iron could be observed.

The remaining part of the acid fluid was evaporated to dryness, and was heated with sulphuric acid to remove all nitric acid; the residue was poured into a Berzelius-Marsh apparatus, with a heated reduction tube; notwithstanding a continued passing of gas through the constantly glowing tube for an hour and a-half, only an excessively feeble, indistinct pellucid film was obtained.

Cotton from the Tube B.

The cotton taken out was heated with nitric acid, the tube being washed out; the acid was evaporated, and the residue mixed with nitrate and carbonate of sodium, and heated in a porcelain crucible to fusion, which was continued till all organic matter was destroyed. The fused mass was dissolved in water, when a little ferric oxide was left, the solution was super-saturated with sulphuric acid, and afterwards heated to remove all nitric acid.

The acid residue gave in Berzelius-Marsh's apparatus a feeble arsenical film, which began to appear not very plainly after passing the gas for ten minutes through the glowing reduction tube, but became evident after one hour's continued passage of gas and heating.

Cotton from the Tubes C and D.

The contents of these tubes were separately examined in the same manner as the contents of tube B, but neither from C nor D could any arsenical reaction be obtained.

Solution of Silver in the Bulb-tube E.

The black sediment formed during the passage of the air was separated by filtration. A small portion of the filtered liquor was saturated with ammonia, which produced a light-yellow sediment resembling arsenite of silver. The greater part of the filtered liquor was mixed with hydrochloric acid, in order to precipitate the silver, the chloride of which was collected on a filter, and the clear fluid evaporated to dryness; the remainder was treated with sulphuric acid, and heat applied so long as nitrous vapours were exhaled. After dilution with water, the acid liquid was poured into a Berzelius-Marsh apparatus, provided with the usual reduction-tube; after ten or twelve minutes, a feeble brown tint was observed, and after one hour's passing of the gas a pellucid brown film was obtained that, in the contracted part of the reduction-tube, collected into an apparent arsenical crust of such a thickness that it was not transparent.

The black sediment in the solution of silver was easily dissolved by diluted nitric acid, and displayed the characters of metallic silver; on further examination it appeared to contain a little sulphuret of silver.

Solution of Silver in the Bulb-tube F.

The solution in this part of the apparatus had changed in the same manner as in E, though in less degrees; the quantity of the precipitate was smaller, and it yielded a correspondingly smaller amount of arsenical crust.

The tube G contained a little solution of silver that had been carried with the stream of air from the bulb-formed tube F.

I consider that the above-mentioned investigations and observations prove that, from the papering in the room in which the experiment was conducted, a gaseous arsenical evaporation was going on; the change that happened in the solution of silver agrees with that which would be produced by arsenide of hydrogen, namely, a sediment of silver and a formation of dissolved arsenite of silver, and makes it probable that the gaseous compound which was formed was arsenite of hydrogen, which gas also can be produced at an ordinary temperature. Oxide of kakodyl, on the contrary, arises first by heating to redness, and forms, with nitrate of silver, a crystallized compound, and thus causes quite another effect on nitrate of silver than these experiments proved.

Some observations concerning the papering in the room are now to be mentioned. The papering had, as it was said, been put up twenty-five to thirty years ago, and the walls in the room were very dry. The papering had a beautiful, light-green ground, with an ornamental pattern of brownish-yellow.

The brownish-yellow colour was ferruginous—probably some ochre. The green colour resembled Schweinfurt green, and proved to contain a considerable amount of arsenic. A square centimetre of the paper gave, after solution and testing in a Berzelius-Marsh apparatus, with a tube of reduction of seven millimetres opening, an arsenical crust more than six centimetres long, and so thick that the greater part of it was opaque. The above-mentioned green colour proved, upon examination, to contain but a small amount of acetic acid, yet a considerable amount of carbonic acid. When dissolved in ammonia, and mixed with a solution of magnesia containing chloride of ammonium, a precipitate was formed after some minutes, which was found to be arseniate of magnesia and ammonia. The colour of the papering appears thus to have gradually undergone an alteration in composition; one part of arsenious acid has been oxidized to arsenic acid, while another part has been reduced, and has combined with hydrogen. A great part of the acetic acid has been changed to carbonic acid.

Finally, it ought to be mentioned that none of the family experienced any remarkable injury to health while residing in the house, but that I, who had my bedroom beside the room in which the experiments were made, and often during the night had the door open, felt in the morning a heaviness in the head and weariness. How far an attack of rheumatism in the legs, from which I suffered during the month of July, and which still lasted during the first months of 1874, can be ascribed to the green paper of the room, is questionable.

NOTE ON PROCTER'S REACTION OF GALLIC ACID.

BY PROFESSOR FLÜCKIGER.

In this Journal, July 18th, 1874, p. 43, it is stated that a mixture of faintly alkaline arseniate and gallic acid in aqueous solution by absorption of oxygen developes a green colour.

There can be no doubt as to the correctness of the fact. I wish only to point out that the arseniate, that is to say, arsenic acid, has nothing whatever to do with this reaction. The phosphates, borates, silicates, carbonates, etc., may quite as well be used instead of the arseniate. The cause of the green reaction is the presence of a trifling amount of alkali, a fact which has long been well known and expressly recorded, for instance, in Gmelin's 'Organic Chemistry,' among other reactions of gallic acid. The reaction is developed by any alkali, caustic or not, provided it be present in but extremely small quantity. Thus bicarbonate of sodium is a very convenient means of showing the reaction under notice; it displays, it need scarcely be mentioned, but a very moderate alkaline action.

The green reaction, it will be observed, has its merit, as it is not produced either by gallotannic acid or by pyrogallol.

There is another reaction which likewise is sufficient to distinguish gallic acid. If to an aqueous solution of gallic acid some drops of a dilute solution of ferrous sulphate (about one part of vitriol in 100 of water) are added, the mixture remains for some time colourless, provided the gallic acid be free from tannic acid, and the ferrous salt from ferric; the solutions, moreover, ought to be made in the very moment they are to be used. Ferrous gallate is of an intense violet hue; but it is not produced in the above mixture, because the solution of the sulphate has an acid reaction. This is due to sulphuric acid, which can be superseded by acetic acid if we add a little acetate of sodium. Then a trace of acetic acid is set free, and this now is not able to prevent the development of the violet colour of ferrous gallate; an intense violet instantly makes its appearance.

THE MICROSCOPE IN PHARMACY.*

BY HENRY POCKLINGTON.

(Continued from Vol. IV., p. 549).

WOODS.—The examination, microscopically, of woods for diagnostic purposes is not quite the same thing as the examination of stems.

When we deal with stems we have, as I said when speaking of roots, to discuss, seriatim, the relative development of the medullary, wood, and cortical layers and the several tissues composing them, as well as note the morphology of these tissues themselves. But there are many cases where we have to depend entirely upon our knowledge of the minute structure of one of these tissues, for our determination of its origin. This is the case with barks and woods as found in our materia medica, and our difficulties reach their culmination when we have to deal with these woods in the form of a more or less fine powder.

To enable us to deal with these we must very thoroughly familiarize ourselves with (*a*) the nature of wood structure generally, and (*b*) the minute structural anatomy of the woods of the materia medica, and of, at least, those likely to be substituted for them or mixed with them.

We may roughly class the tissues of which wood is composed in three groups: (*a*) vascular, (*b*) prosenchymatous, (*c*) parenchymatous. The two latter may be subdivided into parenchymatous-prosenchyma and into woody-parenchyma, of which the latter is very common and very variable. These three classes and their subdivisions may co-exist in the same wood, or one or more may be absent. Their presence or absence, their relative proportions, and their distribution and character are the points which will aid our diagnosis of any particular wood.

A few words about each of these tissues may perhaps be useful.

The *Vascular* tissues comprise spiral vessels (in the medullary sheath only) and pitted vessels of very various kinds. These latter may have a spiral ternary deposit, as in Elm and Daphne, with or without bordered pits as in Lime, and very characteristically in Tamus, Sassafras and certain Cycads. Sometimes the bordered pits when present are on two or three sides only of the duct, as in Elder, Beech, and Apple. The absence of a vascular system will at once direct the attention of the observer to Conifers. Speaking generally, the character of the vessels and their markings, the size of the pits, their shape and inclination, afford great help in determinating the nature of any wood.

The *Prosenchymatous* tissues proper are characterized by their spindle-shaped cells; where this character is much departed from, the tissue should be called prosenchymatous-parenchyma. The wood-cells may be minutely pitted or, as in Conifers, glandular. In the latter case, attention should be paid to the nature of the so-called glandular marking, whether it is crossed singly, as in Salisburia, or doubly without a spiral, as in Abies, and with a single spiral, as in Taxus, or double spiral, as in Auracaria.

The *Parenchymatous* tissues pretty sharply distinguish themselves by their globular, cubical, or rhombohedral shape and their thin walls. They may be porous, as in Elder, very distinctly pitted, as in the medulla of Cinchona, or have a spiral deposit, as in Orchidaceæ. When the cell-walls are much thickened or the cells are much elongated, and approach in these particulars the nature of wood-cells, with which they may be associated, these tissues should be called prosenchymatous-parenchyma. The co-existence of woody parenchyma with true wood-cells is of great diagnostic value. A good example of this co-existence may be seen in the wood of the Elm, very differently in the Apple, and very slightly in the Beech. In one or two trees the direction of the wood-fibres with regard to the vertical axis of the tree is of importance to be noted. This is the case in Lignum vitæ, where the wood-cells

* I have again to apologize to my readers for delay in the completion of this series of articles. As a large portion of the delay has been due to ill-health, no further apology is, I trust, needful. The whole remainder of the series, with one unimportant exception, is now in MS., and no further delay will occur.

interlace very intimately, producing an unusually tough wood that will not readily split or cleave in any particular direction. The relative thickness of the whole of these tissues is to be noted; but too much stress should not be laid upon it, as this feature is exceedingly variable, and is to a great extent determined by the age of the tree. Still the relative thickness of the tissues is much more constant, specifically, than might be expected.

A few words on the course pursued in the examination, and I pass on. The *nature* of the tissues, *i.e.*, the groups to which they belong, are best studied in longitudinal section.

The wood-cells and one feature of the medullary rays, their outline in cross section, and the markings on the porous vessels, are seen most advantageously in longitudinal sections crossing the rays. The woody parenchymatous cells, with their frequently crystalline contents, on the other hand, are best seen in sections running parallel, as far as may be, with the rays; that is, in radial sections. The relative distribution of the tissue and the character of the wood generally must be studied in cross sections, which must be exceedingly thin. It is desirable to mount all these sections in either glycerine, or glycerine jelly, but one section of each should be carefully stained with magenta and mounted in balsam or dammar. Use may in a few cases, guaiacum for example, be made of a strong solution of caustic potash, in which the section should be boiled to remove colouring matters and clear the tissues. In other cases, where the wood is highly charged with colouring matters, soluble in alcohol or ether, the section should be treated with these agents until the colour is extracted. It is hardly necessary to say that, in the case of such woods, examination should always be made of them in their normal condition in order that the seat of the colouring matter may be ascertained and the vessels or cells containing it carefully noted. It should in these cases be ascertained, if possible, whether the cells containing the colour are associated with the vessels, and whether they are more or less highly specialized, or whether the vessels themselves are the seat of the colouring matter. In the latter case, it should then be made a subject of inquiry whether the colouring matter was produced in them, or, more probably, elaborated elsewhere and located there, and whether *post-mortem* or not. Out of these will arise a further query, which I cannot discuss here at present, whether, in the case of compound colouring matters, these exist in the plant in their compound state or separated and in their own special cells. When this is found to be the case, separate observation should be made, by optical and chemical means, of the several substances in their native cells.* I pass now to the woods of the Pharmacopœia.

(*To be continued.*)

IS OZONE A CONCOMITANT OF THE OXIDATION OF ESSENTIAL OILS?†

BY CHARLES T. KINGZETT, F.C.S.

It is generally stated in books that the oxidation of oil of turpentine is attended with the production of ozone. Thus, in vol. iii. of 'Miller's Chemistry' it is stated, "Oil of turpentine gradually absorbs oxygen from the air, with the formation of a certain proportion of ozone;" and in Gmelin's work (vol. xiv.) it is written, "Oil of turpentine absorbs oxygen gas, acquiring new properties, and being converted into ozonized oil of turpentine."

Further, Lawes, Gilbert, and Pugh have stated their belief that the supposed ozone existing in the vicinity of vegetation is due to the oxidation of hydrocarbons evolved by plants (*Chem. Soc. J.* [2], i., 1863, p. 100).

These statements, variously modified, have been so often repeated, that at last they are almost universally received as matters of facts. But although a vast amount of work has been done on this subject, especially by Schönbein, whose peculiar views on the matter are so well known, yet it cannot be said that the information is absolute. On the other hand, there has ever existed more or less doubt about the formation of ozone by the oxidation of such bodies as oil of turpentine.

It was with the view of acquiring more certain knowledge that the author made a series of experiments, the results of which are recorded in a paper recently read before the Chemical Society.

In commencing his experiments he first of all wished to get some definite notion as to the rate of absorption of oxygen by such bodies as oil of turpentine. For this purpose the liquid to be experimented upon was enclosed in a graduated tube containing air or oxygen, and the volume of the gas read from time to time. It was thus seen that ether, potassium-naphtha, oil of turpentine, and such bodies rapidly absorb oxygen from air or oxygen gas.

A few cubic centimetres of naphtha absorbed 25 c.c. of oxygen in 36 days, *i.e.*, the whole of the oxygen present. In yet another experiment with air, the turpentine oil (not in sunlight) absorbed 10·5 c.c. of gas during 14 days, that being the theoretical amount of oxygen in the air used.

Benzene showed no absorption of oxygen during 40 days. After this, similar experiments were made with the oils of bergamotte, chamomile, caraway, cloves, juniper, lemon, thyme, capivi, cubebs, etc., etc.

The numbers given in the following table are not valuable as showing the absolute relative absorption of oxygen by the various substances, as some were conducted in sunshine whilst others were not.

Body used.	c.c. Oxygen absorbed.	No. of days.	= daily.
			c.c.
Oil of caraway......	18 (from oxygen)	6	3
„ bergamotte ..	12 „	4	3
„ juniper	5 „	2	2·5
„ cubebs	4 „	2	2
„ lemon.........	16 „	13	1·2
„ Naphtha	25 „	33	·7
Oil of turpentine... in sunshine (*a*)	220 „	6	36·6
„ turpentine... in shade (*b*)	20 „	36	·6
„ turpentine.. in shade (*c*)	10 (from air)	14	·75
„ chamomile...	6 (from oxygen)	11	·55
Ether (absolute) (*a*)	6·5 „	34	·19
Ether (absolute) (*b*)	6·5 (from air)	34	·19

These bodies, which had thus absorbed known amounts of oxygen, were agitated after the experiment with a mixed solution of potassium iodide and starch, when they invariably developed the well-known blue colouration more or less quickly. It is remarkable that this colouration does not take place immediately, as one might suppose would be the case if these bodies contained dissolved ozone.

On the other hand, in the case of the bergamotte above given, where 12 c.c. of oxygen had been absorbed, there was absolutely no colouration with the potassium iodide

* There is here a fruitful and, I believe, an untilled field for observers with leisure.

† Abstract of a paper read before the Chemical ociety (*Journ. Chem. Soc.* [2] vol. xii., p. 511).

and starch for some minutes, but it then gradually became of an opaque blue. The same remark applies to the other cases for the most part.

Evidently, therefore, an agent now existed in these oxidized oils, having properties like those possessed by ozone.

This fact was confirmed by taking the various bodies and placing them in tubes, together with a solution of potassium iodide, covering the mouths of the tubes with paper, and exposing to diffused daylight. Ether, naphtha, and turpentine and caraway oils gave almost immediately a yellow line between the two layers, showing either that they precontained the active agent, or quickly produced it. Time was required in all the other cases, in all of which affirmative results were obtained and rendered very evident by the addition of a solution of starch. Confirmation of these results was further obtained by placing the substances in tubes heated to 70° C. by means of a steam-bath, and spreading over the mouth of the tubes paper soaked in the potassic iodide starch mixture. But the best results were obtained by mixing in watch-glasses the substance to be tried and the test-solution.

As the oils of turpentine and caraway were found to give the most decided reactions, most of the subsequent experiments were confined to them. These experiments, which are recorded at length in the original paper, led the author to the conclusion that the active agent produced in the oxidation of these oils, although possessing properties similar in many respects to ozone, is not ozone or peroxide of hydrogen, but an oxidized principle derived from terpene ($C_{10}H_{16}$), namely, a monohydrated oxide of turpentine ($C_{10}H_{16}O{\cdot}H_2O$). The evidence upon which this conclusion is based is thus summarized :—

When oil of turpentine is exposed to air or oxygen, in presence of moisture, it oxidizes, producing an agent which resembles ozone and peroxide of hydrogen, inasmuch as it gives a similar reaction with potassium iodide. It further resembles peroxide of hydrogen, because it gives a violet colouration with chromic acid solution acidulated with sulphuric acid. It cannot, however, be peroxide of hydrogen, because, although it is somewhat soluble in water, the solution retains its properties after long-continued boiling. It again resembles the aforementioned bodies by being totally destroyed by peroxide of manganese, but it also differs from them by having much more stable properties, resisting, to a certain extent, the action of sodium hyposulphite, and temperatures considerably above the boiling-point of water. Although destroyed by peroxide of manganese and other agents, the body again forms on exposure to air and moisture.

Lastly, the active agent so like to ozone is destroyed at the boiling-point of oil of turpentine, viz., 160°, and temperatures at which ozone and peroxide of hydrogen are not destroyed, when chloride of zinc is present. It is also destroyed by other dehydrating agents and by certain deoxidizing agents.

It is increased in amount by heating to 100° in presence of water, but in the oil which distils over at that temperature, there is none of it. Simple exposure to air is, however, alone necessary for its formation, and then it has the same properties as the parent oil.

Oil of turpentine is generally credited with the power of ozonizing the air in its vicinity, as well as with the power of dissolving a certain amount of the ozone to which its oxidation is supposed to give rise. This is because it has long been known that potassic iodide test-paper exposed to its vapour speedily indicates the well-known reaction of ozone ; but this must now be explained by the oil evaporating and oxidizing to this peculiar product, for the oil which has been subjected to the action of peroxide of manganese or chloride of zinc, or any of the other means which have been pointed out as efficient in destroying the active principle, no longer has the power of so influencing the air in its vicinity, until it has been allowed to stand in contact with air (and moisture ?) for some time.

By experiments now in hand, the author hopes to be able to adduce more conclusive evidence as to the composition and constitution of the oxidized product of oil of turpentine, which possesses such interesting properties ; also to show more precisely the circumstances under which it is produced, and to build it up synthetically from terpene or cymene, etc. For the present he can only hint at its nature. His notion, as has already been stated, is, that it is $C_{10}H_{16}O.H_2O$.

1. By the loss of H_2O_2 this becomes $C_{10}H_{16}$. Sulphuric acid causes, by its action upon the oxidized oil, the formation of a body which gives a violet colouration to chromic acid solution.

2. By the loss of $2H_2O$, the body becomes $C_{10}H_{14}$. Chloride of zinc destroys the active agent, and $C_{10}H_{14}$ (cymene) is a product of its action upon $C_{10}H_{16}O$.

3. By the loss of O it becomes $C_{10}H_{16}.H_2O$. Deoxidizing bodies, as pyrogallate of potash, etc., also destroy the active agent. These data combine to show that the constitution of the body is as represented. It is also a fact that $C_{10}H_{16}O.H_2O$ is somewhat soluble in water.

THE PROBLEMS AND FUTURE OF PHARMACY IN GERMANY.*

BY FRED. HOFFMANN, PH.D.

(*Concluded from p.* 70.)

It is not the aim of this essay to parallel the conditions and prospects of American pharmacy with those just described, nor to determine whether and how soon the same questions may come up here, or whether the present state of American pharmacy really justifies the exalted views of the future, as occasionally expressed in valedictories and similar addresses. In its trade relation it has practically the advantage over German pharmacy, inasmuch as it still stands upon the basis of a commercial trade, and cannot therefore be injured in a similar manner by being displaced from a professional basis, secured by a noble career of usefulness and achievements through more than two centuries.

As a natural consequence of the growth and extent of sciences, and the increase and diffusion of learning and a more correct knowledge of nature, which is the tendency of modern times, we must view the fact that an enhanced general, as well as special, education is becoming more necessary in all pursuits. and gives the impulse to innovations and reforms, particularly in those pursuits which are based upon the knowledge of the laws of nature, and upon the application of the principles of physical and sanitary sciences, and that this agitation is felt in medicine and pharmacy, precisely as in other circles.

After the first abortive legislative attempt in several States of the Union in demanding directly, and without previous preparation, a higher qualification, the education of pharmacists, and in consequence thereof a superior status of pharmacy, has made successful progress, and increased facilities for attaining this aim have been inaugurated by the establishment of, and increased attendance at, the various pharmaceutical schools.* In this advance movement, pharmacy stands, however, by no

* If no other, at least one result of high value must be acknowledged to be due to the continued agitation for, and the enactment of, laws regulating the practice of pharmacy, namely, the increased attendance of the pharmaceutical pupils at the courses of the colleges of pharmacy. Although this attendance is not yet dependent upon a preliminary examination and qualification, and though the want of sufficient primary education and knowledge is *à priori* prejudicial to the full value of a course of theoretical study compressed into so short a time, capable and assiduous young men will find at least the path pointed out, and receive the incitement for the further acquisition of knowledge, while American pharmacy will, for the next generation, be supplied with new productive heads and hands for its scientific continuance.

means alone; generalization and unity of sciences on the one hand, and education, scientific knowledge and higher intellectual culture, on the other, are, as already stated, the demands of our time, and this tendency pervades, in our country, all classes of its population and all pursuits, and is practically exemplified in the increase and prosperity of all higher educational institutions,—the medical, polytechnic, commercial and other colleges,—and in the entire literature of the present day.

Pharmacy in the United States will therefore probably meet with fewer difficulties on its high road to improvement, and the less so, as it is in the happy position of profiting by the pharmaceutical experience and acquisitions of older countries, and particularly of Germany, without having to undergo the struggles and errors of its gradual development extending over two centuries. The problems which it will inevitably have to encounter with the progress of time and civilization I have briefly referred to above, and they are more fully stated in Mr. Danckwortt's and Prof. Hlasiwetz's papers; aside from other more technical and less important arguments, they have been felt here likewise for some time, and have been repeatedly and timely expressed,* but appear not to have received due consideration.

The lively interest taken by the American people in progress and the questions of the times, its acceptation for new ideas and their practical application, leave no doubt that the modern popularized teachings of hygiene and of the sanitary and medical sciences which are promulgated by the advanced schools of medicine and by popular literature,† as well as of medical scepticism, will here find a fruitful soil, just as homœopathy has found its adherents not merely among the ign rant, but rather among the wealthier and educated classes of society. The consequences of such a popularization of a more correct knowledge of hygiene and of rational methods of preventing disease, and preserving and restoring health without the former resort to unwise and excessive medication, must be the same here as in Europe, as far as the material emoluments of the pharmaceutical pursuit are concerned, and inasmuch as they will in time greatly diminish the income of the pharmacist, they will also be in direct antagonism with the demands of modern times for higher education, which requires increased expenditure of time, labour, and money. All legislative restrictions and regulations will prove one-sided and without real and permanent value, as long as they aim to raise the claims for a higher qualification and standard only, without affording, on the other hand, some guarantee for a sure and remunerative application of the higher proficiency, and for the conditions necessary for the material prosperity of the practice of pharmacy. Compared to the physician and the tradesman, the pharmacist occupies an exceptional position; the former applies his individual knowledge and skill without investment of capital or risk, and without any restriction; the merchant chooses his wares according to demand and want, and can control his investments quantitatively and qualitatively; he employs labourers or clerks with less knowledge and without responsibility; his wares usually retain their value, and are less prone to deterioration. In this material age and concrete and practical country of ours, there cannot be expected, for any length of time, an acquisition of talent and skill, or a permanent and steady elevation of a calling whose resources appear to be everywhere on the decline,* and which involves an amount of time, resignation, and responsibility as no other pursuit requiring a similar amount of learning, and which, for superior attainments and proficiency, does not offer an adequate equivalent in the shape of pecuniary compensation.

These are some of the problems which American pharmacy will likewise have to encounter sooner or later, and in the discussions of which the recourse to the whole truth will unquestionably prove the best remedy for the evils of imperfectly stated truth. They certainly deserve earnest consideration, and invite our congenial interest in the pending struggle of pharmacy in Germany for its existence and continuance. Whatever may be the future fate of pharmacy, that of Continental Europe has the high merit of having fulfilled its mission of culture, and particularly in developing and applying the natural sciences, and mainly chemistry, and that its achievements are not perishable, but on the contrary will for ever be useful in the further evolution of the healing art and of applied chemistry in general.

THE INSECT ENEMIES OF DRUGS: THE BEST MEANS OF PROTECTING SOUND DRUGS FROM THEIR RAVAGES, AND OF DESTROYING THEM WHEN ALREADY IN DRUGS.†

BY W. SAUNDERS, LONDON, ONTARIO, CANADA.

The insects which take up their abodes in, and consume the various substances kept in a drug store, are more numerous than one might at first suppose, some few of them occurring in abundance almost every year, while others are less frequent or rare; hence the opportunities for investigating their habits are not always alike favourable. It would be a difficult task, were one possessed of much more leisure than has fallen to my lot, to undertake to exhaust this apparently small field of research in a single season. I will, however, state what I have been able to gather relating to two of our more common foes, and report, if permitted, on the rarer ones on future occasions, as opportunities may present themselves.

In years past my own drug stock has suffered far more from destructive insects than it has during the current year. What to attribute this relative scarcity to, I know not; there are so many influences operating from time to time favourably or otherwise on insect life—some of which elude our observation entirely—that one is often quite at a loss to give a reason why an insect should be present in the greatest abundance one year and comparatively rare the next, the circumstances in each case being apparently similar. In any case this scarcity is not to be deplored, not even with an accepted query on the subject in hand, for the destructive powers of some of the species are truly formidable, where their numbers are sufficiently great.

First, because with me most injurious, I would place what has been called by Dr. Fitch, State Entomologist of New York, "The Indian-meal moth," *Tinea zeæ*, so named because it was first found in Indian-meal, although by no means exclusively partial to it. The varied character of the appetite possessed by this creature during the larval

* The practice of our profession is becoming more arduous, —its scientific relations more complicated, as civilization and science advance, while its legitimate rewards diminish, because the scope of the business contracts, while competition increases, and it is evident that, unless we can arrest or overcome these, we cannot long retain in our ranks a superior or desirable *personnel*. The char cter of any pursuit depends upon the men who fill it, and we cannot have men of culture and attainments unless they are adequately rewarded. (D. C. Robbins, annual address, N. Y. Alumni Assoc., 1872-73.)

† *Proceed. Am. Pharm. Assoc.*

or caterpillar stage of its existence, is something wonderful, very few substances seeming to be distasteful to it. It thrives equally well on aconite root and taraxacum, devours both with avidity, large roots being frequently so completely riddled by the numerous channels made through them that one can crush them between the finger and thumb. In the case of aconite, it would be interesting to know whether the active and poisonous principle of the root is actually appropriated to the nourishment and sustenance of these worms as well as the starchy matter, or whether they possess the power of eliminating from their food noxious or injurious elements, and thus reject the alkaloid in the frass. This point I have not been able to determine. Rhubarb, either in root or powder, is esteemed a dainty morsel by this omnivorous creature, and is eaten as readily as pearl barley or burdock; ergot is also a favourite article of diet, and I have reared it on currie powder, and have even found it feeding on Cayenne pepper. Surely, with such an accommodating appetite, this insect could scarcely ever die for want of suitable food.

When the material fed on is in large pieces, such as roots, this larva forms cylindrical or sometimes somewhat tortuous burrows or excavations through it, which are lined with a silky web, more or less of which protrudes about the orifices, where it is sometimes mixed with rejected fragments of the material and the excrement of the worm. Where the substance is in smaller pieces, such as ergot or pearl barley, or, in case of a crushed root, the larva fastens together with silken threads a sufficient number of particles or pieces to enable it to provide for itself within a secure place of retreat.

When full grown this caterpillar measures about half-an-inch in length, and is nearly cylindrical in form. Its head is of a yellowish-brown colour, with a polished horny appearance, and on the second segment, immediately behind the head, is a yellowish, horny-looking plate, which covers most of the upper part of the segment, and with a surface resembling that of the head, but of a paler hue. There is also a spot on the last segment of a similar character. The colour of the body is dull whitish, with a few minute tubercles or smooth raised dots scattered over its surface, from each of which there arises a fine pale hair, scarcely visible without a magnifier. When disturbed it moves forward, or wriggles itself out backward with almost equal facility.

When fully mature, the larva changes to a chrysalis within the chamber already excavated, where it reposes in a slight silky cocoon, attached to the side of the silk-lined chamber. The cocoon is made of very white silken fibres, and through this slight covering the pupa may be readily seen. The latter is about one-third of an inch long, of a pale dull yellowish colour, ringed with darker brown lines, the large black eyes of the future moth showing through this partially transparent inclosure.

After remaining in this inactive condition for a sufficient length of time, varying with the period of the year and the temperature of the atmosphere, the winged moth bursts its bonds and prepares itself for flight. When fresh from the chrysalis, in common with other moths, its wings are but partially developed, are not more than one-fourth of their normal size, and quite incapable of sustaining in flight the weight of the body to which they are attached, but shortly, as soon as the newly escaped insect can place itself in a favourable position, where the wings can hang downwards, a marvellous process of growth begins, when in a few moments the wings acquire their full dimensions. When we consider that this growth implies, not a mere extension of the membranous structure of the wing only, but the maturity and expansion of every scale upon the wing, the individuals of which appear but as the finest dust to the unaided eye, we may well wonder at the intricate system of circulation and nutrition by which such a marvellous change is so rapidly brought about.

When its wings are expanded this moth measures from one-half to six-tenths of an inch across, and may be readily recognized by its having the basal third of the wings dull white or cream-coloured, while the outer portion is of a dark grey or blackish shade; they have also a somewhat greasy-looking surface, and the scales which cover the wings are easily rubbed off when the moth is handled. There is usually a dull yellowish spot, more or less defined, a little beyond the middle of the wing, and sometimes the hind margin is slightly banded with the same colour. The hind wings are nearly white, with a glossy surface, and margined with a long silky fringe. The body is dark-grey, with sometimes a little yellow behind the head. Beneath, the fore wings are paler than above, with a satin-like lustre, and the hind wings are whitish.

There are some substances which this insect seems to avoid; the following I have never known to be injured, although freely exposed where the insect was abundant: podophyllum, leptandra, menispermum canadense, gentian, gelseminum, hydrangea, geranium maculatum, sanguinaria, senega, and sarsaparilla. The cinchona barks also seem free. Cimicifuga, in the unground state, has escaped injury, but when crushed, or coarsely ground, it is soon taken possession of by this foe.

The meal moth, *Pyralis farinalis:* the larva of this insect very much resembles that last described, but the moth it produces is very different. The common name meal moth has been given to it on account of the injury it does to various farinaceous substances. *Tinea zeæ*, the insect last referred to, is, we believe, a native of this country, but *Pyralis farinalis* is an imported insect, brought over from Europe, where its destructive habits have long been known. I have found this insect very partial to the flaxseed in its unground state. While quite young the larva fastens together a number of the seeds into an irregular mass by means of glutinous silky threads, constructing in the centre a hollow chamber in which it lives, the diameter of which is enlarged as the larva grows. It does not confine itself to flaxseed, but attacks other substances as well, especially those of a farinaceous character, although it is not nearly so general a feeder as *zeæ*.

The caterpillar is of a dull whitish colour, with the head, a plate on the upper part of the second segment, and a spot on the terminal segment pale reddish-brown, with a polished, horny-looking surface. This worm may also frequently be found in old flour barrels. Its history in the chrysalis state is very similar to that of the insect last described.

The perfect moth may frequently be seen on the walls and ceilings of rooms sitting with the hinder segments of its body curved over its back. When its wings are spread it measures about an inch across. The fore wings are light brown, with a large, dark, reddish-brown spot at the base, and another smaller one near the tip of the wing. Two wavy, whitish lines extend across the wings, the inner one bordering the dark patch at the base. The hind wings are paler, with wavy, whitish lines, and clouded with spots and streaks of pale brown. The under side is much paler than the upper.

With regard to remedies, prevention is better than cure; hence by providing proper vessels in which to store the various substances the pharmacist keeps in stock with suitably fitting covers, much damage of this sort may be prevented; but where the insects have already gained foothold, I know of no better method of destroying them than one suggested by Dr. Squibb, which is by the vapour of chloroform. A ready way of applying this is to pour a little of the liquid on a small piece of sponge, and place it in a shallow tin box or other suitable vessel, and close the lid of the package containing the infected drug tightly, so as to prevent free access of air. The vapour of the chloroform, in consequence of its density, falls on the material, and diffuses itself through the entire mass, carrying death wherever it goes. Where the moths are found to be abundant, they may be attracted and poisoned while in the winged state by exposing cloths wet with a mixture of molasses and strong solution of arsenic, to which a few drops of essence of pear have been added.

TINCTURE OF IODINE.*

BY P. CARLES.

It is well known that after being kept a certain time tincture of iodine is modified in its properties, and becomes unsuitable for certain uses, such as for injection in cases of hydrocele, tumours, etc. Guibourt was the first to call attention† to the decomposition which this tincture undergoes, and in 1846 he brought it under the notice of the French Academy of Medicine. He rendered this decomposition palpable by mixing with two equal quantities of water an equal weight of each of two tinctures, of which one was recently prepared and the other was some months old. From the first all the iodine was precipitated, the supernatant liquid being scarcely coloured yellow; whilst the second, in consequence of the greater quantity of iodine which remained in solution, preserved a more intense colour. Guibourt attributed this facility of solution to the intervention of hydriodic acid which had been formed at the expense of the alcohol.

In 1850, M. Gopel presented a memoir upon the same question, and attempted especially to determine in what proportion the iodine diminished in the mixture, or in what proportion hydriodic acid was formed. For this purpose tincture of iodine was treated with reduced copper, which removed the free iodine, without touching that which was in combination, in such a manner that it became easy to estimate the latter under the usual form of iodide of silver. This mode of separation, however, could not be considered as very exact, for the cuprous iodide was slightly soluble and was ultimately estimated as hydriodic acid, thus affecting the exactitude of M. Gopel's results. His conclusions, nevertheless, were, that in the course of time hydriodic acid and hydriodic ether are formed in tincture of iodine.

Finally, in 1859, M. Commaille re-examined the same question and arrived at the conclusion that the alteration in tincture of iodine, far from being rapid, is very limited, and may almost be prevented by the employment of black bottles. M. Commaille the free iodine from that which was in combination by the aid of portions of starch paste, which he successively mixed with tincture until there was no further blue colouration; the hydriodic acid in the residuary liquor was then estimated as iodide of silver. This method of separating the iodine also appears to be inexact, for the large proportion of starch would take up also a portion of the hydriodic acid. Moreover the figures given by these two authors present such a wide divergence that M. Carles has thought it desirable to publish the results of fresh experiments conducted in a different manner.

The following was the method of operating adopted:—The tincture of iodine was diluted with eight times its volume of water, and the mixture filtered in order to remove the greater part of the precipitated iodine. The clear filtrate was agitated with an excess of carbonate of baryta and again filtered. The baryta which had entered into solution in the state of iodide of barium was then estimated as sulphate, which allowed of a calculation being made of the quantity of hydriodic acid, formed at the expense of a given weight of the alcoholic tincture of iodine. In this way the author found that a tincture, after being prepared ten months (from August to May), and exposed in a white flask to diffused light, contained 1·12 part of hydriodic acid (HI) to 100 parts of tincture. M. Gopel had asserted that a portion of this acid exists in the tincture under the form of ether, but M. Carles, like his predecessor, has not been able to isolate it.

The question therefore arose, whether a normal tincture, to which the proportion of acid found had been added, would be susceptible of producing the bad results which are attributed to old and decomposed tincture. Practically, this has not been found to be the case, and M. Carles thinks the defect should rather be attributed to other products of which the nature is not at present known, but which h eproposes to further investigate.

BARYTA, ITS MANIFOLD USES IN THE ARTS.*

BY DR. LEWIS FEUCHTWANGER.

The various salts of baryta have long been employed in pyrotechny; as admixture to white lead; as material almost indispensable to card-makers for a permanent white; in sugar refining; in chemical operations, etc.

In nature we find but few varieties. The sulphate, composed of 66 per cent. baryta and 34 per cent. sulphuric acid, is abundant in England, France, Germany, and the United States, where it most generally is found in connection with beds or veins of metallic ores, as gangue, or veinstone. Sometimes, however, it forms distinct veins, in company with secondary limestone, and very often in fine crystals, along with calcite and celestite. Crystals of large dimensions occur in Westmoreland, Cornwall, Cumberland and Derbyshire, in England. Beautiful specimens of septaria, cut and polished for table and other ornaments, having linings of brown heavy spar, are wrought in Durham, England, in Hungary, at Freiburg in Saxony, Clausthal in the Hartz, in Bohemia, and in Auvergne, France.

The localities in the United States are very numerous. The States of Connecticut and Missouri have long furnished abundant material for the arts. Next come Virginia, New York, New Hampshire, Massachusetts, Pennsylvan ia, Kentucky, and Tennessee. In Canada fine crystals occur, and massive baryta in a 27-foot vein. It is reported from New Mexico also.

The Bologna spar is the ornamental stone, of a brown colour and concentric rings, originally found in a bed of clay near Bologna, where it formerly was considered a great curiosity, on account of its phosphorescence, displayed after heating with charcoal, and it was called the Bologna phosphorus. The common name of sulphate of baryta is heavy spar or barytes; specific gravity 4·5, and hardness 3. It is found in nature in large crystals, weighing 100 lbs. and more, and in slender needle crystals; also in massive aggregations of tabular crystals likewise columnar and radiated, and in globular and nodular concretions; also lamellar and granular, earthy and stalactitic.

The sulphate of baryta often occurs associated with lime and some silica and alum, and is then called calcareobarite; and if it be associated with strontia, it is called baryto-celestine. If the sulphate of baryta gives out a fetid odour on striking or rubbing it, it is called fetid baryta. The name of baryta is derived from the Greek word, βαρὺς, heavy.

Witherite is a carbonate of baryta, having a specific gravity of 4, and a hardness of 3·2, and consists of 78 per cent. of baryta and 22 per cent. of carbonic acid. This is found in considerable quantities in England, at Alston Moor in Northumberland, in Silesia, Hungary, Styria, Sicily, Chili, but not much in the United States. It is extensively employed in manufacture of plate glass and the manufacture of beet-root sugar in France, and for the production of *blanc-fixe*, or permanent white; it is much used of late for paint, particularly in combination with soluble glass and white oxide of zinc.

The metallic base of the baryta salts is called barium, and is obtained from the carbonate of baryta or chloride, of barium, if put in a platinum dish and connected with the positive pole of a strong galvanic battery, in order to decompose it, mercury being placed in a hollow made in the baryta and connected with the negative pole. The result is an amalgam, which may be distilled in a bent tube filled with hydrogen. Barium is a white, malleable and fusible metal, which oxidizes easily in the air and decomposes water at common temperatures. For the purposes of obtaining the pure baryta or barium oxide, the nitrate is calcined at a red heat in a silver or porcelain crucible, or the carbonate is mixed with pulverized

* A paper read before the Polytechnic Club of the American Institute. Reprinted from the *Journal of the Society of Arts* of July 24, 1874.

charcoal in a covered crucible, and exposed for an hour to a strong heat. If oxygen gas is passed over it, it will absorb that gas with avidity and become a peroxide. This is the substance used at the present day for production of the peroxide of hydrogen, which is much recommended as a medical reagent, and employed in the arts for bleaching animal tissue, or converting brown into blonde hair. To prepare it, the peroxide of barium is treated with hydrochloric acid, and the liquid, previously decomposed with sulphate of silver, is carefully evaporated to a syrupy consistency, when it yields a slight chlorous odour. It decomposes easily into water and oxygen, and it is therefore almost impossible to prepare it properly in hot weather. At 212° F. it decomposes with violence.

The oxide of barium, or caustic baryta, unquestionably rivals in its causticity, potash, soda and ammonia, and may be easily employed in the compounds with chromic acid.

The chloride of barium is obtained by fusing the sulphate of baryta, or native heavy spar, with chloride of calcium (the residue from the preparation of ammonia) in a reverberatory furnace, and subsequently extracting with hot water, leaving the sulphate of lime undissolved.

The chlorate of baryta, which is now extensively used for producing a green flame in the manufacture of fireworks, is prepared by dissolving artificial carbonate of baryta in chloric acid solution, when it forms beautiful shining tabular crystals. It is dangerous to keep on hand when mixed with charcoal or sulphur.

Nitrate of baryta, which is likewise used in fireworks, may be easily prepared by dissolving the native carbonate in nitric acid and evaporating the solution, whereby octahedral crystals of the nitrate are deposited.

The native sulphate of baryta is generally used for the adulteration of white lead or paint, to the extent of 25 to 50 per cent. Of this mineral 4,000 tons are produced annually in Connecticut, and 2,000 tons in Missouri, while 10,000 tons are imported in England and Germany. The native mineral, if very white and free from iron coating, is finely ground and floated with water. But most of the native mineral contains fine particles of iron, and hence requires a different treatment, namely, calcination for some hours, in order to oxidize the iron to a higher degree, when hot water and, if necessary, a little sulphuric acid, will take up all the iron, and a beautiful white heavy powder is deposited, which is then dried, either by steam or in the same manner as whiting is dried, in the atmosphere. White oxide of zinc, as well as white lead, may be mixed with sulphate of baryta in linseed oil as a pigment, which is then fit for in and out-door painting, and spreads well.

The artificial sulphate, called white or *blanc-fixe*, which is now largely manufactured in France, England, and the United States, is used in the manufacture of a paper of the purest white, in imitation of linen, utilized for cheap collars, skirts, and cards. It was formerly manufactured from the native carbonate of baryta, but is now prepared from chloride of barium, which is obtained in England as a waste product at a reduced price. This is decomposed with sulphate of ammonia, and pure sulphate of baryta is precipitated. Another process for obtaining the chloride of barium, in order to prepare the permanent white, is by the decomposition of the native sulphate of baryta with chloride of sodium in a strong fire, and the subsequent solution of the fused mass in boiling water. The result is chloride of barium and sulphate of soda or glauber salt. About 5,000 tons of permanent white are annually manufactured in the United States and Europe.

In the chemical laboratory, the barium salts are indispensable for the determination of sulphuric acid, which forms the sulphate as an insoluble precipitate. The carbonate of baryta is a strong poison to animals, and is used for killing rats, etc.

A green paint, composed of manganese and caustic baryta, under the name of manganese green, has been brought to market from abroad, but was soon superseded by the beautiful Guignet green, a composition of aniline and iodine.

The beet sugar-refiners of France have very successfully employed both caustic baryta and the carbonate in their operations. They treat, first, the saccharine juice with lime, and then with carbonic acid, in order to clarify it. Afterwards they add baryta in order to obtain an insoluble precipitate, a saccharate of baryta. After passing sufficient carbonic acid gas under pressure of about half an atmosphere upon this precipitate, a separation takes place, and, without any evaporation, the hot solution is left to crystallize.

In copper metallurgical operations the sulphide of barium has latterly been employed for the purpose of precipitating from an ammoniacal copper solution the copper as a sulphide, which is treated in the usual method for reduction, either by caustic lime or by borax, or by a galvanic current.

The artificial carbonate of baryta, obtained by passing carbonic acid gas through a sulphide of barium, whereby the carbonate of baryta is precipitated, is much used in Europe in glass making for producing an achromatic glass. In 1826, I assisted in Jena my teacher, Koebner, in experiments for this object.

ELIXIR OF PHOSPHORUS.

The following formula for an "elixir of phosphorus" is supplied to the *American Journal of Pharmacy* by Mr. G. J. Luhn, of Charleston, S. Carolina, who states that it has been satisfactorily prescribed by a number of physicians in that city:—

℞	Phosphorus	gr. i.
	Æther sulph. conc.	f℥iiss.
	Alcohol	f℥i.
	Tr. menth. pip.	f℥ss.
	Glycerin. . . q. s. to make	f℥iii.

The phosphorus completely dissolves in the ether in about twenty-four hours, care being taken to introduce no water into the ether with the phosphorus. After the solution of the phosphorus is effected, the alcohol may be added, but the glycerin should be added in small portions, and the mixture shaken after each addition, and allowed to stand until it becomes clear before another portion of the glycerin is introduced.

A great deal of care has to be exercised in the addition of the glycerin; if too much be added at a time it will disengage a quantity of phosphorus, which will fall to the bottom. The essence of peppermint may either be added with the alcohol, or as the last ingredient; the latter is preferable, especially if the preparation is not made with 95 per cent. alcohol.

This preparation contains one-twenty-fourth grain of phosphorus to each fluidrachm, or teaspoonful. It is quite burning to the taste, but can easily be administered in a little simple syrup, when it will not be at all unpleasant to take. It has quite a milky appearance when mixed with syrup, but the author does not think the phosphorus is precipitated, at least not rapidly enough to prevent its being taken.

Mr. Luhn has also often added fluid extract of nux vomica to this preparation in quantities of three drops to each fluidrachm, and in this form it has been styled compound elixir of phosphorus.

SOLUTION OF CITRATE OF MAGNESIUM.*

BY J. C. WHARTON.

In preparing solution of citrate of magnesium, a quick process is sometimes desirable, especially if the customer is to drink it at the store, and happens to be "*in a hurry.*" The formula, as it now stands in the last edition of the United States Pharmacopœia, is not adapted to such a case, and it is to be regretted that the proper authorities did not construct it so as to admit the substitution of

* From the *Tennessee Pharmacal Gazette*, July, 1874.

calcined magnesia for carbonate of magnesium, in the proportion of 80 parts of the former for every 182 parts of the latter, or what is sufficiently near that proportion, 4 parts for every 9 parts or $\frac{4}{9}$ as much calcined as is directed of the carbonate. This would make 88 grains of calcined magnesia, sufficient to replace the 200 grains of carbonate of magnesium directed in the new Pharmacopœia. The advantage derived from the use of calcined magnesia is that a considerable amount of heat is evolved, which aids in making a rapid solution.

Another gain may be made by keeping prepared a syrup of bicarbonate of potassium, containing 20 grains of the salt to a fluidounce of simple syrup, flavoured with two minims of spirit of lemon. Two fluidounces of this syrup are to be used instead of the syrup of citric acid, while the citric acid, which should be contained in that amount of syrup, is to be added to the remainder of the acid in making the solution. This will render unnecessary the syrup of citric acid, but will otherwise make no difference in the preparation, except to facilitate the generation of the carbonic acid gas after the bottle has been securely stopped and well shaken.

To be brief, the following outline of the process is presented, with formulas modified, so as to be substantially the same as authorized by the United States Pharmacopœia :—

First.—Omit syrup of citric acid.

Second.—Prepare syrup of bicarbonate of potassium, as follows :—

Take of—

Simple syrup	2 pints.
Spirit of lemon . . .	64 minims.
Bicarbonate of potassium	640 grs.

Mix and make solution, keep ready for use.

Solution of citrate of magnesium.

Take of—

Calcined magnesia	88 grs.
Citric acid	408 grs.
Syrup of bicarbonate of potassium .	2 fluidounces.
Distilled water, *a sufficient quantity.*	

Mix the magnesia and citric acid in a mortar, and add one and a half fluidounces of water, stir with a pestle, and break up the lumps of acid, if any. After solution is effected, add sufficient water to make up the amount of one bottle nearly full when mixed with the syrup, strain if necessary. In bottling, *pour the syrup in first,* avoiding contact with the mouth and sides of the bottle as much as possible. Then pour upon it the solution as gently as possible at the start, afterwards more rapidly, letting the liquid run down the inside of the bottle so as to avoid agitating the syrup. Then cork and tie down the stopper, and shake the mixture. It will be ready to use immediately.

There will be an excess of acid, but it will make the preparation more palatable. It is probable, however, that 400 grains would be all-sufficient. The syrup should be thick. If a little care be taken, there will be scarcely any escape of carbonic acid gas from the bottle, as the liquid will dissolve it almost as fast as generated. In fact, there will be less than is usually lost when the bicarbonate of potassium is employed in small crystals or in powder. It is possible, however, to use finely powdered bicarbonate of potassium to a good purpose, if a simple, flavoured syrup, *minus* the citric acid, be also used. In this case, put the bicarbonate in the bottle first, then the syrup, and lastly, the solution of citrate of magnesium, cork tightly, as usual, and shake. This will be ready almost as soon as shaken, but the syrup of bicarbonate of potassium renders the process more expeditious, as the weighing out of the bicarbonate is dispensed with, by being included in a measured portion of syrup.

These recommendations are not intended to imply any superiority as to the quality of the solution thus prepared over that made by the present authorized formula, but it is medicinally the same, and may be made in a shorter time.

PRESERVATION OF CATERPILLARS BY INFLATION.

Mr. Samuel Scudder describes, in the *American Naturalist* for June, an admirable method for the preservation of caterpillars, first introduced by Mr. Gossens, of Paris, by which the delicate colours, as well as the hairy or spiny appendages, are better preserved than by any other method. The instruments necessary for the operation, of which drawings are given in the original paper, are a small tin oven, a spirit lamp, a pair of finely-pointed scissors, a pair of forceps, a little fine wire, and a straw, a fine glass tube being sometimes substituted for the last. The caterpillar is first killed by a drop of ether, or a plunge in spirits ; and, if hairy, should be allowed to remain at least half-an-hour in alcohol, and then to rest on bibulous paper for forty-eight hours, to prevent the hairs subsequently dropping off. The vent is then slightly enlarged by a pair of scissors, the caterpillar laid on bibulous paper or soft cotton cloth, and the contents of the body forced out through the enlarged vent by very gentle pressure between the finger and thumb, gradually advancing from the tail to the head ; the intestinal tube being removed by a pair of forceps. Great care must be taken not to injure the skin, or to allow any of the contents of the body to soil its exterior; if cleverly performed, the body is then reduced to a mere pellicle. A syringe is sometimes used for the extraction of the contents. A straw of the proper size is then selected, and the skin of the caterpillar carefully drawn over it without creasing it, for nearly a quarter of an inch, and fixed by passing a delicate pin through the anal plate and the straw. The oven is then heated, and the caterpillar kept extended horizontally on the straw by blowing gently and steadily through it ; and it may, from time to time, be withdrawn for a short time, to improve the shape with the fingers. It should be dried until a rather forcible touch will not cause it to bend ; it may then be removed and is ready for mounting. A piece of wire a little more than twice the length of the caterpillar is cut, bent double, and introduced into the empty skin as far as the forceps will allow ; the skin is then drawn very carefully over the wire, on which a little shellac has been placed, which will smear the inside of the skin and fix it when dry, the free extremities of the bent wire reaching nearly to the head. The doubled end of the wire is then bent lightly round a pin, and the specimen placed where it will dry thoroughly for two or three days before it is removed to the cabinet. This mode of preserving caterpillars is said to be in extensive use on the Continent of Europe.

FIRE AT A WHOLESALE DRUGGISTS'.

On Tuesday last the extensive block of premises belonging to Messrs. Wright, Sellers, and Layman, wholesale druggists, etc., situated in Southwark Street, Blackfriars Road, London, were destroyed by fire. The premises were secured by large iron shutters, and were six floors in height. At four o'clock A.M. a passing police-constable had his attention drawn to a cracking noise proceeding from Messrs. Wright's premises. Upon crossing the road he was met by a body of smoke issuing from the lower part of the building. The powerful steam fire-engine, by Messrs. Merryweather, stationed at Southwark Street, was the first to arrive on the spot, but the flames had now made terrible progress. Immediately after the firemen had begun their labour an explosion took place, blowing down the front of the building and the large iron shutters. Several members of the fire brigade had a narrow escape of being buried beneath the falling *debris.* This explosion was followed by a second one, which hurried the second and third floors, with two of Chubb's heavy iron safes, to the ground, causing great excitement among the vast number of spectators who had assembled to witness the conflagration. By half-past five the place presented a total wreck, and the flames were then threatening the buildings on either side, but the firemen happily succeeded in saving them.

The Pharmaceutical Journal.

SATURDAY, AUGUST 1, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

WITHIN the last few days we have learnt with some surprise that many members of the trade in the metropolitan district were still unaware what were to be the proceedings next week in connection with the Conference meeting. In order to supply the want of information in this respect, we think it desirable to repeat somewhat more fully the general sketch of the programme published in this Journal some weeks since.

In the first place, the business and pleasure work of the meeting will extend over four days, commencing on the 5th and ending on the 8th of August. During the first three days there will be an Exhibition of objects relating to Pharmacy, in the rooms of the Pharmaceutical Society's house at Bloomsbury Square. This Exhibition will be open on those days from ten in the morning until six in the evening, and, if we may judge from previous exhibitions of the kind, it will no doubt be both useful and interesting to many of our visitors.

On the evening of Wednesday next there will be a Conversazione, given by the President, Vice-President, and Council of the Pharmaceutical Society, to which all members of the Conference are invited.

On Thursday the special business of the Conference will commence, as usual, at ten o'clock, with the election of new members, the reading of the Report of the Executive Committee, and the reception of Delegates. Then will follow the Address of the President-Elect, Mr. T. B. GROVES, and after that the reading and discussion of papers will be proceeded with.

In the evening of Thursday, the Annual Dinner of the members of the Conference and their friends will be held either at the Inns of Court Hotel or elsewhere, as may be found desirable. Of this timely information will, of course, be furnished by the Local Secretary to those who have communicated their intention of being present.

On Friday, the reading and discussion of papers will be continued, and the election of officers will terminate the general business of the meeting.

On both these days Luncheon will be provided in the upper rooms of the Society's house, between 12.30 and 2 o'clock, the Local Committee inviting all who attend the meetings to partake of it. In this way, loss of time and trouble will be avoided.

For the purpose of showing at one glance not only the hours at which the above-mentioned engagements, but also those at which the meetings of the Executive Committee are to take place, we have drawn up in a tabular form, the following list, which we hope will prove useful as a remembrancer.

DAY.	HOUR.	BUSINESS.
WEDNESDAY . . .	10 A.M. to 6 P.M.	Exhibition of Objects relating to Pharmacy.
" . . .	4 P.M.	Meeting of Executive Committee.
" . . .	8 P.M.	Conversazione.
THURSDAY	10 A.M. to 4.30 P.M.	Meeting of Conference: Election of Members—Report—Reception of Delegates—President's Address—Reading of Papers and Discussions thereon.
"	10 A.M. to 6 P.M.	Exhibition.
"	12.30 to 2 P.M.	Luncheon, set out in the Upper Rooms.
"	7.30 P.M.	Annual Dinner of the Conference.
FRIDAY	9 A.M.	Meeting of Executive Committee.
"	10 A.M. to 4.30 P.M.	Meeting of Conference: Election of Members—Reception of Delegates—Reading of Papers and Discussions thereon—Election of Officers, etc.
"	10 A.M. to 6 P.M.	Exhibition.
"	12.30 to 2 P.M.	Luncheon, set out in the Upper Rooms.
SATURDAY	———	Excursion down the Valley of the Thames, between Marlow and Maidenhead.

On Saturday there will be an Excursion from London to Cliefden Wood and Maidenhead, to which provincial members of the Conference and foreign delegates are invited by the London members of the trade. A special train will convey the party by the Great Western Railway from Paddington to Great Marlow, where boats will be in readiness for continuing the journey by river through one of the most picturesque parts of the Thames valley, past Cookham Dean and Cookham to Cliefden, where, by the kind permission of the Duke of Westminster, the party can land, to ramble through the woods for a while, until it is time to return to the boats and proceed to Maidenhead Bridge, at which place luncheon will be provided. In the evening a special train will bring the party back to London.

Among the other arrangements that have been made for the convenience of visitors must be mentioned the provision of a room for their special accommodation, at the Inns of Court Hotel, in Holborn, and close to the Society's house. This hotel has been selected as the "head-quarters," where probably most of the provincial members of the Conference will stay, and thus have a greater opportunity of becoming acquainted with each other than if distributed in different parts of London.

Before concluding our account of the various features of attraction of this meeting, we must add the following list of papers to be read. It is perhaps subject to some revision, but will nevertheless show that there will be much interesting matter brought before the meeting.

Barnes, Mr. J. B.—Notes on Extracts.
Barton, Mr. H.—Liquid Extract of Sarsaparilla.
Flückiger, Professor.—The Stearopten of Oil of Nutmeg. A second Paper on another subject.
De Vrij, Dr. J. E.—Chemistry of Cinchona Bark, with reference to its use in Pharmacy. Extract of Pomegranate Root Bark as an Anthelmintic.
Gerrard, Mr. A. W.—The Official Plasters; improved formulæ for their preparation.
Groves, Mr. H.—Medicinal Plants in popular use amongst the Tuscans.
Groves, Mr. T. B., F.C.S.—Further Report on the Aconitine Bases.
Haffenden, Mr. H.—The Confections of Pharmacy.
Heathfield, W. E., F.R.S.E.—Notes on Extracts of Aconite, Belladonna, Hemlock, Henbane, and Colchicum.
Hunt, Arthur.—Notes on Chinese Pharmacy in Hongkong.
Keyworth, Mr. G. A.—The Decomposition of Water.
Muir, Mr. M. M. P., F.C.S.—Potable Water, and its contamination in House Cisterns.
Proctor, Mr. Barnard S.—The Diluted Hydrocyanic Acid of Pharmacy.
Savage, Mr. W. D.—Apprentices, Assistants, and Masters, and their relative duties.
Schacht, Mr. G. F., F.C.S.—Experiments on Juice and Extract of Conium.
Shenstone, Mr. W. A.—Notes on the Diluted Hydrocyanic Acid of Pharmacy.
Smith, Mr. E.—Utilization of Iodoform Residues.
Stoddart, Mr. W. W., F.C.S.—Modification of Liebig's Process for the estimation of Phosphoric Acid. Notes on Sulphate of Copper.
Tichborne, Professor.—The use of Oleic Acid in Pharmacy.
Williams, J.—The Preservation of Diluted Hydrocyanic Acid.
Wright, C. R. A., D.Sc.—On the Essential Oils of Wormwood, Citronella, and Cajeput. New Derivatives from the Opium Alkaloids.

THE REPORT ON THE APOTHECARIES' LICENCES BILL.

The Special Report of the Select Committee on the Apothecaries' Licences Bill, which we publish this week at page 94, will, at any rate, dispose of this matter for the present Session of Parliament. We think, however, that it will be found to bear internal evidence that the investigations of the Committee have failed to elucidate many essential points connected with the contemplated amendment of the law as regards the practice of pharmacy in Ireland. In many respects the recommendations of the Committee appear more like the expression of a foregone conclusion than the result of thorough consideration of all the facts of the case.

There is also an air—we had almost said a peculiarly Irish air—of inconsistency in the recommendations. Thus, for instance, while recognizing the importance of complete reciprocity between Great Britain and Ireland in regard to the practice of pharmacy, the Committee offers the recommendation that a distinct Pharmaceutical Society should be created and maintained for Ireland. To our mind such a proceeding would be totally incompatible with that reciprocity which the Committee declare to be admissible.

The reasons given for recommending the formation of a separate Pharmaceutical Society for Ireland do not bear out the conclusion. The fact that there has been for many years in Ireland a licensing centre for pharmacy is, we conceive, of less importance than the fact that, as regards pharmacy, that institution has become abortive. Indeed, the exclusive privileges enjoyed by the Apothecaries' Company, and the conditions it imposes in granting licences can only be justified on the ground that an apothecary should prescribe as well as dispense. We do not think it is saying too much to describe this as an antiquated view, and one inconsistent with present tendencies.

The argument that a local centre would be more conducive to the scientific and professional development of pharmacy in Ireland than extending the operation of the Pharmaceutical Society of Great Britain would be, seems utterly fallacious when it is remembered that the like extension of that Society to Scotland actually provided, in that case, not only the local centre, which is rightly considered to be necessary, but also a large portion of the funds requisite for maintaining it.

We do not perceive from what source funds in Ireland, adequate for such a purpose, are to be derived, and if the suggestion to have recourse to grants from the public fund were carried out it would probably give rise to many questions that would seriously interfere with the establishment of reciprocity throughout the three kingdoms. Doubtless, however, this subject will receive the careful consideration of our Council, and for the present, therefore, we refrain from further discussion of it.

YORKSHIRE COLLEGE OF SCIENCE.

At a General Meeting of the Council of the Yorkshire College of Science, held on Friday, July 24, Dr. T. E. Thorpe, F.R.S.E. was elected Professor of Chemistry.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July, 1874.

Present on the 8th, 9th, and 10th—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

On the 14th and 15th—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

On the 16th—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

On the 17th—Messrs. Allchin, Barnes, Benger, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

On the 20th—Messrs. Allchin, Barnes, Benger, Bottle, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor and Umney.

On the 21st—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

On the 22nd—Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

On the 23rd—Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Taylor, and Umney.

On the 24th—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 8th, 15th, 22nd, and 24th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Twenty candidates presented themselves for this examination. *Five* failed. The following *fifteen* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

	*Fairman, George Peters	London.
	*Whyte, Alexander	London.
	Symons, William Henry	Barnstaple.
	Hunt, Freeman William	London.
	Smith, Thomas James	Spalding.
	Collier, Henry	Chatteris.
	Compton, Arthur	Reigate.
	Cotterell, William Burbidge	Dover.
	Green, Thomas	Belfast.
	Thirlby, William Arthur	Ashby-de-la-Zouch.
	Aylesbury, William Thomas	Brighton.
	Hamond, Joseph	Peterborough.
	Norman, Joseph Slaughter	Royston.
	Thring, Edmund John Henry	Trowbridge.
	Kirkby, Robert	Ulverston.

MINOR EXAMINATION.

Three hundred and three candidates presented themselves for this examination. *Two hundred and thirteen* failed. The following *ninety* passed, and were declared qualified to be registered as Chemists and Druggists:—

	*Jones, Jabez Abraham	Birmingham.
	*Fowler, Thomas	Torrington.
	Ashbourne, Charles	Birmingham.
	Long, Theophilus H. Beavan	Brighton.
	Atmore, Edward Alfred	King's Lynn.
	Warriner, Charles William	Nottingham.
	Axford, John William	Coventry.
	Townend, Thomas Francis	Durham.
	Purvis, Thomas Alexander	Gosport.
Equal.	Brown, George German	Dresden.
	Hemingway, Edward	London.
	Lloyd, Rees	Dowlais.
Equal.	Bunn, Charles Grinling	Colchester.
	Miles, Charles John	Bristol.
	Wedge, George Deller	Alresford.
	Brend, Kenneth Benjamin	Swansea.
	Holmes, Alfred John	Preston.
Equal.	Catford, Obadiah William	Chard.
	Hayhoe, William	Diss.
	Pattrick, George	Long Sutton.
	Street, John Westrope	Melton-Mowbray.
Equal.	Coleman, Edward James	Cardiff.
	Garratt, Arthur	Guildford.
	Woolston, Thomas Henry	Faversham.
	Bamfield, John	Bristol.
Equal.	Owen, Phillip Nicholas	Carmarthen.
	Price, John	Swansea.
Equal.	Clifford, Richard Noon	Melton Mowbray.
	Mill, John Brown	Coventry.
Equal.	Cooke, Edmund Herbert	Northampton.
	Head, John	Waterfoot.
	Hues, William Richard	Everton.
Equal.	Beardsley, James	Nottingham.
	Pumphrey, John Henry	Evesham.
	Wilson, Griffith Phillips	Merthyr.
	Josling, Alfred	Chelmsford.
	Wilks, Robert	Skipton.
Equal.	Bailey, Richard John	Spalding.
	Tomlinson, Eldred Edward	Whitehaven.
Equal.	Ashmore, George Johnson	Lindsworth.
	Hodgkinson, Peter James	Congleton.
	Holmes, George	Sheffield.
	Perry, Edward Charles	Wareham.
	Pain, Edwin	Dover.
Equal.	Knight, William Tomlinson	Nottingham.
	Sampson, George	Chesterfield.
Equal.	Jerrett, Edward	Salisbury.
	Passmore, Charles Frederick	Kilburn.
	Bray, Ernest Edward	London.
Equal.	De Carle, Horace Edward	Norwich.
	Loadman, James	Liverpool.
	Stephenson, Robert	Bradford.
	Halse, Thomas	Tiverton.
Equal.	Duncalf, James Mills	Congleton.
	Owen, Rowland	Holyhead.
	Pritchard, Samuel Evan	Bangor.
	Tigar, Harwick Brigham	Beverley.
Equal.	Breese, Thomas	Norwich.
	Davis, Henry John	Newbury.
	Hall, Peter	Sunderland.
	Harston, John Frederick	Lincoln.
	Sneath, Thomas Dixon	Newark.
	Bathe, Frederick James	Chippenham.
	Wells, John	Sleaford.
	Morson, Thomas Pierre	London.
	Ewell, Richard Michael	Sandwich.
Equal.	Cuttle, Arthur Edward	Scarborough.
	Dear, Theophilus	Hornsey Rise.
	Garth, John	Preston.
	Jeffery, Henry Thomas	Tring.
Equal.	Hitchcock, James	Whittington Moor.
	Wigginton, Alfred	Islington.
	Davies, Arthur	Swansea.
	Legg, Henry Arthur	Kingsland.
Equal.	Hogg, Edward Grindle	Ealing.
	Padwick, William Guy	London.
	Waddington, Herbert	Thornton.
Equal.	Endle, Frederick	Barnstaple.
	Glyde, Henry Alfred	Bedford.
	Smithurst, John	Nottingham.
	Stedman, Harry Bernard	Bayswater.
Equal.	Gimson, Joseph	Leicester.
	Lloyd, David	Merthyr.
	Marrion, William	Oakengates.
	Read, John Henry	London.
	Ronchetti, Thomas Angelo	Stockton.
	Rowland, Edward Edisbury	Liverpool.
	Solomon, Charles Edwin	Penryn.
	Walton, David	Manchester.
	Kimber, Benjamin Tindall	Southampton.

The above names are arranged in order of merit.

* Passed with Honours.

PRELIMINARY EXAMINATION.

Certificates as undermentioned were received in lieu of the Society's Examination.

Certificates of the College of Preceptors.

Ashton, Henry ....Lynn.
Gantlett, Henry ....Wolverhampton.

Parliamentary and Law Proceedings.

SPECIAL REPORT OF THE SELECT COMMITTEE ON THE APOTHECARIES' LICENCES BILL.

Your Committee having examined witnesses on the general questions raised by the provisions in the Bill submitted to them, have agreed to the following report :—

That a great deficiency is admitted to exist in Ireland of shops for the sale of medicines and compounding of prescriptions, by which serious inconvenience is entailed on the public.

That this deficiency arises from the exclusive privileges enjoyed by the Apothecaries' Company, and from the high and consequently expensive standard of qualification which it has thought it necessary to maintain, in accordance with the view that an apothecary should prescribe as well as dispense medicines.

It was suggested to remedy this deficiency by extending to Ireland the operation of the Pharmaceutical Society of Great Britain as it has been extended to Scotland ; but your Committee recommend, in preference, the formation of a separate Pharmaceutical Society for Ireland, especially on the following grounds :—

a. That in Ireland there has been for many years a licensing centre for pharmacy. There was no similar institution in Scotland, at the date of the extension of the English Pharmaceutical Society to that country.

b. That a local centre will be more conducive to the scientific and professional development of pharmacy in Ireland, this effect having been found to result in the analogous cases of the medical and surgical schools.

c. That the evidence we have heard leads us to believe that there exist in Ireland ample materials for the creation and maintenance of a Pharmaceutical Society.

Your Committee, feeling how important it is that complete reciprocity should exist between the Pharmaceutical Societies of Great Britain and Ireland, recommend that the examinations and qualifications in each of the three kingdoms be identical ; the fees to be paid for examination, licence, and registration, be equal ; and that registered licentiates of each kingdom shall have equal rights and privileges in the three kingdoms respectively.

Your Committee further recommend the adoption of a common register for both Societies, and that both be subject to Government supervision.

Your Committee suggest the following as a scheme for creating a Pharmaceutical Society in Ireland, viz., that the Society be formed by naming, in the first place, a certain number of fit and proper persons to be foundation members ; with power to make bye-laws, lay down a scheme of examination, and appoint a Board of Examiners, subject to the approval of the Lord Lieutenant in Council.

That a first Board of Examiners be appointed, with representatives from certain scientific bodies, which have expressed their willingness to co-operate.

Your Committee are of opinion that the new Society should be independent of the control of any existing body.

That after a date to be hereinafter named, no person whose name is not on the register of the Pharmaceutical Society of Great Britain and Ireland (with the exception of the licentiates of the Apothecaries' Hall of Ireland) should be permitted to sell any of the articles scheduled or to be scheduled as poisons under the Sale of Poisons Act, Ireland, 1870 ; or to compound prescriptions containing any such articles.

That the restrictions and penalties on the sale or compounding of medicines or poisons contained in the Act 33 Geo. 3, c. 34, be abolished.

That the interests of existing traders affected by the foregoing resolutions as to the sale of poisons, should be protected.

It has been suggested to your Committee that the introduction into Ireland of men qualified by a shorter and less expensive process to practise as pharmacists would unjustly affect the interests of the licentiate apothecaries, who at present possess the exclusive right of so practising, and have obtained it by a longer and more expensive process.

It would appear, however, that the more expensive qualification also confers a more extended power of practice, with which it is not proposed to interfere ; and your Committee is of opinion that no such case of hardship would arise as to call for legislative interference.

Your Committee, in conclusion, report that it is not expedient to proceed further with the Bill referred to them ; but that, in their opinion, the Executive Government should at the earliest opportunity introduce into Parliament a measure framed in accordance with the resolutions in this report.

HOUSE OF COMMONS.

CO-OPERATIVE SUPPLY ASSOCIATIONS.

On Tuesday night, Sir Thomas Chambers called the attention of the House of Commons to the inexpediency of associations for trading purposes being established and conducted by *employés* of the Government, under the name of co-operative supply associations. He said he had no objection to the system of co-operation for the purpose of enabling a number of persons to facilitate the supply of their own wants, as distinguished from carrying on trade to supply the wants of those who did not form a portion of the body corporate. But it was felt by many persons that under the name of co-operative stores and civil service supply associations there had been a regular system of trading, and they wished the attention of the house to be called to the fact that under the name, guise, and pretext of co-operative associations, certain civil servants of the Crown had been carrying on a very large system of trading, which could not be distinguished from ordinary trading. These associations were not carried on on the principle on which co-operative associations were carried on. He held in his hand a document which had recently been issued, headed "Civil Service Supply Association, Limited," which showed the state of its affairs on the 28th February last. It stated that the total purchases of that establishment alone, during the half-year ending on the 28th February, amounted to £773,364 1*s.* 8½*d.*, and the total amount received from sales was £819,428 1*s.* 1*d.* The net profits for the half-year were over £9000, which, added to accumulated profits account of that institute, amounted to £90,000. He believed that the returns of all these societies together were upwards of £2,000,000, and that their profits were very large. The profits made by these associations were made in the way in which ordinary tradesmen or companies made their profits—not simply by selling at a price to cover the cost and distribution, but on the principle of selling some articles at a loss and others at a large profit. The association to which he referred consisted of 4500 members and 15,000 ticket-holders, who had the privilege of purchasing ; and at the last meeting a motion was to be made that the 15,000 ticket-holders should be increased to 30,000. They, therefore, were not co-operative but trading societies, set up in competition with retail tradesmen by the civil servants of the Crown, and ought properly to be called limited trading companies. The hon. member then drew attention to the prospectus of a society set up to displace the original civil service co-operative stores; which, after stating that the profits of the old society had been £90,000, went on to say that accumulation of profits so large was a direct infringement of the main principle of co-operation, which was that after paying all expenses and allowing a fair dividend for the capital employed, all the profits belonged to the purchasers. It stated that four-fifths of the original members (viz., 17,000) were ticket-holders, and proposed that they as well as shareholders should be entitled to the benefits of the new organisation; so that the large profits realised should be devoted to the customers, and not exclusively to the shareholders. The regulations, after all, were not co-operation but trade, and he could not see why her Majesty's civil servants should be allowed to set up this gigantic trading association against the efforts of individual shopkeepers. He had received a private letter from Dublin, date June 8, giving him a few notes respecting the doings of the only society of the kind in Ireland. It was established in 1862, and it well illustrated the temptations into which such societies not unnaturally fell. The first prospectus stated that civil servants, having only fixed and generally small salaries, found it difficult to meet the enhanced prices of every article of consumption in their families, and that therefore the articles of the association would be supplied at such a reduced rate as would only leave a narrow margin to cover the expenses. If that had been adhered to there would be nothing to complain of, but in less than a year the fundamental principle of the association was broken, through, and the temptation to make it a trading association was found to be irresistible. It appeared from the complaints of those who set them up that these associations had gone far beyond the original intention. That intention was no doubt justifiable, because it included the poorer civil servants; but now the poorer were excluded and the wealthier alone benefited. Again, it proposed to deal with the necessaries of life; but in the more modern forms every conceivable luxury was supplied from the stores. The Haymarket society, for instance, included amongst the customers it was founded to benefit, as stated in its prospectus, not only civil servants but peers, members of parliament, officers of naval and military rank, and clergymen. Indeed, to use the words of one of their own writers, the whole affair was now a gigantic sham, and there was nothing to distinguish them from ordinary trading societies. To the work of carrying on these societies a large number of gentlemen in the civil service devoted their time, which was contrary to the Queen's regulations. Public time was not unfrequently devoted by these gentlemen to the management of these societies, which, as he had stated, had transactions covering an outlay of £2,000,000 a year. Complaints had reached him of the way in which the canteen at Woolwich was conducted, and he had been informed that the canteen servants in uniform called on private person for orders and for the delivery of goods. There was only one other point on which he would trouble the house. The societies now not only supplied all the luxuries of life, but they made up physicians' prescriptions (a laugh), thereby acting in direct contravention of the laws relating to apothecaries. The house would, he thought, be of opinion that he had made out his case; but all he wanted was an assurance from the Government that all this was not done with the sanction and approval of the Government.

Mr. Forysth expressed his general concurrence in the views of his hon. and learned colleague. He wished the house to clearly understand that those who objected to these co-operative stores did so not because they denied the right of the civil servants to combine to buy things wholesale and sell them retail among themselves, but because civil servants had become shopkeepers on a gigantic scale, and were selling not only among themselves but also to the outside public. It was perfectly well known that these stores were not confined to the civil servants, but that they were conducted as commercial speculations. He himself knew of a case where £80,000 had been divided among the outside public. What the tradesmen said was, that these civil servants were the paid servants of the Crown, that the shopkeepers contributed towards those salaries, and that it was somewhat unfair that they should be allowed to compete with the regular shopkeepers. Another objection raised by the tradesmen was that the civil servants were supposed to devote their whole time and attention to the service of the State, and that it was an injustice to the public to allow them to become clerks, managers, and directors of these associations, where they employed time which, properly speaking, belonged to the state.

Mr. Macdonald said that this was, he believed, the first effort which had been made to put a stop to the thrift and providence of a large body of the people of London, and he did hope that the house would not countenance the attempt. It was contended that these civil service stores were not carried on on the co-operative system. He ventured to say that all which had been said against the civil service stores applied with equal force to all such stores throughout the country. At Rochdale, for instance, which was the home of the co-operative system, the principle had been acted upon from the commencement of allowing the general public to purchase in the stores. Nay, the promoters had even gone the length of giving a bonus to the public to induce them to purchase. That system had, in fact, been adopted throughout the entire country. When the civil service stores were complained of it ought to be borne in mind that, besides saving money, they were established to supply good, pure, and wholesome articles. There had been a system of adulteration and public poisoning going on for a long time, which the founders of the stores determined to put down, and it was being done effectually. If the regular dealers would supply good articles, and would be content with smaller profits, they would soon reclaim back their customers.

The Chancellor of the Exchequer said the hon. and learned member had made a very temperate statement, and had so commended the question to the attention of the house. But it ought to be borne in mind that the question was naturally one of very great difficulty, and one that was by no means free of embarrassment. For instance, in regard to one of the last points which the hon. and learned gentleman has mentioned—that relating to the sale of drugs—he (the Chancellor) might be permitted to make a suggestion which applied to the rest of the hon. and learned gentleman's argument. Undoubtedly, if the effect of selling drugs at stores was such as in any way to endanger the public interests in regard to matters which were of great importance, it must be observed that even were the Government to take strong measures, and were to put down these stores, there could be little doubt that the system which had been initiated, and which had proved such a financial success, would be at once taken up and worked by others. In that case the difficulties of which the hon. and learned gentleman had given them an illustration in the case of drugs would present themselves under another and a similar system of association. Therefore such difficulties, if at all, must be dealt with by some general system of legislation designed to prevent such abuses. They could not be dealt with simply by the interference of Government in the way of putting down these particular associations. Attention would be given to the subject, but if any legislation was felt to be necessary it would have to be proceeded with cautiously. He would say at once that the attention of the Government would be given to any matters of that sort in order to decide whether or not any remedies were required. But with regard to the general question of the carrying on of this system by the civil servants of the Crown, and as to whether the Government ought to interfere to prevent, limit, or regulate in any way that system, the house would perceive that two questions here arose of very considerable importance. The first was whether the tradesmen of the metropolis had a right to complain of the competition to which they were subjected by this system. He thought that the history of the co-operative movement seemed to prove that they had not. A number of the civil servants employed in the Post Office and elsewhere thought that they could provide themselves with certain articles at a cheaper and better rate than that at which they got them from their tradesmen. When they dealt with their tradesmen they found out that they were subject to many disadvantages. They were charged the highest price for articles, and the latter were found not to be of the best quality. Those high prices were charged in order that the bad debts might be covered which were contracted by the tradesmen under the credit system. They thought they would be protected from these evils by introducing among themselves a system of co-operation, founded upon the ready-money principle. No doubt it was a very great advantage to a large body of public servants that they should be able to supply themselves upon moderate terms, and upon a system which would prevent them running into debt. But when they established this system they were met by a counter movement on the part of certain of the retail traders, who endeavoured to crush the movement by inducing the manufacturers and wholesale dealers to refuse to trade with the gentlemen who had started the stores. The consequence was that the latter were compelled, acting upon the principle of self-defence, to extend their system and bring in a number of outside customers. The hon. and learned gentleman said these stores had become trading societies. That was a matter with which they had very little to do. He, for one, did not see where the line was to be drawn, or how they were to say that co-operation, within certain limits, was reasonable, but beyond those limits was unreasonable. But then there was another side of the question, and one which raised considerations of extreme difficulty. That was not so much the political or the economical question as the question of the administration of the public service. Here also arose a very difficult point for consideration, and that was how far public servants ought to be allowed by Government to embark in business of a remunerative character outside and beyond their own duties. He confessed that was a matter which had often caused him considerable anxiety, and it was one upon which he had not even yet come to a clear and definite conclusion. No doubt it could be contended that you engaged the services of those gentlemen, that you paid them for their time, that their time ought to be given up to you, and that it was an abuse to allow them to employ their time carrying on business on their own account. Well, if they laid down that doctrine they must apply it not only to civil servants who traded, but to civil servants who embarked in any other kind of extra employment. Much undoubtedly could be said on that point also. Between these views of the question it was very difficult to decide. He was anxious not to come to any definitive conclusion at present, the more especially as the whole question of the reorganisation of the civil service was under review. A commission was sitting which might soon be able to report, and which report might likely contain some very valuable suggestions. All, therefore, he would now say was that he admitted there was a great deal in the argument which had been brought forward by the hon. and learned member. On the other hand it was manifestly an advantage to the whole country that the civil servants should be able to supply themselves with cheap and pure articles. He would promise that the attention of the Government should be devoted to the subject.

Poisoning by Oxalic Acid.

Mr. Bedford held an inquest, on Monday, at Westminster Hotel, on the body of a man named John Stevens, aged 67. It appeared that at 7.30 on Saturday morning last the deceased walked into the hall of Westminster Hospital, and addressing the night porter, said he had taken poison, because he wanted to die, for he was a wicked man. He appeared to be quite sober and sensible. The porter at once called Mr. Parkhouse, the house-physician, who attended immediately, and to whom the deceased said he had taken a quantity of oxalic acid, handing him at the same time a paper packet which had contained oxalic acid and was marked "poison" on the outside, adding that he had taken the poison in its solid state in Peter Street, close by the hospital. The usual remedies were at once applied, but did not appear to have any effect, the deceased became pulseless and sank in a state of collapse, dying in less than an hour after coming to the hospital. Mr. Parkhouse said he had made a *post-mortem* examination of the body, which was well nourished. The gullet and stomach of the deceased was highly inflamed and corroded from the action of an irritant poison. The symptoms were such as would be produced by oxalic acid. He had no doubt the deceased died from this cause. The clothes worn by the deceased at the time of his death have been searched, but nothing was found to give any clue to his friends. The jury returned a verdict in accordance with the medical evidence.

Attempting Poisoning by Vermin Killer.

At the Summer Assizes, at Lancaster, on Saturday last, Charles Stansfield, plumber, was charged, before Mr. Justice Archibald, with astempting to administer poison at Fleetwood, on the 15th of March last, to his wife, Mary Stansfield, with intent to murder her.

Mr. Addison conducted the prosecution; the prisoner defended himself at great length.

It appeared that the prisoner and his wife were living with her parents, and that his wife had charged him with going with some other woman. On the 9th of March he purchased a packet of vermin powder, telling the shopkeeper his mother-in-law wanted it to kill rats with. He also told a friend that he would probably never see him again, and bade him good-bye. On the evening of Sunday, the 15th, the prisoner brought in a quart of beer for supper. His wife got out two teacups and he then filled both cups, one for each. While she was drinking he said, "Take a good drink as I do." He then asked her to go for some coals, but she refused until she had had her supper. He then asked her to do something else, and eventually at his request she went for some cake in the pantry. She took the candle with her, leaving him in the dark, and as she went she heard a rustling of paper. On her return she noticed he had her cup in his right hand and the jug in his left. He put down the cup where it stood before, and she then noticed some green powder on the top of the beer. She asked what he had put in the beer, and he replied, "Nothing." He then took the cup and emptied the beer into the ashes. She noticed some powder on the table and on a knife, and asked what it was. He said it was nothing, and wiped it away. She then charged him with trying to poison her, and called out for her mother, who came downstairs. However, the prisoner and his wife went to bed together, and it was not till next day, when the sediment in the cup had been analysed and found to be strychnine, that her father turned him out of the house. The prisoner, on being charged by the police, said he had put no poison into the cup. It was only jalap, and he gave it her because he knew she was bound in her body, and he thought it would do her good. Afterwards he said he was so much troubled about the young woman his wife was jealous of, that he meant to put an end to himself, and the poison was meant for himself and not for her, and he was in the act of drinking it when his wife found him with her cup in his hand. The prisoner had prepared a long list of questions for cross-examination, and also an ingenious speech which he read at great length, but the jury found him *Guilty*, and sentence was deferred.—*Times.*

Reviews.

A MANUAL OF BOTANY, ANATOMICAL AND PHYSIOLOGICAL, FOR THE USE OF STUDENTS. By ROBERT BROWN, M.A., etc., Lecturer on Botany. Edinburgh: William Blackwood and Sons. 1874.

Of the writing of botanical text-books there appears to be no end; and it will be acknowledged that the reasons ought to be very cogent which bring forward one more competitor into the field. Whether in the present case the *raison d'être* is sufficiently obvious is a question on which opinions will probably differ. The plan pursued by the author of the present volume is, in one respect, a novel one, in support of which much may be said. The ground occupied by the science is now so vast, the number of separate facts to be described so enormous, that the attempt to compress even the outlines of the whole into a single volume of moderate size and within reach of the ordinary student in the matter of price, often signally fails. Mr. Brown accordingly treats on the present occasion only of the anatomy and physiology of flowering plants, leaving to another volume the systematic and geographical department, in which will also be included the anatomy and physiology of cryptogams.

Turning first of all to the later portion of the volume, we find many of the subjects treated of more copiously than in other works of a similar character. The phenomena of fertilization, vegetable irritability, etc., are described in detail; and all the most recent publications appear to have been carefully consulted so as to give a *resumé* of the state of our knowledge to the present time. The copious references to the original sources of information will be very useful to the student who wishes to pursue special branches. Of the earlier portion we cannot speak with the same unqualified praise, the author having apparently drawn his statements from a great variety of sources, often evidently without testing their accuracy, and sometimes apparently without even understanding their meaning. The work is disfigured by too many typographical errors; and we must take serious exception to such descriptions as that of stomata as "anomalous cells," and of the "intercellular substance" as if it were something of altogether different origin to the cell-wall itself,—defects which thrust themselves upon us in the first two pages. The chapter on the ultimate constituents of plants contains a large amount of information that will be useful to the student; though even here we find statements which have apparently been inserted without sufficient care; as, for instance, that sodium is "invariably found in all plants," which is not in accordance with the most trustworthy observations; and the somewhat astonishing assertion that carbon "forms, on an average, about one-half of our edible vegetables"!—a statement which would somewhat perplex the student who is told, two pages further on, that 90 per cent. of cabbage, 75 per cent. of potato-tubers, and 91 per cent. of turnips, consist of water. Altogether we do not see that Mr. Brown's Manual is likely to supplant those already in existence.

MANUAL OF BRITISH BOTANY; containing the Flowering Plants and Ferns, arranged according to Natural Orders. By C. C. BABINGTON, M.A., F.R.S., etc. Seventh Edition, corrected throughout. London: J. Van Voorst, 1874.

We have here to welcome the re-appearance of an old friend. Among all its competitors, "Babington" has probably kept its place as the most trusted and widely-used field-companion of the botanist, the work from which the largest number of students have derived their knowledge of the characters of British plants. The portable size, especially of the thin paper edition, and the convenient practice of putting in italics the few words which describe the character by which the species is most readily distinguished from the other species of the genus, have no doubt contributed to this result. Criticism on so well known a work there is hardly room for. Great pains seem to have been taken in keeping it up to our constantly advancing knowledge of British botany, in the addition of newly discovered species and varieties. Several of the larger and more difficult genera, such as *Rosa*, *Rubus*, and *Salix*, have been carefully revised, and the position has been altered of a few genera and species. If it is worth while to allude at all to so trivial a point, it seems a pity that some uniformity cannot be adopted in the use of the terms "rare," "common," and so forth. To take the first page at which we happen to open the book. The locality of *Ajuga reptans* is given as "wet places," and of *A. Chamæpitys* as "sandy and chalky fields;" there being no indication to the young plant-hunter that the former is a plant which he will find almost universally distributed, while he may botanize for years and years without coming across the pretty and rare "ground pine." Precisely the same description is indeed given of the habitat of so widely distributed a plant as *Lamium amplexicaule*, which is, however, by no means confined to "sandy and chalky fields." Again, why is *Senebiera Coronopus* called "common," when the same term is not applied to *Lamium album* or *purpureum?* It would greatly assist the collector if numbers were affixed to the description of each plant to indicate its comparative rarity, such as those employed in the London Catalogue. He will there find the distribution of *Lamium purpureum* indicated by 100, *Ajuga reptans* 90, *L. amplexicaule* 80, *L. album* and *Senebiera Coronopus* 70, *Marrubium Vulgare*, (styled "rare" in Babington,) 40 (?), whilst *Ajuga Chamæpitys* is as low as 10. Why, again, is the honour of indigenousness denied, edition after edition, to *Teucrium Botrys*, which is admitted to be native by every one who has seen it growing in its habitat near Box Hill, and the geographical distribution of which would entitle one to expect that it should be found in Britain? These, however, are microscopic criticisms on a most admirable and useful work.

A TREATISE ON PHARMACY, designed as a Text Book for the Student and as a Guide for the Physician and Pharmacist, etc. By EDWARD PARRISH. Fourth Edition, enlarged and revised by THOMAS S. WIEGAND. With 280 Illustrations. London: Baillière, Tindall and Cox. 1874. From the Publishers.

Obituary.

THOMAS STANDRING.

We regret to have to announce the death of Mr. Thomas Standring, Pharmaceutical Chemist, late of Piccadilly, Manchester, who was one of the earliest members of the Pharmaceutical Society, and during many years promoted its interests as a member of Council.

The late Mr. Standring served his apprenticeship with Mr. Halkyard, an apothecary in Piccadilly, Manchester, to whose business he succeeded; but about forty-two years ago he purchased the business of Mr. Goulter, No. 1, in the same street, to which he removed and he carried it on successfully until within the last seven or eight years, when he ceased to take any active part, and left the management in the hands of his son, Mr. John Standring, who had been partner with him for some time.

Mr. Standring was one of the visiting apothecaries to the Royal Infirmary for nearly forty years, and the flag of that institution was hoisted half-mast when his death was announced. He always took an active and leading part in any matters connected with the interests of the trade, and was generally chosen president or chairman of the various associations which were formed from time to time amongst the chemists and druggists of Manchester; those only who were intimately associated with him on such occasions knew the amount of time and trouble he devoted to the work, and the liberality and kindly feeling he displayed.

Mr. Standring had been subject for some years to a bronchial affection, and had latterly resided at Southport, for the benefit of the milder climate and the sea-air. He had been staying at Buxton for a few weeks, and appeared much better in health than usual, until Saturday night, the 18th ult., when he was seized with an attack of vomiting, which, becoming serious, his medical attendant was sent for. But medicine was of no avail; a stoppage of the bowels had taken place, which could not be overcome, and he died on the 21st ult., at the age of 72, in the presence of several members of his family, free from pain, and in full possession of his faculties to the last. He was buried at Monton, near Eccles, on Saturday last.

Mr. Standring was first elected to the Council in 1847, and retained his seat for two years. In 1858 he was again elected, and served for three years consecutively, In 1862 he commenced a fresh term of office, which lasted until May, 1869.

Notice has also been received of the death of the following:—

On the 18th July, 1874, Mr. William George Davies, Pharmaceutical Chemist, of Commercial Road, London. Mr. Davies had been a member of the Pharmaceutical Society since 1860.

On the 1st July, 1874, Mr. Thomas Illingworth Holgate, Chemist and Druggist, of Bradford.

Notes and Queries.

GLYCEROLE OF ASSAFŒTIDA.—In order to avoid the tedious and disagreeable operation of rubbing together the assafœtida and water for the mistura assafœtidæ of the U. S. Pharmacopœia, Mr. J. W. Wood suggests (*Amer. Journ. Pharm.*, July, p. 309) forming a solution, or at least suspending the gum resin in a certain proportion of pure glycerine, which mixture could be diluted and used as required. The formula he proposes is as follows:—

Picked Assafœtida	℥ij
Pure Glycerine	℥ij

Cut the assaœftida into small pieces, and together with the glycerine subject it to a moderate heat in a capsule, constantly stirring and triturating with a pestle. In a short time the solution will be effected, and the result will be a liquid, not too thick for easy manipulation, each troy drachm of which will represent fifteen grains of the gum resin.

To prepare, say, four ounces of mistura assafœtida, add to four drachms (troy) of this glycerole sufficient water to make up the measure, shake them together, and the result, Mr. Wood states, is a handsome preparation much less susceptible to change than the official mixture. It is necessary in preparing the glycerole to guard against employing too great a degree of heat, so that the volatile oil may not be dissipated.

A similar method to the foregoing might be employed in the preparation of mistura ammoniaci.

ADULTERATION ACT, 1872.—REPORT OF THE SELECT COMMITTEE.

Sir,—As the result of a preliminary meeting of public analysts, held yesterday, we are directed to announce that a general meeting of the public analysts of the United Kingdom will be held on Friday, August 7th, at the Cannon Street Hotel, at 4 p.m., with a view to the formation of a society for mutual assistance and co-operation. The chair will be taken by Professor Redwood.

Circulars notifying this meeting are sent this day to all public analysts whose addresses are known, but if any are accidentally omitted, the announcement of the meeting in your columns will supply the omission, and we shall be happy to furnish all particulars to any gentleman who will communicate with us.

CHARLES HEISCH, } Hon. Secs.,
G. W. WIGNER, } *pro tem.*

79, *Great Tower Street, London,*
July 29th, 1874.

EXCESSIVE LABOUR IN PHARMACY.

Sir,—I have observed with pleasure that this subject is again being discussed in the Journal, as I was very much surprised and disappointed at the action taken by the Council in resolving to oppose Sir J. Lubbock's Bill, more especially as some of them stated they were in favour of fewer hours, which statement seemed to me altogether antagonistic to their action in opposing the Bill, which would have given them such.

I can understand those who approve of excessive hours of business doing so, but that the Members of the Council and yourself, who are in favour of fewer hours, should oppose the Bill, which would make earlier closing universal, and thereby prevent any special hardship, is to me inexplicable.

Without imputing anything like interested motives, it must be borne in mind that neither of you feel the pressure of the excessive labour, the Council being composed of gentlemen who are able to employ several assistants to do their business, and consequently cannot feel that amount of sympathy and interest in this matter that those do who have to bear its burden and pressure.

If it be right and advantageous alike to employer and employee that shops should be closed earlier, why oppose it? I very much fear that unless such a measure is adopted by the Legislature, early closing will never become universal, as there are in almost every town some members of the trade, both crotchety and selfish, who would oppose anything tending to shorten the hours of business.

In several cases which have come under my own observation, I have noted that even where agreements have been entered into to close earlier, as it has been optional, the selfishness of one or two has broken through the engagement.

For about six months the shops in Looe were closed on Thursdays at five o'clock, and it caused no loss to ourselves or inconvenience to the public, but was highly approved of by both; indeed, it seemed to ourselves like the beginning of a new life. Unfortunately, one of the drapers refused to continue, and consequently it was discontinued, although the members of our own trade were willing and anxious to do so; but, one being an outfitter as well, feared it would interfere with his business.

If Sir J. Lubbock's Bill had become law the selfishness of our neighbour would not have hindered and prevented the pleasure of the rest of us; not being so, however, it happened with us, as in the days of the wise man, that "one sinner destroyed much good."

While strongly urging endeavours to be made to induce a voluntary earlier closing, still more strongly would I urge the Council to reconsider the matter, and support Sir J. Lubbock's Bill, feeling assured that nothing less will meet this matter in its entirety. I would also urge all who are interested to write to their Members of Parliament, when the Bill is again introduced, asking them to support it.

The Council have not been very reluctant to apply for Parliamentary powers in other matters, and if it was right then, why object to Parliamentary interference when it will be attended with very great advantage to large numbers.

Of course, as you say, it will cause some amount of inconvenience; so has former legislation to a great many. Some of us, however, are so accustomed to inconvenience, that it does not trouble us very much, and it is to be hoped that we have learnt of two evils to choose the least, more especially as the inconvenience would only be of a temporary nature. The public would soon become accustomed to the earlier closing and make their arrangements accordingly.

To say a word as to the necessity and advantage of early closing seems to me unnecessary, as I have found in the course of my experience, both in London and provincial towns, very great regret expressed at the excessive and unnecessary hours of business, and the fact that it is already adopted in some towns shows it to be practicable.

I have been surprised to see the statements made respecting the salaries obtained by chemists' assistants. £50 or £60 per annum, indoors, is not a large amount, it is true, but if any man who understands his business works for less, he is, I think, acting very foolishly.

Twelve years since, when not 23 years of age, my salary in London was more than that indoors, and assistants are not so plentiful now as they were then. The comparison between the position of a joiner and chemist's assistant seems to me most anomalous, inasmuch as a joiner has not much opportunity of raising himself to a higher position, whereas any chemist's assistant can do so if he chooses to take the trouble.

JAMES S. HICKS.

Looe, July 27, 1874.

Sir,—It is very consolatory to me to observe that I am not the only pharmaceutist crying aloud over his grievances. From the correspondence which has recently appeared it may be inferred that what I complained of in my first two letters was not a particular, but a general grievance, and our troubles seeming now to have reached their highest point, our united efforts and a determined will are all that are required to remove them.

The Editor seems to espouse Mr. Cardell's suggestion, "To act according to what the majority of chemists wish should be done in the matter," and hints that, instead of supporting Sir J. Lubbock's Bill, we should put our shoulders to the wheel and get the waggon out of the rut ourselves—advice which cannot be put into practice, since past experience has proved it.

My senior partner tells me that, forty years since, it was agreed by the chemists here to close earlier, as well as to raise the prices of drugs. One chemist acted as a spy upon the others, and sent a messenger round the town, to notice which of them kept open longer, or sold their goods at a lower price than they had agreed to. There was no fidelity amongst our brethren then, and the whole scheme soon fell to the ground. The same remark may be repeated now, and I might give several instances to maintain it. One part of Mr. Cardell's plan is therefore impracticable. "As it was in the beginning, is now," etc.

There are three means by which we might do all we require. They are :—

The Pharmaceutical Society.
The formation of a trade's-union.
Sir J. Lubbock's Bill.

And why should we not expect our Council to take active steps to raise our position, and grant us our freedom? I went to the door of our Alma Mater and knocked. I was distressed, hard-worked, underpaid, and asked for help. Notice the answer she gave me—"This is a matter not purely pharmaceutical; I cannot receive you." Soon afterwards, however, I visited her again, more distressed than ever, and we all now see her answer—"The exertion of personal influence and example." Possible to the majority of us, but only in small things, and therefore driving us to extremities, to form a trade's-union, to rekindle the spark of secession, or perhaps do something as bad.

And have we no right to ask her attention to our wants! She is our legitimate parent, and ought to hear, as well as to appease, our wailings.

But it may be that a trade's-union would do more in every way than the Society has yet done for us. It would bring us prominently before the world as a class of workers entitled to respect and remuneration. We might expect then eight hours instead of twelve or fourteen, our ordinary day of labour, also "a fair day's wage for a fair day's work," which is certainly what we have not yet arrived at. The "rattening," however, the only drawback, would be unbecoming of good men.

Without putting ourselves to the trouble of canvassing in towns, in order to make an arrangement which past experience has taught us will be ephemeral, let us all agree to invite Sir J. Lubbock's Bill, which will make us all equal. I hold fast to the belief that nothing else will protect us from excessive labour. A clause to be inserted, whereby medicines only should be supplied after what any reasonable person would consider a fair day's labour for men engaged in a very responsible and learned profession.

I have no doubt Sir J. Lubbock has had his attention drawn to our complaints. How his heart will pulsate, and what stimulus will he receive merely at the prospect of casting his Bill to those who are actually yearning for it!

A COUNTRY MAJOR ASSOCIATE.

Sir,—I have been in the drug trade since 1840 (as assistant and master), and although not prepared to say that things are perfectly satisfactory as regards either the hours or the pay, perhaps you will allow me to answer from pretty extensive experience the questions of Mr. Cardell. What are the prospects in your trade? To a youth with a cultivated taste, desirous of acquiring knowledge, and willing to practise the necessary amount of self-denial, learning, position, respectability, and for the amount of capital employed, as good a return as almost any other occupation.

What are the drawbacks? The following among others :—That although it be honestly and faithfully pointed out to a youth on his offering himself for apprenticeship the absolute necessity for thoughtful and studious habits, and though every effort be made by the employer to render facilities for study and improvement, still by far the greater number refuse to avail themselves of the advantages offered, and having served an apprenticeship of four or five years with the minimum of study and the maximum of neglect, they are obliged either to take an inferior situation or to get into a good shop as improver, at a low salary, and even then are often dear enough.

And, further, numbers of them having but little capital, and less ambition, if they can but manage to squeeze through an examination; they fill the outskirts of our towns and cities, ruining prices, and keeping up late hours.

For this class the drug trade holds out but little encouragement, but for a young man who is determined to do his best, the "good time" spoken of may be hopefully looked for. Putting aside the exceptional cases and extravagant statements that appear in your last impression, any person who will look at things fairly must admit that great improvements have taken place. A few weeks ago I happened to be in a large city on the Sunday, and although wanting an article rather urgently, went through street after street before I found a shop with the door open. Ten or twelve years ago the door-shutter would have been down in almost every case.

In the town where I reside are forty chemists: ten years ago almost every one was open all day Sunday; now there is only one. The week-day hours are also shorter, and greater time allowed for study. For study, my young men have from two to three hours every evening: and for recreation, etc., the whole of the Sunday, one afternoon and two evenings every week.

In time we may see greater advances still; but I am afraid it will be a long while before either masters or assistants will be able to calculate a great pay, and little or no work.

As "*Vir pro bono publico*" says, the assistant (if good for anything) has the best chance, he can select his place, make his own terms, and leave when he likes.

There has been this grumbling about salaries for years. Surely many of these underpaid ones must have become masters themselves. Why have they not acted upon their convictions, and paid better?

There are many matters in the trade that require improvement, but they are mostly of a local character, and can never be met by any general rules or regulations.

There must be mutual forbearance and consideration between employers and employed. Nothing can be done without this. As to driving us to close our shops at seven o'clock regardless of all consequences, that is what many of us could not do. If we are to put up our shutters every evening at seven, and let our hands leave whilst we stay at home to meet every demand and supply every emergency, the drug trade would indeed be a greater slavery than it has ever yet been in its worst times. What sort of respect or feeling could an employer have for those who would treat him in such a churlish spirit? This is not a contest between capital and labour, and to find those who ought to be gentlemen talking of striking, is offensive to one's better feelings.

Let the trade, in each city and town, casting aside all petty jealousies, combine together and labour for the common good, in regulating prices, shortening the hours of business (as much as practicable), and in giving all reasonable time for study and recreation. Much more than has yet been done may be accomplished, and the advantage of this system will be, that instead of ill-feeling being excited, good feeling and respect will be promoted amongst all. If your complainers will leave extravagance and bombast for a while, and unitedly conferring in each town and city upon these evils, will call upon the trade generally, and temperately and calmly state their grievances, and how they propose to remedy them, they will, I believe, meet with a patient hearing. Most of us hate unnecessarily long hours as much as they possibly can do, but these things cannot all be set right by a few strokes of the pen written without much thought and less consideration, and mostly by those who have little merit to boast.

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

Sir,—If I am not treading ground that has already been gone over, I shall thank you to give me space for what I consider to be our real drawback, both in relation to status and remuneration; and while there is some pharmaceutical legislation in process of enactment for the sister isle, might we not, as a body, petition Parliament for the repeal of the Amendment, 1869, of the 1868 Pharmacy Act? I see comparatively little good resulting from the 1868 Pharmacy Act, while medical men have still the right to compound their own drugs. I never saw yet that chemists or the public had to fear the neighbouring grocer retailing a few "simples." It is the men who practise physic and pharmacy who are the real clog to our advancement. Repeal the 1869 Amendment and we will want neither candidates for our examinations, nor a fair guerdon for our responsible services.

Neston. N. P. LEWIS, M.P.S.

EVENING CLASSES FOR PHARMACEUTICAL STUDENTS.

Sir,—Having but recently come up from the country, where comparatively few opportunities are afforded young men, I expected to find in London evening classes or lectures, where those engaged during the day could meet for the purpose of instruction; but in this I, like others, have been disappointed. However, as this is a want that can be supplied, perhaps you will kindly allow me a short space in your columns, wherein I may express my views, hoping that others more capable of taking the lead may be stimulated into action.

All who have pharmaceutical progress at heart cannot but have due regard for the School of Pharmacy at Bloomsbury Square, and every one able to do so should avail himself of the advantages offered there, but still it cannot be denied that the majority of us young men are so situated as to be unable to derive any direct benefit from that institution.

To meet this deficiency I would suggest to the Council the desirability of instituting evening classes, at the Square, say, meeting twice a week, once for chemistry, and once for materia medica, not for the purpose of cram, but to instruct those desirous of obtaining sound knowledge.

There is every reason to believe that the plan would prove a success, provided it be well organized, and not overweighted, as we have an abundant supply of gentlemen quite capable of undertaking the work of conducting these classes.

I cannot but feel that any good scheme calculated to improve the present state of things should command our best support.

E. EVANS.

60, *St. George's Road, S.W.*

"OIL OF CINNAMON OR CASSIA."

Sir,—May I ask Dr Porter Smith whether the statement that the oil which he thus designates* is obtained from the "leaves and twigs of the cassia-tree," is the result of his own observation?

Also in what work or trade-list any mention can be found of the *Oleum Malabathri* of commerce?

DANIEL HANBURY.

"*Alpha.*"—By adding to an aqueous solution of nitrate or chloride of cobalt sufficient sesqui-carbonate of ammonia to dissolve the precipitate at first formed.

W. Pail horp.—The information is contained in most modern works on arithmetic.

W. T. Elliott.—The elixir mentioned is a proprietary preparation concerning which we are unable to supply you with any information.

A. K.—We do not think that, with the present demand for capable assistants, there would be much difficulty in one obtaining an engagement upon more favourable terms than those mentioned in your communication.

R. B. S.—It is not advisable, in studying any subject, to confine your reading to any one author. With this proviso the book you say you are using is a good one for the purpose.

"*Nestor.*"—(1) Antiseptic properties have been attributed to hydrate of chloral, but we do not know that it has been suggested as a preservative for butcher's meat. (2) We are not qualified to say. (3) A Bill to modify some of the restrictions under which the examinations of the Apothecaries' Company are conducted. (4) "Care should be taken of health."

"*Associate.*"—In section 1 of the Bye-laws, clause 18, it is provided, that Associates being in business on their own account, and desirous of continuing Associates, "shall give notice to the secretary on that behalf, and shall contribute to the funds of the Society the same subscriptions as members, and in default thereof shall cease to be Associates."

M. Thompson.—A post-card, to which one of your labels is affixed (thus incurring charge for deficient postage), has been received, but we are unable to guess to what it refers.

H. O. Brown.—The Latin subject for the Preliminary Examination in October next will be Latin Grammar, and the translation into English of a paragraph from the first book of Cæsar, or a passage from each of the following works: 'Pereira's Selecta è Præscriptis,' and the last edition (Latin) of the London Pharmacopœia. After the 31st December, 1874, the medical Latin will be discontinued.

"*Aq.*"—Probably, as you suggest, the sandstone contains deposits of gypsum.

"*Dandie Dinmont.*"—We are unable to comply with your request to reproduce the regulations as to Dispensers in Her Majesty's Naval Hospitals (printed in vol. iii p. 364); but it may answer your purpose to state that application for the office must be made, in writing, to the Director-General of the Medical Department of the Navy; that the applicant must not be less than 20 nor more than 25 years of age; and that he must possess the Major or Minor qualification of the Pharmaceutical Society. There is no stipulation as to marriage; and pay and allowances depend upon length of service and rank. The only way of obtaining employment as a dispenser in the army appears to be by enlisting in the Army Hospital Corps as a soldier; upon attaining the rank of sergeant, if qualified, and the post were vacant, you would be eligible to be employed as a compounder of medicine.

J. Williams.—We are unable to give you the opinion asked for, but would reccommend you to consult a dealer in druggists' sundries.

S. B.—See the articles on the drying of drugs in Proctor's 'Lectures on Practical Pharmacy,' or Parrish's 'Practical Pharmacy.'

"*Buck.*"—(1) *Hypericum androsæmium.* (2) *Allium oleraceum.* (3) *Rheum partense* var *nodosum.* (4) *Serrafalcus mollis.*

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. Durrant, Mr. A. W. Bennett, Mr. H. O. Brown, Mr W. Wickham, Mr. D. MacRitchie, "Aureoline," D. J., A. K.

* PHARM. JOURN., July 25, p. 61.

BRITISH PHARMACEUTICAL CONFERENCE DINNER.

The annual dinner was held at the Terminus Hotel, Cannon Street, on Thursday, August 6th, 1874, T. B. Groves, Esq., of Weymouth, president, in the chair.

Covers were laid for 150 of the members, who sat down to a most pleasant repast, served in the most admirable manner. During dinner the band of the Coldstream Guards played a selection of music, and the evening was enlivened by the singing of several glees and songs, under the direction of Mr. Winn.

After dinner the President rose, and proposed the usual loyal toasts of "The Queen," "The Prince and Princess of Wales, and the rest of the Royal Family," observing that, although they were sometimes called formal toasts, he entirely disagreed with that expression, for, with regard to himself, as also with regard to the members, nothing could be less formal. He was sure they would drink with the greatest enthusiasm, and with a hearty love, to the health of the lady who presides as head over our civil and religious institutions, and to whom we owe so many of the blessings we enjoy. The toast of "The Prince and Princess of Wales, and the rest of the Royal Family" was next in popularity to that of "The Queen," and there was no royal family in Europe, or in the world, who were so deservedly esteemed and beloved.

Professor Tichborne, of Dublin (who on rising was greeted with loud cheers), said that, as one of the oldest members of the British Pharmaceutical Conference, he claimed the privilege of proposing a toast which he was sure would be well received in that room, for he looked upon it as the most important toast of the evening, after that of the Queen. It was, "Prosperity to the Pharmaceutical Society of Great Britain," and, as a member of the British Pharmaceutical Conference, he felt that he was privileged to speak in a double capacity, as it were. They must bear in mind that in drinking the health of the British Pharmaceutical Society, they were actually drinking their own health, because the Conference was the offspring and child of the Society. If the Conference had not been nursed and cared for in the way it had, it could not have risen to its present high and happy position. Therefore, when he looked around him and saw the great success of that meeting, he felt it was not only a compliment to the British Pharmaceutical Conference, but indirectly a compliment to the British Pharmaceutical Society. The British Pharmaceutical Conference was, as he had observed, the offspring of the British Pharmaceutical Society, and as they had got into the nursery, they might carry it a little further, and consider the Pharmaceutical Society as a growing institution. It was a young institution itself, but it was one of the most prosperous institutions of the kingdom. He sincerely hoped and trusted that it would progress still more, and not get indolent from the apathy which might possibly be created by its great success, but that it would always carefully foster and tend the education of pharmacists. He hoped in the future to see the Society grow greater, and that the future generation—for they must recollect that not till the present generation had passed away would they get the generation that truly represented the work of the Pharmaceutical Society of Great Britain—would place themselves not only on a par, but in advance of all the countries of the world, France and everywhere else, and that they would be looked up to, as *par excellence* the Society which had encouraged and fostered pharmacy. He would not inflict upon them a long speech, for he was not given to long speeches, unless he had something very definite to talk about, and although the toast was one which would be a luxuriant subject to dwell on, he felt he need only commend it to them, coupling with it the name of T. H. Hills, Esq., the president, to ensure its most hearty acceptance.

The toast was drunk with honours.

T. H. Hills, Esq., the president (who was greeted with hearty cheers) thanked the members for the very kind manner they had received the toast of Professor Tichborne, and the professor for the way in which he had proposed it. He thanked them very much when they said he was a jolly good fellow. He felt he did not deserve it, but that he ought to do so after the kind and flattering reception they had given him. He would not appropriate their kind expressions to himself, though they had expressed them, he supposed, because he had taken great interest in the Pharmaceutical Society of Great Britain. He believed they did like men who were taking a deep interest in an association which was striving and doing all it possibly could for the advancement and education and prosperity of the chemists and druggists of England; and if there was anything he might lay claim to, it was that he did all in his power to advance and further the interests of those who were connected with the Pharmaceutical Society. Having said that, he would add he felt it was a very great honour for him to be placed in the position of vice-president; he felt very proud of it. Their meeting, he was sure, would do them a great deal of good and advance the best interests of the Society, for they had received their friends, and tried to make them as much at home as they could. They had welcomed them with their hearts and arms, and he must confess that it made him feel proud that he belonged to such a Society, when he heard the papers that were read both at the Society's meetings and at the Conference to-day. He supposed those who were members of the Conference were also Members of the Society, and he would say if they were not they ought to be. He was glad to be able to address them in that double capacity, and would remind them all that there was still a great deal to be done. He was, he believed, the first Associate of the Society, and he felt proud in saying it, and he had watched the Society from its commencement. He heard of what was going on at the Crown and Anchor, at the meeting there, when they were likely to be extinguished, and he had seen the Society grow to the exalted position it now occupies. That being the case, he felt most pleased that the Conference had met in London, and he was delighted to meet with Professor Tichborne from Dublin, because he would see what was done, and would be able to report when he went back in such a way that he trusted it would end in their becoming one Society for the United Kingdom.

Mr. Young, of Edinburgh, said that he was surprised on coming into the room to be told there was a toast which he was to propose, and although he had used all the arguments he could to persuade Mr. Carteighe that he was not the man to do it, and that there were others far more able, yet his arguments had all been answered, and he had to propose what, in his opinion, was really the toast of the evening. He should have liked an hour's consideration before speaking on it. He had listened to the speech of Professor Tichborne, and he was very pleased to hear him say that the toast he had to propose was, in reality, that of themselves. If that was so with the toast of Professor Tichborne, it was still more so the case with his, which was that of "Prosperity to the British Pharmaceutical Conference." When the Conference was first started he feared it might in some measure be antagonistic to the Pharmaceutical Society. However, time had gone on, and all his fears and doubts had been very much overcome by the way in which the Executive had conducted its affairs, and he was sure when they looked at the names of those whom the Conference had chosen during the period it had been in existence, from the name of Henry Deane, its first president, and others who had presided over them, down to the present time, they would agree with him, that if the Con[illegible] bearers such gentlem[illegible] would have every reason to be proud of it as the offspring of the British Pharmaceutical Society. He hoped it would go on and prosper. He wished to couple with the toast the name of T. B. Groves, Esq., its president, to whose address (though there were some things in it from which he might be disposed perhaps to dissent), he had listened with very great pleasure. He would say of Mr. Groves that, though he had never seen him until that evening, he had often read his papers with very great pleasure. He well remembered, twelve years ago, when Mr. Charles Harvey, of London, a friend of his, mentioned that he knew a gentleman of the name of Groves, who was a most extraordinary man, and who was working at all times in the laboratory, and he really did not wonder at those expressions of Mr. Harvey, when he saw the papers of Mr. Groves. He had therefore great pleasure in proposing the toast of "Prosperity to the British Pharmaceutical Conference," coupling with it the name of T. B. Groves, Esq., the president.

The toast was drunk with great enthusiasm.

The President (who in rising was received with loud and long-continued applause) said: Gentlemen, I am afraid your hearty applause has taken all the conceit out of me. A very wise man has observed that some men are called to honour, some achieve honour, and some have honour thrust upon them. I am quite sure that I have honour thrust upon me. When my name was proposed as president for this year, I can assure you I was never more astonished. I was astounded in fact. What induced my friends to put me in this position to be president here in London, when I live so far away in the country, I cannot imagine. I am rather inclined to think that this fact has something to do with it, that my friend the President of the British Pharmaceutical Society is named Hills, and I am named Groves, and as hills and groves are frequently found together, I suppose that may have given rise to the suggestion that I should occupy the chair. (Loud laughter.) I will not deny that I have always been a staunch supporter of the Conference. I was present at its birth in Newcastle, and have occupied a post on its management ever since, and if it is a reward to me, I will not accept it so much for what I have done, as to encourage the younger members in their future career. Let them work, whether their results be good or bad; in the end they must succeed. I will not say that I have done much in the way of success, but, nevertheless, I have worked, and I hoped. There are many in this room to-night who will aspire to the honour of being president, and who will go the right way to obtain it if they work. The Conference, as you all know, was never to be antagonistic to the British Pharmaceutical Society; on the contrary, it was formed with the view, I might say, of being a roving member of that Society. The Society, holding all its meetings in London, had often in the country been regarded more as a London institution; but the Conference has carried the reputation of the Society all over the kingdom, and the result has been of great profit to both of us. I hope, gentlemen, you will go on for the next ten years' as comfortably and successfully and prosperously as you have in the past. We have achieved much, and I hope in the future we shall achieve still more. There never has been any question about the success of our social gatherings, and I think this one beats all. I have often had misgivings as to the success of our Conference from a scientific point of view, but I think this year we may also congratulate ourselves on its success in that respect, and I view the future of our Conference with very great hopes indeed. As your president I am very grateful for the honour you have done me. You certainly have valued my efforts far too highly. I hope we shall go on prospering, and that the young men in this room will aspire to fill my place. (Loud cheers.)

Professor Attfield, in proposing the toast of "The Visitors," and coupling with it the name of Dr. Frazer, of Dublin, said that from year to year they alternately played the part of hosts and guests, of visitors and visited; and very pleasing these alternate relations were. The Conference was peculiarly fortunate at its meetings every year in having visitors from all quarters of the globe. They had had gentlemen from nearly all the States of America, from the South of Africa, from nearly every part of Europe, and from every part of the British dominions. He would ask the visitors when they went home to tell their friends that the British Pharmaceutical Conference was single in its aim, which was that of the prosecution of original research. Twelve years ago, before it came into existence, original research in this country was prosecuted and was encouraged by the Pharmaceutical Society of Great Britain, by means of its evening meetings, and its Journal, which, at that time was published monthly. But now the Journal was weekly, and it therefore took away fifty-two original papers, yet, in spite of that, the Conference presented to the world a clear addition of some thirty to forty original researches. He would ask them to tell their friends, no matter what language they spoke, that those in England, whether as members of the British Pharmaceutical Society, or as Members of the British Pharmaceutical Conference, at all events, 2300 gentlemen read the researches made in Germany, in France, in Italy, and in all quarters of the civilized globe, as they were presented in a collected form in the Year-book of Pharmacy. (Cheers.)

Dr. Frazer, of Dublin, thanked the meeting most sincerely, in the name of the visitors, for the kind, harmonious, and cordial reception they had received, and he must say he had never met with more harmony in any meeting than he had met there. He did most sincerely wish to see an extension across the water of the bounds of both Institutions, and if that were the case, he was sure they would receive a cordial Irish welcome. For himself, he could speak in nothing but the sincerest terms of gratitude for the kindness he had received from every one with whom he had come into contact, and he did hope, not only for the sake of science, but for the sake of that common brotherhood in science which had always existed, that the Irish Channel would not be the boundary henceforth, either of the British Pharmaceutical Conference, or of the British Pharmaceutical Society. (Applause.)

Mr. Giles apologized for venturing to propose a toast but he was sure every one from the country, assembled as they were, enjoying the pleasures of a most agreeable repast, would feel they were indebted to their friends in London for organizing and providing that most elegant and successful entertainment. He thought they ought not to part without expressing their congratulations at its success and their sense of the obligation they felt. He would, therefore, take the liberty of proposing the health of the London members of the Conference, coupling with it the name of Mr. Carteighe.

Mr. Carteighe (who was greeted with loud cheers) returned thanks, observing that it was too early for himself and his friends to be thanked, while there yet remained so much before them, and when, as yet, they had done nothing in the shape of work to justify such an honour. He hoped that the excursion which they proposed taking on Saturday would be a great success, for he felt there was as much utility in an excursion as in the reading of papers or anything else. He did believe in the necessity of bringing men of kindred thoughts in contact. Their previous excursions had been of immense good. The value of these meetings was greatly enhanced by the opportunity they afforded of coming in contact with men who had the same objects, and who were thus able to assist in the advancement of art and science by associating personally one with another, and talking over their different views. And while he held that excursions were very pleasurable, he was certain they were also very useful aids, indeed, to pharmacy by that means. (Loud cheers.)

The Pharmaceutical Journal.

SATURDAY, AUGUST 8, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed " Pharm. Journ."*

THE CONFERENCE MEETING.

THE business of the first—and probably for a long time the only—visit of the British Pharmaceutical Conference to London has terminated, and about the time of the publication of these pages many of the members will be preparing to start on the excursion by which the London pharmacists crown their efforts to rivet the bonds of friendship which have been established and strengthened between them and their provincial brethren. Whether for the number and quality of the papers, or the interesting discussions that have followed the reading of them, the meeting of 1874 has been a success, the only drawback having been that the number of members attending it have hardly equalled the hospitable hopes of the Local Committee. The interest with which the proceedings of the Conference are watched by pharmacists outside Great Britain was demonstrated by the presence of Dr. DE VRIJ, from the Hague, Colonel FORNIE and Mr. DOBBIN from the United States, M. ADRIAN and M. GALLOIS from Paris, and Dr. FRAZER and Professor TICHBORNE from Dublin.

The Conversazione was attended by about three hundred and fifty gentlemen, who found ample occupation in examining the chemical, pharmaceutical, microscopical, botanical, and other articles in the exhibition, or in witnessing the demonstration by Mr. DAVIES of Mr. CROOKES'S experiments to show the attractive and repellent properties of light and radiant heat.

On Thursday the General Meeting of the Conference auspiciously commenced by the announcement that five hundred members had been elected by the Executive Committee the previous day. The PRESIDENT'S address, which is printed *in extenso* in another page, was confined to topics of a political nature, and will doubtless obtain the careful consideration of all pharmacists, as containing the opinions of so experienced a leader of their body.

The first paper was read by Dr. DE VRIJ, and described a new method of estimating the pharmaceutic value of cinchona barks, by which not only the alkaloids, but also other active substances, particularly the cinchotannic acid, may be readily determined by the pharmacist himself. At the invitation of the PRESIDENT, Mr. BROUGHTON contributed some important observations as to the state in which the alkaloids exist in the barks (viz., one-fifth quinate, four-fifths tannate), furnishing a key to the principle best applicable for their extraction. He also mentioned the practice in India, of employing the combined alkaloids. In the discussion which followed, Mr. UMNEY, and Mr. GILES criticized severely the liquid extract of cinchona of the B. P., the former recommending percolation with proof spirit (product to contain 1 in 1).

PROF. FLÜCKIGER contributed two papers : in one he reported that he had determined the deposit from essential oil of nutmegs, known generally as myristicon, to be really myristic acid; in the other he described the chemistry of elemi.

Dr. DE VRIJ then gave the result of his experience of the anthelmintic virtues of pomegranate root-bark.

It was appropriate that it should have fallen to the lot of the PRESIDENT to present the first of the reports of investigations, towards the expenses of which grants have been made by the Conference from the funds entrusted to it by Mr. THOMAS HYDE HILLS. The subject was a continuation of his researches upon the aconite bases. Mr. GROVES having prepared specimens of the alkaloids, the determination of their chemical constitution was undertaken by Dr. C. R. A. WRIGHT, who arrived at the conclusion that aconitine, pseudaconitine, and another body which Mr. GROVES'S at first thought to be Mr. BROUGHTON'S atisine, are polymerides. Mr. BROUGHTON has, however, since stated that he is certain that the body to which he has given the name of atisine is not of the same centesimal composition as aconitine, so that Mr. GROVE'S alkaloid may prove to be a fresh discovery.

This report was followed by another that had been entrusted to Mr. A. W. GERRARD, on the official plasters, which was an able criticism of the present formula, and contained several suggestions for their improvement ; Mr. GERRARD was also able to contribute to the information of many present by a dexterous demonstration of the art of plaster spreading.

The use of oleic acid in pharmacy was the subject of a valuable paper by Professor TICHBORNE, in which he advocated the substitution of oleic acid for soap in the preparation of the liniments of the Pharmacopœia, and he illustrated his argument by the preparation of Linimentum Ammoniæ, Lin. Potassii Iodidi c. Sapone, Lin. Saponis, and Lin. Terebinthinæ. Objection was raised as to the difficulty of obtaining a sufficiently pure oleic acid, but Mr. TICHBORNE said that it could be obtained with facility, and even if this be not at present the case, there can be little doubt that a supply would follow the demand.

Mr. STODDART then described a modification of LIEBIG'S process for the estimation of phosphoric acid, and afterwards practically exhibited the method of estimating the quality of milk recently suggested by Mr. HORSLEY, of Cheltenham, which consists in treating the milk in long tubes with ether and water, by which means the casein, salts and butter fat are separated in distinct layers. This process he also proposed to extend to the analysis of butter, showing by experiment, that lard, for instance, in the cold, was not wholly soluble in ether, and therefore separated from the normal butter fat. The perfection of this test was, however, questioned, especially by Dr. Redwood, who, admitting that the test might detect a clumsy adulteration with lard or suet, was of opinion that there was no proof that it would expose a skilful admixture of fats more nearly approaching butter in its physical character.

This concluded the business of the first day's meeting. In the evening the members dined together at the Cannon Street Hotel; but for an account of the proceedings there we must refer our readers to p. 101.

On Friday the first paper read was a "Note on Cortex Rhamni Frangulæ," by Mr. H. C. Baildon. In continuation of his own and other previous remarks on this bark, Mr. Baildon urges the importance of selecting *good samples, i.e.*, corresponding to such a description as that of the German Pharmacopœia, and for administration he recommends concentrated decoction (or liquid extract); also a concentrated tincture. The paper led to the expression of a considerable amount of personal testimony to the value of black alder bark as an aperient.

Mr. Louis Siebold mentioned the important fact that the concentrated Liq. Ammon. Acetatis exerts a very evident solvent power on any lead which may be present in the glass vessel containing it, and suggested the propriety of keeping such solution in bottles of Bohemian glass.

In a "Note on Scammony," by Mr. T. Greenish, the use of the microscope was recommended in preference to iodine for examining starch present in scammony, to ascertain whether it was derived accidentally from the scammony root, or from wheat, etc.; the shapes of the granules, and especially of the hilum, being quite characteristic. He has found samples of *lump* virgin scammony invariably free from all starches, whilst every sample *in powder* as uniformly contained scammony starch, and some of them wheat starch in addition, which he attributes to the powder being prepared from the smaller fragments contained in cases of mixed qualities of the drug.

Hydrocyanic acid furnished the topic of not less than four papers. Mr. Barnard S. Proctor recorded the results of some experiments having for their object the discovery of a process for extemporaneous preparations of official acid, and also of a solvent that would diminish the variation in strength dependent on evaporation. Of three solvents,—water, alcohol, and ether,—the latter he found to maintain most nearly its percentage of hydrocyanic acid. Two substitutes for the B. P. hydrocyanic acid were discussed by Mr. W. A. Shenstone, namely, the double cyanide of zinc and potassium proposed by Mr. Towerzey, and the hydrocyanic acid ($\frac{1}{10}$ of B. P. strength), proposed by Dr. Tilden. Experiments by Mr. Shenstone indicate that acid of 0.2 per cent. suffers trifling (if any) loss from either volatilization or decomposition. Mr. Shenstone also found solutions of the double cyanide perfectly stable. He did not, however, approve of its substitution for the B. P. preparation, but he thought the 0·2 per cent. acid would be legitimate. Mr. J. Williams stated that he had found that 20 per cent. of glycerine preserves acid up to the strength of about 5 per cent. This application of glycerine was suggested by the knowledge of its effectiveness in the case of solution of sulphuretted hydrogen.

Mr. L. Siebold had found that a dilute acid 0.1 per cent. ♏xx = ♏j B.P. does not deteriorate much in one month in an 8-oz. bottle in daily use; in unopened bottles it will keep at least three months. He also gave a useful caution to inexperienced chemists when estimating the strength of hydrocyanic acid by Liebig's (nitrate silver) method, that alkalinity to test paper is not necessarily an indication that sufficient alkali has been added.

A contribution to the growing literature respecting the administration of phosphorus was made by Mr. Williams, who prefers for that purpose a solution in alcohol and glycerine, and is of opinion that many of the preparations used and supposed to contain a certain amount of phosphorus, would, if carefully examined, prove to contain it in a more or less oxidized condition.

We must content ourselves with a bare enumeration of the other papers. Mr. Barton expressed a preference for the direct treatment of sarsaparilla root with spirit in larger proportion, in the preparation of of extract. Mr. Haffenden contributed a paper on the confections of pharmacy; Mr. Muir on Potable Water, and its Contamination in House Cisterns, and Mr. Daniels on the Syrups of the Phosphates. Mr. H. Groves, of Florence, sent some interesting information respecting the medicinal plants in use among the Tuscans, and Mr. Hunt added to our knowledge of the pharmacy of the Flowery Land. Professor C. R. A. Wright sent two papers; one on the Essential Oils of Wormwood, Citronella, and Cajeput," and the other a continuation of his researches on the opium alkaloids. Mr. E. Smith suggested a method for the recovery of iodine from the waste in the preparation of iodoform. Mr. W. E. Heathfield sent some notes on the extracts of aconite, belladonna, hemlock, henbane, and colchicum, and Mr. Schacht took the opportunity of explaining the scope of some experiments he is making to ascertain the relative proportions of conia present in the succus and extract of conium. The last paper read was by the President, and described his experience in the preparation of trimethylamine from the skate.

Nothing now remained to be done but to pass the usual votes of thanks, to elect the officers, and decide the place of meeting for the ensuing year. It was resolved to meet at Bristol, and again under the presidency of Mr. T. B. Groves.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, August 5th, 1874.

MR. T. HYDE HILLS, PRESIDENT, IN THE CHAIR.

MR. A. BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Frazer, Hampson, Mackay, Owen, Radley, Rimmington, Robbins, Savage, Schacht, Shaw, Sandford, Stoddart, and Williams.

The minutes of the previous meeting were read and confirmed.

THE PHARMACOPŒIA COMMITTEE.

Mr. ATHERTON inquired if there had been any reply received from the General Medical Council, in regard to the resolution passed at the last Council meeting, on the subject of pharmacists being consulted in the preparation of any future Pharmacopœia.

The SECRETARY read a letter from the Secretary to the Medical Council, simply stating that the resolution had been laid before the Council.

Mr. HAMPSON said the letter was certainly curt, though they could not deny that it was civil. He would simply venture to express a hope that the Parliamentary Committee would be alive to the importance of this question, and that, if any opportunity presented itself, such as any amendment of the Medical Act, it should be taken advantage of to bring the subject under the notice of the Legislature.

THE LATE MR. STANDRING.

The PRESIDENT desired, before the regular business commenced, to express his sense of the loss which the Society had sustained in the death of Mr. Standring, an old member of the Council, and a gentleman who had taken the greatest interest in the proceedings of the Society from its commencement.

Mr. SANDFORD desired to call attention to a matter arising out of the proceedings at the last meeting. It would be remembered that when the Council was discussing the propriety of admitting ladies to the laboratory, he expressed an opinion that Professor Attfield had a little exceeded his province in apportioning them a retiring room. Professor Attfield, instead of applying to the Council to correct anything which he considered conveyed an erroneous impression — which he (Mr. Sandford) thought was the proper course for an official of the Society to take if he felt himself aggrieved—had written a letter to the Journal, repudiating the charge of exceeding his duty, and in so doing he had put a false colour on the matter, by saying—"It was not I who suggested that the housekeeper's cloak-room might serve as a cloak-room for the ladies;" thus making it appear that there was a room available for the purpose, and that the Council were desirous of creating unnecessary difficulties. But the facts were simply these: there was no housekeeper's cloak-room, the room so designated being the bedroom of the porter and his wife; and as he supposed a man had access to his own bedroom at any time, it appeared to him that to allow ladies to make use of it as a cloak-room could scarcely be called providing them with decent accommodation. He thought it only right to make this explanation, lest any erroneous impression should be created.

The PRESIDENT thought it would be satisfactory to all members of the Council that this explanation should have been made.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society.

Aylesbury, William Thomas.
Collier, Henry.
Compton, Arthur.
Cotterell, William Burbidge.
Fairman, George Peters.
Green, Thomas.
Hamond, Joseph.
Hunt, Freeman William.
Kirkby, Robert.
Norman, Joseph Slaughter.
Selkirk, James.
Smith, Thomas James.
Symons, William Henry.
Thirlby, William Arthur.
Thring, Edmund John Henry.
Whyte, Alexander.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society:—

Collier, Henry ....Clapham Common.
Compton, Arthur ....New Beckenham.
Fairman, George Peters ....Sunderland.
Green, Thomas ....Belfast.
Hamond, Joseph ....London.
Hunt, Freeman William ....Aldeburgh.
Kirkby, Robert ....Ambleside.
Symons, William Henry ....Barnstaple.
Thirlby, William Arthur.........Packington.
Thring, Edmund John Henry ..Trowbridge.
Whyte, Alexander ....London.

Chemists and Druggists.

The following registered Chemists and Druggists were elected Members of the Society:—

Davies, Charles.........................London.
Maish, Edward ....Bristol.
Moore, Edward.........................Cheltenham.
Park, William ....Broughty Ferry.
Penney, William S. ....Llandudno.

ASSOCIATES.

The following, having passed the Minor Examination, and being in business, were elected "Associates in Business" of the Society.

Howorth, George Buxton ....Egremont.
Mill, John Brown...................Holsworthy.

The following, having passed the Minor Examination, were elected "Associates" of the Society.

Arnold, Harry Shaw................Cwm-Avon.
Ashmore, George Johnson ......Lindsworth.
Axford, John William ....Coventry.
Baildon, Henry Bellyse ....Edinburgh.
Bailey, John Richard ....Spalding.
Bamfield, John ....Bristol.
Bathe, Frederick James ....Chippenham.
Bray, Ernest Edward ....London.
Brend, Kenneth Benjamin ......Swansea.
Brown, George German ....Dresden.
Catford, Obadiah William ......Chard.
Clifford, Richard Noon ....Melton Mowbray.
Cripps, Ernest Henry ....Devizes.
Dear, Theophilus ....Hornsey Rise.
Duncalf, James Mills ....Congleton.
Dyson, Alfred ....Brighouse.
Endle, Frederick .. ..Barnstaple.
Ewell, Richard Michael ....Sandwich.
Fryer, Arthur..........................Ayston.

Garratt, Arthur ....Guildford.
Garth, John ....Preston.
Gimson, Joseph ....Leicester.
Hall, Peter ....Sunderland.
Halse, Thomas ....Tiverton.
Hands, Henry Joseph ....Chipping Campden.
Hayhoe, William ....Diss.
Hillier, Henry ....Newport.
Hitchcock, James ....Whittington Moor.
Hogg, Edward Grindle............Ealing.
Holmes, Alfred John ....Preston.
Jenkyn, Thomas, Jun. ....Penzance.
Jones, Jabez Abraham............Birmingham.
Josling, Alfred ....Chelmsford.
Legg, Henry Arthur.................Kingsland.
Lloyd, Rees ....Dowlais.
Long, Theophilus Henry Beavan. Brighton.
Miles, Charles John ....Bristol.
Morson, Thomas Pierre ....London.
Padwick, William Guy ....London.
Passmore, Charles Frederick ...Kilburn.
Price, John........................Swansea.
Pumphrey, John Henry ....Evesham.
Purvis, Thomas Alexander ......Gosport.
Read, John Henry..................London.
Russel, Thomas Gregory ....Cambridge.
Solomon, Charles Edwin ....Penryn.
Sneath, Thomas Dixon............Newark.
Stephenson, Robert ....Bradford.
Street, John Westrope............Melton Mowbray.
Tigar, Hardwick Brigham ......Beverley.
Tomlinson, Eldred Edward......Whitehaven.
Townend, Thomas Francis ..... Durham.
Wedge, George Deller............Alresford.
Wilks, Robert ....Skipton.
Woolston, Thomas Henry ......Faversham.
Wright, Robert........................South Shields.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination, were elected apprentices or students of the Society :—

Ackerman, Henry.................Chipping Sodbury.
Allen, John ....Manchester.
Beech, Joseph, Jun.................Birmingham.
Bilson, Frederic Eastall ....Newark.
Blaymire, Thomas Croskell.......Kendal.
Bovill, Edmund........................Whitby.
Buchan, Jno. Greig ....London.
Burman, George Alfred ....Towcester.
Caven, William Alexander ....Dalbeattie.
Clough, Alfred ....Northwich.
Crompton, Alfred, Jun. ....Bury.
Crompton, Henry ....Bury.
Culley, Charles ....Leicester.
Davies, Hugh ....Liverpool.
Eccles, Robert Burton ....Brigg.
Fazan, Charles Herbert ....Colchester.
Green, George ....Horncastle.
Harrison, Frederick ....Brighton.
Hutton, Harry .... Warwick.
Johnson, Walter Edmund ......London.
Kendrick, Alfred ....Limehouse.
McAlley, Robert, Jun...............Edinburgh.
Porteous, Arthur Alexander ...Kirkwall.
Purves, Peter........................Edinburgh.
Potts, Walter ....Oldham.
Richards, Philip ....Bury St Edmunds.
Roberts, George William.........Manchester.
Rogers, Charles........................Nottingham.
Rose, Charles........................Birmingham.
Scott, Jeffers Wilson ....Douglas.
Shaw, John William ....Guisborough.
Smith, Andrew Lees ....Selkirk.
Stewart, Donald ....Forres.
Townend, Thomas Francis ......Durham.
Varney, Henry George ....Oxford.
Walker, James ....Auchmull.
Ward, Thomas William ....Towcester.
White, Charles ....Southborough.

The name of John Newton Watts, of 217, Edgware Road, was restored to the Register of Chemists and Druggists.

Several individuals who had neglected to pay their subscriptions in proper time, were ordered to be restored to their former status on payment of the subscription for the current year, and a fine equal to half the amount.

FINANCE.

The report of this Committee, recommending the payment of sundry accounts, was read and confirmed.

BENEVOLENT FUND.

The report and recommendations of this Committee were received and adopted.

A grant of £10 was made to a former member, at Brighton, in distressed circumstances.

A grant of £10 to the widow of a pharmaceutical chemist in Scotland.

A grant of £15 to a chemist, at Sheffield, in distress from ill-health.

A grant of £10 to the daughter of a deceased chemist and druggist.

LIBRARY, MUSEUM, AND LABORATORY COMMITTEE.

The minutes of this Committee were read. They stated that, according to the report of the librarian, the average attendance in the library had been, during the day, 21·875; evening, 5·6. Circulation of books, in town, 142; country, 34. The average attendance in the museum had been, daily 20; evening, 5. Professor Attfield had reported that there had been 90 entries in the laboratory since the commencement of the session. Number of pupils working at the date of report, 35.

The following books were recommended to be purchased for the library :—

Virgil.
French Grammar.
German Grammar.
Thomson's Conspectus, by Birkett.
Bloxam's Laboratory Teaching.

The Committee also recommended that the library be closed in the evening during the recess.

The report and recommendations of the Committee were received and adopted, and the Museum was ordered to be closed during August and September.

HOUSE.

The report of the House-Committee was received and adopted.

PARLIAMENTARY.

This Committee reported that they had held meetings to consider the Apothecaries' Licences Bill, and that two of their members had given evidence before the Select Committee of the House of Commons. The Juries Bill had been withdrawn.

The SECRETARY stated that the minutes of the evidence taken before the Select Committee on the Apothecaries' Licences Bill had been published that morning. The report had been issued before, and it had been published in the Journal.

The report was adopted, and it was resolved that each Member of the Council be supplied with a copy of the minutes of evidence above referred to.

GENERAL PURPOSES.

The only matters which had come before this Committee, were the reports of the Professors as to the sessional prizes, etc. Professor Redwood reported that he considered the new arrangement with respect to the lectures satisfactory in every respect, except in regard to the remuneration afforded to the Professors, and he believed his colleague, Professor Bentley, agreed with him. There had been 41 entries for the first course, and 40 for the second. At the end of the season there had been two examinations, one for students who had attended the whole course of ten months, who were eligible to compete for the silver medal and certificates; and the other for those who, having only attended one course of lectures, were only eligible to compete for the bronze medal. For the former examination there had been 13 competitors, for the latter 5.

Professor Bentley reported very favourably as to the regular and punctual attendance and good conduct generally of the students attending his classes; and stated that he had every reason to be gratified, except as to the numbers.

Professor Attfield reported that there had been 23 entries in his class during the ten months, the average period of work being 3¾ months. There had been 9 competitors at the prize examination, of whom the most successful had attained the highest number of marks possible.

Professor Bentley also reported that there had been only one collection of plants sent in, to which he recommended that a bronze medal be awarded. It consisted of 370 specimens.

Mr. STODDART said he thought Professor Bentley was rather hard on the competitors for the Herbarium; he did not seem to think that 300 was a great number of plants, but the fact was, for a young man who was employed all day to collect so many, and to change them every day, and properly prepare them, was no slight task. He knew of one case a short time ago when the silver medal was given to a gentleman who had his whole time at his disposal, and who had *carte blanche* to go all over the kingdom collecting specimens; the consequence was, that many young men in business felt it was totally useless to attempt competing under such circumstances.

Mr. SAVAGE fully endorsed Mr. Stoddart's observations. He thought there was too high a standard set up in this respect, and that it would have to be lowered. One of his own young men was very anxious to enter for this prize, and put his name down, but after he had been at it a month or two, he found it absorbed the whole of his time to the neglect of other studies, so that it was very questionable whether he would carry out his design.

Mr. SCHACHT said the remarks which had been made were very appropriate, but he had no doubt, on a conference with Professor Bentley, matters might be arranged more satisfactorily. He wished, however, to make a remark on the general question of the professors' reports, which he had not listened to with perfect satisfaction. He was not prepared to suggest any course of action at present, but he must say he was not satisfied with the result of the working of the lecture portion of the school. They had been often told, and very properly, that the institution was not a local one; that it was designed for pharmacists all over England; but viewing it in that light, he was a little disappointed to find that, so far as one could make out, there had been only ten competitors for the prizes offered in Botany, and thirteen or fifteen in the other subjects, while there were about forty students attending the different courses of instruction. Many local associations could present almost as good results as that. He was not quite sure whether the working of the new scheme was yet fully developed or not; perhaps it was too soon to judge, but he did not like these reports to pass without a single word of comment, and he thought it would be well if one of the Committees could make something like a better analysis of the new scheme, and of the comparative results obtained under it, than had at present been put forward. At present he did not quite understand on what grounds Professor Redwood commenced his report in such satisfactory terms, for though he was sorry to hear that the classes had not been so remunerative to the professors as they could wish, still another result not less important was that the attendance had not been so great as was anticipated. He could not but compare the number of students with the number presenting themselves for examination, which was 303 during last month. That represented a large number of persons anxious to obtain recognition as pharmacists, and it seemed rather a meagre result that only forty of them could be found desirous to obtain the instruction there offered, and to compete for the high and distinguished rewards offered by the Society to successful students.

Mr. MACKAY said that, like Mr. Schacht, he was rather disappointed, not altogether with the results of the attendance, but that they had not a proper and fair analysis of how the various classes had worked since the recent change in the arrangements. Professor Attfield seemed to think that, as far as he was concerned, no material change had taken place, but in the other classes there had been a slight increase, for although Mr. Schacht spoke of the attendance being 40, as far as he could gather from Professor Bentley, there had been something like 70 attending during the session, whilst in the previous year he believed the number was 60. The total number of attendances on Professor Redwood's lectures also was 81, but they had no comparative statement to show the numbers attending in the previous year. He thought, however, some such statement should be prepared, though whatever the result of the analysis might be, it would be too soon to judge yet of the real results.

Mr. ATHERTON said he had been told, on very good authority, that the two courses of lectures on chemistry and pharmacy were almost word for word identical, and if that were the case one could hardly be surprised at the results not being satisfactory.

Mr. MACKAY said it could hardly be satisfactory unless the courses of lectures on chemistry were so dissimilar that a student going through the whole course, from October to July, could derive benefit from the whole of the lectures.

Mr. WILLIAMS reminded Mr. Atherton that it was understood the two courses of lectures were to be identical—the same information was to be gone over twice.

Mr. SCHACHT said it was distinctly asserted, he believed, that the illustrations were to be fresh, though the general principles of the course must be gone over again.

Mr. HAMPSON said he did not think it desirable, at present, to introduce any special inquiry into the working of the system which had scarcely had time to get into operation.

The PRESIDENT said he understood it was stated at the Committee, by Professor Bentley, that the session had been very unremunerative to him—that he had received £75 less than last year.

Mr. WILLIAMS said it was £220 less that Professor Bentley had received.

Mr. BETTY thought, if that were so, they were bound at once to institute an inquiry. They could not blink the fact that it was commonly reported that the two courses of lectures were precisely the same, and that this was causing great dissatisfaction with the new system. He thought they had better appoint a Committee to look into the matter, and see how it was acting, and how it was likely to operate in the ensuing year. If they allowed things to go on as at present with this sort of inuendo hanging over, it would be very likely to damage the school irretrievably.

The PRESIDENT said he had inquired of Professor Bentley if it were really the case that he was out of pocket by the new arrangements, and he informed him it was so. He had then asked Professor Redwood, who told him he was £100 worse off by the change.

Mr. SCHACHT having asked what was the amount of fees received by the Professors, Mr. Mackay said that was one of the points which they required further information upon. They did not know how many fees had been received, or what were the results.

Mr. Betty said he would move that Professors Redwood and Bentley be invited to meet a sub-Committee to confer with them on the working of the new regulations lately made by the Council.

In reply to Mr. Schacht,

The Secretary said there were five candidates for the Bell Scholarships.

Mr. Sandford thought there had been a little misapprehension as to the two courses of lectures. He read an extract from the new regulations, stating that the instruction given in the first five months was to be *repeated* in the second course, though it also stated that "some of the facts will not be the same in each of the courses."

Mr. Hampson had heard it reported that not only were the lectures identical in the second courses, but also the illustrations and experiments; so that any students who had taken notes of the first course found the second absolutely useless. But if the whole subject was going to be inquired into, he hoped a notice of motion would be given, so that it might be fully considered.

Mr. Shaw said his recollection of what took place at the interview with the Professors preparatory to the promulgation of the new scheme was that they stated that the course of instruction they had been accustomed to give in ten months might be compressed into five, so that the lectures in the two courses would be substantially identical.

Mr. Williams said he had opposed as strongly as he could this division into two courses, on the ground that they would be practically identical. At the same time he understood that the Professors had promised that they would, to some extent, vary the experiments. The theory was that what was formerly taught in ten months could be taught in five; but for his own part he did not think ten months any too long a time in which to learn chemistry and pharmacy.

Mr. Frazer said it would be no doubt very easy for the Professors to give two distinct courses of lectures, especially as they had been accustomed to spread their course of instruction over ten months.

Mr. Williams remarked that the Professors desired to give a complete course of instruction in five months, and expressed their opinion that they could satisfactorily do so.

Mr. Frazer said there was, evidently, some ground for inquiry, since it was stated that the remuneration of the Professors, which had never been excessive, had considerably fallen off, but as they were at present in a transition state, with a new system of examination about to be introduced, he did not think they were yet in a position to look narrowly into the matter, and recommended waiting for another year.

Mr. Mackay said he had as yet heard nothing to change his opinion, that a Committee ought to make some inquiry into this matter.

Mr. Baynes could confirm what had been said by Mr. Shaw, that the ten months' course had been compressed practically into five. He thought their experience was not sufficient as yet to enable them to pronounce a positive opinion as to the failure or success of the scheme, though it was not too soon to make inquiries.

Mr. Schacht said he would second the motion proposed by Mr. Betty.

Mr. Williams asked what it was that was proposed to be done? Was the Committee to be authorized to recommend that the whole system should again be altered and changed?

Mr. Mackay apprehended the arrangements would not be disturbed for another year, whatever the alterations might be.

Mr. Schacht said he had not heard any one say he considered the condition of the school satisfactory on the whole, and therefore he thought there was ground for inquiry.

Mr. Hampson hoped the Committee would go thoroughly into the whole matter. The school was not as successful as could be wished, and he hoped the Committee would, if appointed, go thoroughly into the matter, and inquire into the causes of the failure.

After some further conversation, the following resolution was carried unanimously:—

"That a Committee, consisting of Messrs. Hampson, Greenish, Schacht, Betty, and Sandford, be appointed, to inquire into, and report on, the educational arrangements of the School at Bloomsbury Square."

Prize Awards.

The following awards were made on the reports and recommendations of the Professors, and of the Board of Examiners:—

Jacob Bell Memorial Scholarships.

William Henry Vernon.

George Green.

Pereira Medal.

Arthur Pearson Luff.

Prize of Books.

Arthur Pearson Luff.

Chemistry and Pharmacy.

[Ten months' course.]

Silver Medal......................William Henry Symons.

Certificates of Honour......... William Ayton Gostling. / Harry Alma Thomas. / Alexander Whyte.

Certificates of Merit .... Arthur Pearson Luff. / Henry George Greenish. / William Arthur Thirlby.

[Five months' course.]

Bronze Medal ....William Henry Symons.

Botany and Materia Medica.

[Ten months' course.]

Silver Medal ....Arthur Pearson Luff.

Certificates of Honour .... William Arthur Thirlby. / Alexander Whyte.

Certificates of Merit .... William Ayton Gostling. / William Henry Symons. / Henry George Stacey.

[Five months' course.]

Bronze Medal ....Alexander Whyte.

Practical Chemistry.

Silver Medal ....Arthur Pearson Luff.

Bronze Medals .... William Ayton Gostling. / Allan Fox Sainsbury.

Certificates of Merit .... Arthur Joseph Carter. / William Arthur Thirlby.

Botanical Prize.

Bronze Medal......................Thomas Wm. Nettleship

Reports on the Examinations of the Pharmaceutical Society held in London during the Year 1873.

The Secretary read the following reports, which had been sent by the Privy Council for the information of the Society:—

During the year 1873, the Board of Examiners of the Pharmaceutical Society held four meetings for the Preliminary examination of candidates in Latin, English, and arithmetic, and thirty-six meetings for the Technical examinations.

At the *Preliminary* examinations, 1292 candidates presented themselves, of whom 670 passed, and 622, or about 48 per cent., were rejected.

There is a larger proportion of failures than I have had to report in any previous year, and the increase, I have no doubt, is to be attributed in great measure to the change in the regulations with respect to marks, to which I referred in my report for the year 1872. I there stated, with respect to the Preliminary examination, that it had been found that more than usual competency in English and arithmetic had enabled candidates to pass the examination, who had only obtained one-fourth of the number of marks in Latin. Under the regulations then in force, the number of marks allotted to each of the three subjects comprised in the examination being 100, and the passing number for the whole examination being 150, whilst the minimum passing number in each subject was only 25, it followed that a candidate who should have obtained 125 marks in English and arithmetic would pass the examination, although he should be so weak in Latin as only to obtain 25 marks, or one-fourth of the number allotted to that subject.

The same objection applied to the regulations with respect to marks at the technical examinations, in which also a candidate who had obtained only one-fourth of the marks in one or more of the subjects might nevertheless pass the examination if he had obtained the requisite number of marks on the aggregate of all the subjects.

With the view of ensuring a more equal degree of competency in all the subjects comprised in the several examinations, it was last year resolved by the Board of Examiners to raise the proportion of marks necessary for passing in each subject from one-fourth to four-tenths of the total number of marks allotted to that subject separately, without making any change in the number of marks required for passing the examination as a whole.

This regulation has been in force throughout the year 1873, and has undoubtedly tended in the Preliminary examination to secure a higher degree of competency in Latin, whilst it has probably also led to the rejection of some candidates who, under the previous system of adjudication, would, notwithstanding their weakness in Latin, have passed the examination as a whole by the means of their strength in other subjects.

Another cause of the unusually large proportion of rejections during the past year has probably been the premature examination of candidates anxious to obtain a qualification before October 1874, when new regulations will come into force, with respect to the examination for the Minor qualification.

As regards the rejected candidates, it is satisfactory to know that for the most part they present themselves again at a subsequent period, and that a considerable proportion of them eventually pass the examinations, some of them even with credit.

At the Technical examination, 73 candidates presented themselves to obtain the *Major* qualification, of whom 49 passed and 24, or nearly 33 per cent., were rejected.

This proportion of failures is one-fourth smaller than it was in 1872, although still somewhat larger than in previous years. The large increase in the proportion of failures which took place in 1872 was coincident with the substitution of a practical examination in chemical analysis, in place of the written examination previously given. Since then it has become well understood that this more practical test of competency is now required, and the candidates, having prepared themselves for it, the proportion of failures has fallen again from 43 per cent. in 1872, to 33 per cent. in 1873.

I have been present on several occasions at this practical examination, and am able to state that it is searching and perfectly fair, and that many of the candidates go to work in a skilful and thoroughly business-like manner. The matters submitted to them for analysis are such salts as sulphate of quinia, acetate of morphia, sulphate of strychnia, oxalate of potash, and the like. Each article to be analysed is distinguished by a number, and candidates are required to determine the base and the acid, and to explain in writing the processes they have made use of in their analysis. Each candidate is placed by himself at a counter, upon which are arranged all the articles required for testing, and he is expected to analyse at least three substances during the three hours allotted for this part of the examination. In order to prevent the possibility of collusion between the candidates, a large number of substances are prepared beforehand, and no two of the candidates have any of the same substances submitted to them for analysis.

For the *Minor* qualification there have been 745 candidates, of whom 410 passed, and 335, or nearly 45 per cent., failed.

This proportion of failures does not differ materially from that of 1872, but it has been considerably higher in both these years than it was before. It must, however, be borne in mind that the same causes to which I have already adverted as increasing the proportion of failures in the Preliminary examination, have been in operation also with respect to the Minor examination, viz., the raising of the passing number of marks for each separate subject of examination, and the desire of candidates to obtain a qualification before October, 1874. The supposition that this latter cause has led many candidates to present themselves prematurely seems borne out by the fact that the number of candidates for the Minor examination has risen, during the year 1873, to a total of 273 above that of 1872; a rate of increase greatly in excess of that which has obtained in previous years.

Only 95 candidates have presented themselves for the *Modified* examination, of whom 60 passed, and 35, or nearly 37 per cent., were rejected.

I am of opinion that the several alterations adopted by the Board of Examiners during the last two or three years, viz., those of rendering the Major examination more practical, of raising the passing number of marks in each individual subject of examination, and of requiring rejected candidates who present themselves for re-examination to pass in all the subjects, even though they may have previously obtained the passing number of marks in some of the subjects—have worked satisfactorily as regards the candidates themselves, and advantageously for the public service.

As I explained in my last report, amended regulations providing for the more practical examination of candidates for the Minor qualification will come into operation in October next. When these shall be fully enforced, the examinations of the Pharmaceutical Society will have been made as complete as appears for the present to be attainable; and I am of opinion that it was only just that the regulations should not have been made too strict in the first instance, and that the Board of Examiners have shown good judgment and discretion in the important but gradual improvements which they have effected in the scope and conduct of the examinations.

(Signed) E. Headlam Greenhow.

14*a*, *Manchester Square*,
March 28*th*, 1874.

Report of Government Visitors.

Dr. Maclagan's Report on Examinations by the North British Branch of the Pharmaceutical Society of Great Britain.

Since the date of my report of 27th March, 1873, I have been present during the greater part of the sederunt, on the following days of examination in Edinburgh:—

1873, 16th April.
„ 25th and 26th June.
„ 14th, 15th, and 16th October.
1874, 13th and 15th January.

The general conclusion to which my supervision of the examinations has led me is, that the examiners continue to discharge their duties satisfactorily, showing their full qualification for the office, and maintaining a due regard at once to the interests of the public and of the candidates. The amount of rejections at all the examinations is great, but is not, in my opinion, due to unnecessary severity on the part of the examiners. It seems not improbable that the knowledge that hereafter all candidates will require to be of the age of 21 before receiving their diplomas, has led a number of young men, without adequate preparation, to try to pass the examinations before the new regulation comes into operation.

On the several examinations I have to offer the following remarks:—

Preliminary Examinations.—At these examinations the total number of candidates during the past year was 148, of whom 87 satisfied the examiners, and 61 failed. The proportion of failures—41·2 per cent., does not differ much from that of last year—44·3 per cent. I repeat the opinion expressed in my last report that these examinations are not too severe; on the contrary, I hold that if any change, which, however, I do not in the meantime advise—were to be made in them, it ought to be in the way of exacting more rather than less. Last year the average number of marks obtained by successful candidates seemed to be so very nearly equal in all the three subjects required (Latin, arithmetic, and English) that there was no one of them that could be pointed to as constituting a leading deficiency in candidates. The result of the year now under consideration is somewhat different. The most numerous failures have been in the subject of arithmetic, and in all candidates, successful or not, the marks obtained in this department have been below those obtained in the other two. Taking the Preliminary examination of 7th July as a fair average sample, the total marks obtained by all the candidates, whether they passed or not, were:—

Latin	69·5 per cent.
English	64·6 „
Arithmetic	38·5 „

I do not venture to generalize from these results, which may possibly be exceptional, but I record them as a contribution to the statistics of these Preliminary examinations, from which, when we have more data, we may be able to draw practical conclusions. It is enough in the meantime to call attention to the present deficiency in arithmetic, with a view to urging its importance upon future candidates. Not merely for the cultivation of the science of chemistry, but for the ordinary work of the dispenser, accuracy and promptitude in arithmetic are essential.

Technical Examinations.—At these examinations 152 candidates presented themselves, and the results were as follow:—

	Passed.	Failed.	Total.	Percentage of Rejections.
Major . . .	6	4	10	40
Minor . . .	65	51	116	43·96
Modified . .	19	7	26	26·92

It is hardly necessary to make any remarks upon the Modified examinations, because the class of persons who present themselves for them is limited in number, and will soon become exhausted. These Modified examinations are upon all hands admitted to be unsatisfactory. The Major and Minor examinations, on the other hand, are, to my mind, satisfactory. They have, in some respects, been improved since I had the opportunity of observing them, but they are, I think, capable of further improvement. In the spring of 1873, it appeared to me that the examinations in Botany were so far imperfect that the candidates had presented to them only herbarium specimens of plants, which enabled them to do little more than recognize species, and did not afford any opportunity of ascertaining the candidate's knowledge of vegetable organography and general classification. I have been, through the kindness of Professor Balfour, enabled since then to obtain for the examiners regular supplies of fresh plants from the Royal Botanic Gardens, and the result has been that in the examinations in June and ever since, there has been a marked improvement in the botanical examinations, which are now to be regarded as very satisfactory. Another improvement has, at my suggestion, been introduced into the examinations, to which I attach some importance—I mean, the use of the microscope. It is hardly possible thoroughly to test a candidate's knowledge of botany without an appeal to the microscope, but this is still more important in reference to adulterations of drugs, many of which are detectable by its use, where chemistry totally fails to discover such frauds. At the October examination, therefore, the microscope was brought into use, and on this occasion I conducted this part of the examination myself, taking occasion to inform candidates that, as no notice had been given that they would be tested by the use of the microscope, it was desired in the meantime only to ascertain how far pharmaceutical students were acquainted with its use, and that their performances were not to count either for or against them as regarded the result of their examinations. I had an opportunity in this way of trying 1 Major and 16 Minor candidates. The candidate for the Major diploma was found fairish, but by no means so good as many of the Minors. Of these, 5 had worked more or less with the microscope, and all of them made good appearances—two in particular, one of whom had a microscope of his own, the other being the brother of a student of medicine, who is well known to me as a good microscopist. The 11 other Minors had had little or no opportunity of using the microscope—some had indeed never looked through a microscope at all.

The average result may be said to have been satisfactory, some of them readily recognizing vegetable structures from the drawings in their text-books. One candidate only could make absolutely nothing of it. It thus appears that there would be no hardship in insisting upon a knowledge of microscopic appearances as part of the qualifications of a pharmaceutist of either grade. The very fact that microscopic appearances are appealed to in many instances in the Pharmacopœia, is, I think, sufficient justification of this.

As regards the examination in Chemistry, there is a call for some improvement, which is in course of being responded to. I am still disposed to regard as highly satisfactory the written papers on this subject required from Major candidates, as bringing out thoroughly their knowledge of chemical theory, and I am not disposed to recommend the abolition of this.

There has hitherto been no opportunity in Edinburgh of testing candidates practically in chemical work, as is done very satisfactorily in the examinations in London.

Arrangements are now, however, being made by the North British Branch, to acquire new rooms, one of which is to be a laboratory, in which the candidates will be made to perform actual analyses. These practical chemical trials have, even in London, hitherto been restricted to Major candidates; I am, however, very decidedly of opinion that in the case of Minors, an actual demonstration of some of the simpler chemical reactions would not only be found a more satisfactory test than the mere asking of questions regarding them, but would be more acceptable to the candidates themselves. It appears to me, therefore, that this should be done at once, in the case of Minors, whilst, as in London, all Majors should be required to make one or two more elaborate analyses.

Hitherto in Edinburgh, from the want of a proper laboratory, this has been restricted to one or two processes of volumetric analysis.

In the month of March, 1874, I went, at the request of

Mr. Simon, to London, to be present at the pharmaceutical examinations there. Two members of the Edinburgh Board of Examiners, Messrs. Tait and Gilmour, accompanied me. The immediate object of our visit was, by personal intercourse, to come to a definite conclusion as to certain differences of opinion which had existed between the London and Edinburgh Boards, as to the rigid adherence to the value of answers in determining the passing or rejection of candidates who had done well in some of the subjects of examination, but had in one of them made appearances not quite up to the required standard. In addition to the opportunity of actually witnessing the examinations in London, we had the advantage of full and free discussion of the whole subject of the examinations between the members of the London and Edinburgh Boards. To go into the details of this would add unnecessarily to the length of this report. It is enough to say that to me, and I think I may say to the gentlemen who were with me, this conference was very satisfactory, and that the result will be a more complete uniformity in the decisions of the two Boards, so that no candidate will have any inducement to suppose that he will be more likely, if not adequately informed, to pass in one part of the kingdom than another. Though it does not fall within my duty, I may, I hope, be permitted to record my satisfaction with the style and character of the examinations in Bloomsbury Square.

(Signed) DOUGLAS MACLAGAN.

Mr. HAMPSON, with reference to the use of the microscope by Dr. Maclagan, at Edinburgh, thought that that gentleman had rather stepped out of his proper position in attempting to examine candidates or test the quality of their knowledge, and he thought it was to be regretted that young men who only had a limited time given them for answering the questions should have any quantity of that time taken up in testing their knowledge of the microscope.

Mr. MACKAY said it was an idea of Professor Maclagan that chemists should use the microscope for the purpose of their avocations, and he must distinctly state that, before Prof. Maclagan asked any candidate to go to the microscope, he cautioned him that whether he knew anything about it or not it would not in any way add to or detract from his position in the examination. He was quite certain that those who went to it, were rather pleased than otherwise.

Mr. RIMMINGTON said he understood that the microscope had been introduced into the examinations in Bloomsbury Square.

The VICE-PRESIDENT said one had been introduced simply as an experiment, as had been explained had been done at Edinburgh; but it formed no part of the examination.

Mr. HAMPSON thought it was not advisable to take up any young man's time with a matter which did not form part of the subject of the examination. He must also protest against the action of the representative of the Privy Council, in introducing the microscope, and testing the candidate's knowledge of it in the examination-room.

Mr. WILLIAMS thought it quite right that they should stand up for the great principle that the gentlemen appointed by the Privy Council were not Examiners, and had no right to act as such. The Council appointed the Examiners, and he quite agreed that it was a wrong thing for the Government visitor to attempt even to examine in any matter, although it was not an essential part of the examination.

Mr. MACKAY said that Drs. Maclagan and Greenhow took no part in the examination. They acted as visitors only. The Board did not object to the microscope being shown as described, but he could positively affirm that it occasioned no waste of time, nor did it interfere with the course of the examination.

LADY STUDENTS.

Mr. HAMPSON said he would withdraw for the present the motion of which he had given notice, "That at the ensuing session the laboratory be open to lady students."

The SECRETARY read a letter from four female students, asking permission to attend the course of instruction in the laboratory.

The PRESIDENT said he had had the honour of seeing a deputation on the subject on Saturday, but he had declined giving them any positive answer.

The Secretary was instructed to acknowledge the receipt of the letter.

BRITISH PHARMACEUTICAL CONFERENCE.

The eleventh annual meeting of the British Pharmaceutical Conference was commenced on Wednesday last, August 5th, in the house of the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, London, under the presidency of Mr. T. B. Groves, F.C.S.

Meeting of the Executive Committee.

On that day the proceedings were commenced by a meeting of the Executive Committee. Present—T. B. Groves, President (in the chair); Messrs. Bentley, Stoddart, Brady, Hills, Reynolds, Williams, Schacht, Attfield, Benger, Davies, Carteighe, Clayton, Martindale, Rimmington, and Umney.

The minutes of the previous meeting were read and confirmed.

A letter from the Editor was read, announcing that the MS. of the 'Year Book' would not be ready till the end of September.

Professor Attfield reported as follows respecting Secretarial work done since the previous meeting of the Committee:—

Subscriptions.—At date of last meeting (Jan. 22) 600 subscriptions remained unpaid, although two applications (in July and December) had previously been issued. During the succeeding month (to February 21st) 111 came to hand. On February 21st a third application was sent out for the remaining 489. This brought 139. On May 7th, when distributing the list of subjects for research, application was made for the 350 subscriptions then owing. In response, only 25 were received. The 325 members whose subscriptions were in arrear might thus be classified:—

Owe for more than two years	115
Owe for two years	99
Owe for one year	111
	325

The members who owed for more than two years (115) had been asked for the subscription some sixteen or twenty times, and a special letter had recently been sent to each, stating that, unless the amount was received within ten days, his name would be removed from the list of members. The 99 in arrear for two years would be similarly treated next year, unless they responded to further appeals. There remained a few more than 100 who owed for one year, but 100 might be taken as the maximum number of members withdrawing on account of the increase in the amount of subscription from 5s. to 7s. 6d., made in the year which had just ended (June 30).

On May 7 the list of subjects suggested for research was sent to every member.

In May, also, local secretaries were appointed in all towns where one did not previously reside, and all local secretaries were advised respecting defaulters, and a few subscriptions thus obtained.

Professor Attfield further reported that, at various times during the year, he had asked some seventy or eighty gentlemen to contribute results of researches to the annual meeting now about to be held, and he was happy to say that nearly thirty papers, all of pharmaceutical interest, had in consequence been promised.

At the close of the year Professor Attfield, finding that he had nearly one hundred pounds in hand, had ventured to spend most of it in asking chemists and druggists, not already members, to join the Conference. Throughout July he had issued the invitations, and more than 500 gentlemen had offered their names for nomination. Already £200 had thus been contributed to the funds o the Conference, and more candidates were daily applying for enrolment.

Various accounts had been paid since last meeting, as would be seen when the financial statements were read.

The Secretaries were duly instructed to remove the names of 115 defaulters from the lists of members.

Professor Attfield drew the attention of the Committee to five papers, which he thought might, perhaps, be considered unsuitable for the Conference. Abstracts of those papers having been given to the Committee, Professor Attfield was instructed to thank the authors for the contributions, and state that they were scarcely fitted as communications to the Pharmaceutical Conference.

The whole of the candidates mentioned were elected unanimously.

Mr. Brady proposed the name of Mr. William Saunders, of London, Ontario, as an honorary member. It was agreed that the President should bring the name of Mr. Saunders before the annual meeting.

Professor Attfield submitted a "programme of proceedings" at the sittings of the members on the following two days. With a few additions, the programme was agreed to.

Mr. Benger read a draft report of the Executive Committee, which was accepted.

Mr. Schacht, Treasurer, read a financial statement which had been prepared by the Secretaries, and signed by the Auditors.

The Treasurer also submitted the financial condition of the Bell and Hill's Fund.

Mr. Stoddart and Mr. Schacht stated that they were authorized by the pharmacists of Bristol to invite the Conference to Bristol in 1875.

Conversazione.

On Wednesday evening many members of the Conference, upon the invitation of the President, Vice-President, and Council of the Pharmaceutical Society of Great Britain, attended a Conversazione held in the Society's Rooms. An Exhibition of objects of interest in relation to pharmacy, of which some details are given in another column, was offered for the inspection of visitors.

Thursday, August 6th.

On Thursday, the Conference met for the reading and discussion of Papers at 10 a.m. The first business was the

Reception of Delegates.

The Secretary (Professor Attfield) having announced that, as a result of invitations he had issued, 500 new members had been elected, and that a fresh list of proposed members would be submitted on the following morning,—

Mr. F. B. Benger read the following list of delegates attending the Conference:—

Hull Chemists' Association.—Mr. Baynes,

Colchester Association of Chemists and Druggists.—Mr. J. B. B. Shenstone.

Leeds Chemists' Association.—Mr. George Ward and Mr. P. Jefferson.

Nottingham and Notts Chemists' Association.—Mr. J. H. Atherton.

Liverpool Chemists' Association.—Mr. Robert Sumner, Mr. John Shaw, and Mr. A. H. Mason.

Manchester Chemists and Druggists' Association.—Mr. Louis Siebold, Mr. F. Baden Benger, Mr. Wilkinson, and Mr. H. Woolley.

Midland Counties Chemists' Association.—Mr. Wm. Southall and Mr. H. W. Jones.

Dundee Chemists' Association.—Mr. Wm. Laird.

Brighton Association of Pharmacy.—Mr. Savage and Mr. Barton.

Bristol Pharmaceutical Association.—Mr. G. F. Schacht, Mr. W. W. Stoddart, and Mr. R. W. Giles.

Bradford Chemists' Association.—Mr. F. Bell and Mr. F. M. Rimmington.

Glasgow Chemists' Association.—Mr. Stanford, Mr. Frazer, and Mr. Fairlie.

Scarborough Chemists' Association.—Mr. J. Whitfield.

North British Branch of the Pharmaceutical Society.—Mr. Mackay, Mr. Baildon, and Mr. Young.

Professor Attfield said there were also present, as visitors from America, Mr. Edward T. Dobbins, member of the American Pharmaceutical Association; and

Colonel J. W. Forney, who desired to address a few words to the meeting.

Colonel Forney said—I feel deeply honoured, as the Commissioner of the United States Government, to appear before you in this somewhat informal way—not as a member of your body, but as representative of my country—with a communication to lay before you, and all bodies of a similar character, a few facts with reference to a great movement which has been set on foot by the American Government and people. I am a journalist in the City of Philadelphia, coming here rather as a rest from hard work than to undertake any such duty, but my people having understood that I intended to remain here for some time, have authorized me to communicate with the people of Great Britain, and with certain powers on the Continent, with reference to what is to us, and we hope will be to you, a most significant manifestation. On the 4th July, 1876, the American Government will be one hundred years old, and we propose to commemorate that event by an Exhibition to afford such proofs of our material and mental progress as will, we trust, be not unacceptable to the people of other nations. I feel somewhat appalled, at my position as a citizen of a young country, in venturing to lay before the representatives of this great English people, the reasons why we invite you to come to Philadelphia on the 4th July, 1876, and I should certainly feel appalled by the contrast between our young growth and your riper development, if I did not feel, after all, that we were the offspring of your laws, your literature, your religion, and your general example. In coming therefore to speak to you, I feel in some sort that I am speaking to my own people, by the same language, a language which in course of time must conquer all others. Philadelphia was laid out by an Englishman, William Penn, who lies buried, I believe, in Buckinghamshire, and whose grave it is my intention to visit, so that I may there draw some inspiration from the memory of the founder of Pennsylvania. That city, founded in 1668, has to-day a population of nearly one million. Her institutions of learning are perhaps not unknown to you. Her Academy of Fine Art, her Philosophical Institution, her Franklin Institution, and her various monuments for the promotion of science, particularly with reference to that branch which you represent to-day—chemistry—are not unknown either here, or in other parts of the world. The Government of the United States passed an Act of Congress on the 4th June last to encourage this celebration of the close of the century of American civilization. The State of Pennsylvania has raised over one million pounds sterling for the promotion of this great object. We do not come here to ask your pecuniary aid, but simply that you will send us such specimens of science and art as will be an invocation and encouragement to our own people; in return for which the Government of the United States has passed a law putting all objects or specimens that may be loaned to the Exposition on the free list, so that if your goods are sent by our American line of steamers, their safety will be insured. It is the intention of the thirty-seven States of the Union to contribute to this Exposition, and I think, therefore, you will see that we intend and desire, by asking your contributions, to present to you something that will not be unworthy of your own inspection. With these remarks I beg to thank you, in the name of my country, for the generous welcome you have given me.

The President said the proposed Exhibition was a long distance off at present, but he had no doubt that, in some way or other, English pharmacy would be represented there.

Mr. F. B. Benger next read the following report of the Executive Committee:—

Report of the Executive Committee.

Your Committee have little of importance to report since the last annual gathering. The work of the Conference having been chiefly of the ordinary routine character—a kind of work necessarily increasing in connection with so large an Association—it has devolved mainly on the Secretaries.

At a meeting of your Executive held on January 22nd, considerable discussion took place as to the most convenient date on which to hold the annual meeting for 1874. On previous occasions the Conference has assembled at the time and place of meeting of the British Association, and your Committee has therefore hitherto been relieved of the responsibility of deciding in the matter. It was finally resolved that the meeting should take place in London, on August the 5th and 6th, the house of the Pharmaceutical Society having been kindly placed at the service of the Conference. The Committee was further informed by Mr. Hills, President of the Society, that the Council over which he presided was most anxious to afford every facility for promoting the success of the Conference. It was also resolved in connection with the meeting once more to hold an exhibition of Pharmaceutical novelties and articles of interest, as it was felt that the objects of the Conference would be greatly promoted by such a course.

Appointment of Editor.—At the same meeting of your Committee, applications from eight candidates were read, and also letters relating to the editorship, and the merits of the candidates from various members of the Committee unable to be present. After a full discussion and careful deliberation, the election fell on Mr. Louis Siebold, Lecturer at the School of Pharmacy of the Manchester Chemists' Association.

Bell and Hill's Research and Library Fund.—A motion was carried authorizing the Treasurer to sell one bond of £50, and to expend the proceeds in aid of research or otherwise, according to the instructions of the Committee.

It was then resolved that £5 be placed at the disposal of Mr. Gerrard, to defray the cost of materials to be employed in a research on the official and other plasters; £10 had been forwarded to Mr. Groves to defray expenses incurred in further study of aconitines; and £10 to Dr. C. R. A. Wright to assist him in his researches. Reports by two of these gentlemen will be read at the present meeting. Ten pounds worth of books, bound in calf, and stamped with the Bell & Hill's device, were forwarded to Bradford, and duly acknowledged by Mr. Rimmington on behalf of the Chemists' Association of that town.

Assistant Secretary.—Mr. Robert Higgins Davies, F.C.S., has been appointed to this office.

The Year Book of Pharmacy.—The late date of the last Annual Meeting, and the sudden departure of the Editor for India, caused ten days' delay in the publication of the 'Year Book.' The volume, however, was issued on the 6th of January, and at once distributed to every member who had paid his annual subscription.

Exchanges for the Year Book.—Efforts have been made by the junior secretary during the year to establish exchanges with editors of scientific journals at home and abroad. The result has been, that some of the leading journals, treating of pharmaceutical matters, in England, France, Germany, and America, are now received regularly by the editor of the Year Book in exchange for our annual volume.

Circular respecting Unusual Doses.—Professor Attfield communicated with the officers of the Conference and with Mr. Hampson on this subject, and the resolutions of the Conference, preceded by an introductory letter, were printed in the form of a circular, nearly five hundred copies of which were posted to the leading physicians of England, Scotland, and Ireland. Although no answer to the circular was requested, several letters commendatory of the course adopted by the Conference were received. The medical and pharmaceutical press generally also gave favourable notices of the matter. Further, written copies of the circular letter, signed by the President of the Conference, were sent to the Presidents of the General Medical Council and Colleges of Physicians of London, Edinburgh, and Ireland, accompanied in each case by a short private note from the President of the Conference. From the English college a letter was received promising that the subject should be brought before the college at the earliest convenient opportunity.

At a meeting of the Committee held last evening, Professor Attfield reported that 200 subscriptions had been paid since the last meeting of the Executive. The names of 115 members whose subscriptions remained unpaid for three or four years, and to whom repeated applications had been made, were ordered to be struck off the list. He had recently sent an invitation to membership to every chemist on the register not already a member of the Conference. In reply to this, 500 new members had already sent in their nomination papers, and these gentlemen were duly elected.

Your Committee cannot close their report without an expression of deep regret at the loss sustained by the Conference in the death of Henry Deane, its first President, and the joint author with H. B. Brady, F.R.S., of the following papers, published in our transactions:—(1) Microscopic Research in relation to Pharmacy, 1864; (2) Microscopic Analysis, applied to Pharmacy, 1865; (3) Examination of Extract of Flesh, 1866.

Mr. SCHACHT (Treasurer) presented the financial statement as follows:—

The Treasurer in account with the British Pharmaceutical Conference.

Examined and found correct,

MICHAEL ROGERSON,
ALFRED ALLCHIN, } *Auditors.*

Mr. GILES (Clifton) moved the adoption of the report and financial statements.

Mr. HAMPSON seconded the motion, which was carried unanimously.

THE MEETING IN 1875.

Mr. SCHACHT, as chairman for the time being of the Bristol Pharmaceutical Association, begged leave to state that if the Conference should decide on coming to Bristol next year, as was anticipated, the chemists and druggists of the neighbourhood would be extremely gratified, and would do their utmost to make the gathering successful in all respects.

Mr. STODDART begged to second and cordially endorse the invitation.

The PRESIDENT having thanked both gentlemen and the pharmacists for the invitation, proceeded to read the following Inaugural Address:—

ADDRESS OF THE PRESIDENT TO THE MEMBERS OF THE BRITISH PHARMACEUTICAL CONFERENCE.

It will be known to most of those whom I have the honour of addressing that the original scheme of the British Pharmaceutical Conference did not embrace the contingency of a session held in the metropolis. It was intended to be a peripatetic Society, accompanying the wanderings of its elder and more powerful sister, the British Association for the Advancement of Science, of which organization, indeed, some aspiring souls hoped to make it a section or sub-section.

Until this year we have found no difficulty in adhering to our programme, and, however distant our place of meeting, have found a sufficient number of devoted pharmacists to wend their way thither. and there uphold, to the best of their power, the credit of British pharmacy, endeavouring to convince an unbelieving public that a chemist and druggist's occupation involves something more than the mixing of drugs at the order of a medical superior, and urging, both by precept and example, upon the local chemists, the necessity of union, of cultivation of that professional feeling that should animate every member of a scientific and honourable calling, and suggesting, where it was needed, the formation of local associations, the institution of libraries, in the formation of which it was enabled, by the generosity of one of its leading members, to give effective aid, in the shape of money grants, and generally endeavouring to carry out, to the best of its ability, the programme originally sketched by the founders of the Conference.

The result of ten years of such work has already been reviewed in the last annual address of the retiring President, and it is pleasant to think that, in the opinion of so competent a judge, our efforts have been crowned by a large measure of success.

It would need no gift of prophecy to foretel that so long as the same spirit animates the Conference that has inspired it hitherto, so long will it continue to flourish, so long will it powerfully second the efforts of the Pharmaceutical Society in raising the condition of British pharmacy, and improving the status of the British pharmacist.

It will be necessary now to advert to the reasons that have induced the Conference to deviate from its usual course, and, instead of accompanying the Association to Belfast, to decide on holding its session in London. But first let me acknowledge, without further delay, the courtesy that prompted the Council of the Pharmaceutical Society, in offering, through its President, for the use of the Conference, this lecture-hall for our meetings, and generally the use of its rooms, unrivalled in their special adaptation to our purposes, and further, the promise to afford every facility for the success of our meeting, a success which I, holding so responsible a position, am delighted to consider as now absolutely certain.

It seems that, early last year, inquiries were set on foot to ascertain what the feelings of the bodies representing in Ireland the pharmaceutists and chemists and druggists of this country, were, as to the feasibility of holding a successful meeting in Belfast, during the visit of the British Association. The answers received were unanimous in their deprecation of any such meeting being attempted during the continuance of the differences between the Irish apothecaries and the chemists and druggists of Ireland. Subsequently, on May the 29th, a deputation from the former body was received by the Council of the Conference, and the result arrived at, after long deliberation, was this: that, considering present circumstances, it would not be advisable to hold the 1874 meeting of the Conference in Belfast.

The reasons urged by the deputation, who were very polite in their expressions of admiration for the excellent work performed by members of our organization, showed that the Irish apothecaries were smarting under a sense of injury in consequence of the threatened encroachments of the chemists and druggists on their long-enjoyed privileges, and that, in fact, they declined to meet them as brethren, or countenance in any way their pretensions.

The Apothecaries' Hall of Ireland was instituted by Act of Parliament, 31 George III. cap. 34, which provides for the examination of candidates for the title of apothecary. To this body of examinees is exclusively confided the right to dispense the prescriptions of the medical profession. The original intention of the Legislature, it would seem, was to provide an adequate supply of apothecaries pure and simple, but somehow the curriculum demanded embraced the essentials of a medical education—included, in fact, medicine, surgery, midwifery, and anatomy, all of which subjects the candidate was compelled to pass in, even if he were desirous of limiting his practice to pharmacy only. The practical result was this, that as a medical qualification the diploma of the Hall was not much valued, and the course of study necessary for obtaining it entailing considerably more expense of time and money than a mere pharmacist would be justified in incurring, the labours of the examiners under the Act became lighter and lighter, until the fees for diplomas, at ten shillings each, averaged £10 only per annum. The public inconvenience caused by this limitation of the supply of dispensers, coupled with the feeling of injustice under which the chemists and druggists, many of whom were men of good position and education, laboured, gave rise to an agitation for an alteration of the law in the direction of the Pharmacy Acts, the operation of which had been of such advantage in the case of Great Britain.

The monopoly was not merely injurious, whole districts being deprived, by its influence, of competent dispensers, but absurd. It was competent for one apothecary to open any number of dispensaries, which he might or might not superintend personally, and regarding compounders he was under no restriction as to their selection. It was, and is, possible for the assistant at the druggist's of to-day to step across the road to-morrow to the apothecary's, and there accept an engagement in the higher branch of the business.

It is, therefore, I think, much to the credit of the apothecaries that in their Bill they have voluntarily proposed to trammel themselves with provisoes that limit the employees of the pharmaceutical chemist and apothecary to persons who have proved their capability before an Examining Board. A fair amount of time would of course have to be given those now engaged in the business to prepare for meeting the examiners, then there would be an exodus of the idle and incompetent, and matters would speedily arrange themselves in settled and permanent fashion. There need, I think, be no fear of opening and reopening of doors by which the idle are encouraged to postpone the evil day when they would have to withdraw somewhat from frivolous pursuits and take to hated study. A time having been fixed, it would, it is to be hoped, be strictly adhered to.

Many pharmaceutists on this side of St. George's Channel would rejoice if similar provisions could be ingrafted on our Pharmacy Act at some not distant day; but for the arrival of that day we must not be too impatient.

The Irish pharmacy question, being still *sub judice*, I would venture to insist on the great importance of compelling every student, apprentice, and assistant to pass an appropriate examination, and to suggest that, in the event of two grades of pharmacists being instituted, each grade should have its own distinctive title, and not be permitted to use any other, so that the public might be able, without difficulty, to recognize the distinction.

I am of opinion that great and, I fear, permanent injury has been done to pharmaceutical education in England by the omission of some such precaution. The public has been perfectly bewildered by the variety of titles assumed by holders of the lesser qualification, and remains to this day, and probably will remain till the end of the century, entirely ignorant of the distinction between things that differ so much as the Minor and Major qualifications. And it is not necessary to adopt Carlyle's estimation of "the public"—"some thirty millions, mostly fools," to account for such a state of things. What is the result? Young men, not unaware of this, concluding that the "title" is of no pecuniary value, and urged by no higher considerations, decline to undergo the expense and trouble of obtaining it. One cannot expect otherwise. It is as true now as ever it was that the belly is the real

"Magister artis, ingeniique largitor,"

deducting perhaps one per mille, the rest of mankind are ruled in the main by considerations of profit. Martyrs were never an abundant commodity; they are, I fear, becoming rarer every year.

I am led to these remarks by comparison of the Registers of 1873 and 1874, where I find that in 1873 the examined pharmaceutists were 8·93 per cent. of the total number, 12,750, whilst in 1874 they were but 8·92 per cent. of 13,216; the actual numbers in 1873 being 1138; in 1874, 1179; the increase—41 examined pharmaceutists, corresponds to a total increase of registered chemists and druggists of all kinds of 466. On the other hand, the chemists and druggists who have passed the Minor only have increased their percentage in the same interval from 7·87 per cent. to 10·59 per cent. I am aware that nothing is more deceptive than figures, unless it be facts, and therefore will abstain from forcing a construction of these figures upon this meeting. I fear, however, it must be confessed that the candidates for the Major examination bear no tolerable proportion to those for the Minor.

The evil might be partially met by the adoption by general consent of *one appellation only*, by all Major associates. Let me suggest Pharmacist (Major). It will, I hope, be understood that my object is not the glorification of the individual, but the conferring upon the title so much of distinctiveness that it might in a reasonable time become sufficiently appreciated by the public to be considered worth some effort and expense on the part of the rising generation.

I fear, however, the rising generation will find some difficulty in acquiring the instruction necessary for obtaining the distinction. Although the School of Pharmacy of the Pharmaceutical Society of Great Britain is but thirty-two years old, one already feels inclined to look back upon its earlier years as upon a golden age that has, alas! passed away. One looks with regret at the statement in the Calendar that in 1843 its lecturing professors numbered four, each one the most distinguished in his department of that day—George Fownes, F.R.S., Chemistry; Theophilus Redwood, Ph.D., Practical Pharmacy; Anthony Todd Thompson, M.D., F.L.S., Botany; Jonathan Pereira, M.D., F.R.S., Materia Medica. It is true the quality of our lecturers has not deteriorated, but their number has been halved, and, worse again, the length of each course has also been halved, in order, it would seem, to meet the demand for "rapid preparation," not to use a shorter and far uglier expression. But where is this to end? Is the School of Pharmacy of the Pharmaceutical Society of Great Britain to descend into the arena and compete with proprietary schools of pharmacy? The old objection of the impropriety of an examining body being also an educating body has of late years been frequently raised, and as often refuted, but I am not sure that now it could be done so easily. It seems to me that the difficulty will soon have to be faced, and the connection now existing between the two bodies severed. Disappointed candidates, it is well known, have ascribed their want of success to the partiality of the examiners for the students of their own schools, and now very recently a professional "crammer" has gone far beyond that, and not scrupled to print and distribute in a circular, addressed generally to students, that he will deliver a course of thirty lectures, etc. "The lectures will review each subject thoroughly, and point out the various tricks and artifices employed to pluck candidates."

The examiners were, of course, aware of the existence of this circular, and feeling themselves strong enough in the good opinion of the world to disregard it, have so done. In that, perhaps, they have done wisely. George Herbert has written—

> "Think not thy fame at every twitch will break,
> By great deeds show that thou canst little do;
> And do them not: that shall thy wisdom be."

But that feeling can be carried too far, and I am not sure that it has not now reached its limit. Should the Society be contemplating any such severance as I have indicated, it would seem only fair to the present staff of professors that it should not be long delayed, lest the ground be already covered, and they left out in the cold.

What seems to be really wanted is a chartered and endowed College of Pharmacy, that should confine its labours to the providing a high-class scientific education for intending Pharmacists. I believe that no such scheme would pay as a private speculation, and that one such, placed in the metropolis, would suffice for the whole of Great Britain. For the endowment of professorial chairs, one might look hopefully, perhaps, towards the Pharmaceutical Society and the wealthier members of our profession.

The School of Pharmacy of Paris, with its staff of twelve professors, and a three years' course, has, at the present time, 500 students attending it. In addition to these must be reckoned those attending the provincial Superior Schools of Pharmacy.

The recent change in the mode of conducting the Preliminary examination will, I think, meet with general approval as a step in the right direction. I think, however, that public opinion will eventually declare in favour of our delegating that office to one or more purely scholastic boards. That is already my opinion.

The reports of the examiners have of late revealed a most lamentable proportion of failures, especially in the Minor. The result is mainly due probably to the prospective increase in the stringency of that examination in October next. Young men, conscious of weakness, are rushing in, hoping by some fluke to pass the ordeal. One is compelled to wonder how or why such men enter the trade, and to speculate on their career as assistants.

The future of British pharmacy, with the present state of which the great mass of pharmacists are so profoundly dissatisfied, will depend in great measure on the class and condition of the young men introduced into the trade as apprentices and students. It has unfortunately been for many years the custom to regard an apprentice as a cheap labourer, and boys, if capable of plenty of work, no matter how ignorant or how rough in manner, were considered eligible for the post. Having no fear of examination before their eyes, they acquired what is called a practical knowledge of the business, and in due time commenced on their own account to keep open shop, as their employers had done before them. In that way, the country has been filled with chemists, with little scientific knowledge and less professional feeling, who, if they succeed in making a decent living, are therewith content, regarding the excelsior aspirations of their brethren as great rubbish. The great, but I hope not increasing, difficulty of finding competent assistants, obliges one to deal tenderly with young men of this class. Proprietors of mixed businesses are, I believe, the chief sufferers from this scarcity, and I fear that their troubles are likely to become more severe than otherwise. Every one sees and knows what the end will be. Young men of education, and presumably of refinement, will decline to do porter's work, and a separation of duties, and possibly of establishments, will be the result.

Every lover of advanced pharmacy will, I am sure, declare this to be a consummation devoutly to be wished.

The necessity, now I suppose generally understood, for a youth to pass certain examinations before entering business, has influenced and will continue to influence for the better the *personnel* of the trade. For an employer to take a premium from the parents of a youth, who he has reason to believe will never be able to enter the trade as a master, would be worse than robbery—not only is the money wasted, but what is of far greater value the youth's time; and it is satisfactory to think that such cases are now of very rare occurrence. Still, many years will, I fear, elapse before we shall be able to tap the right spring, and introduce into our ranks any great number of youths of gentle origin. Parents and guardians who have well-conditioned boys to place out in life are accustomed to well consider the matter before deciding.

The youth has perhaps seen at a popular lecture some brilliant experiments in chemistry, and forthwith decides that he will be a chemist. But his less impressible guardian before consenting counts well the cost of such a step, and finding that the mere fact of his being a chemist would, in the eyes of his friends, lower him in the social scale, and be a bar to his entry into the society of his quondam associates and equals, declines to give his permission, and the youth goes, as a matter of course, to swell the already overcrowded ranks of one of the recognised professions.

Popular ignorance on scientific subjects is still so astounding that the general public is quite unable to realize the fact that scientific medicine is impossible without scientific pharmacy, and I think it must also be acknowledged that the ordinary run of practitioners in medicine are not half alive on the subject. High-class pharmacy might here and there be received with favour, especially in large centres, and by the eminent of the profession; but, as a rule, a well-educated pharmacist would find himself unappreciated, and his carefully acquired knowledge daily growing rusty for want of use. Magistrates and public bodies in general would first apply for a chemical opinion, not to a professed chemist, but to a medical man, who, having been examined at the medical school on no end of ologies, must necessarily in their opinion be the best authority on any scientific point.

In days gone by, there were encyclopædists; there were also, at a remoter date, megatheriums, but both have disappeared for ever. Such is the vastness of the field of scientific investigation at the present day, and such the minuteness with which it is worked, that it is simply impossible for one intellect to grasp the whole or any considerable fraction of it.

In order to obtain a useful and a fruitful knowledge of any subject, attention must be concentrated upon it. We might even go further, and state that the whole of either of the more expanded sciences is too much for any one intellect to know and use effectively. Witness chemistry, whose successful cultivators in the present day have earned distinction by concentrating their attention on one or two departments of the science. It perhaps would not be too much to say that a life's work is to be found in opium, in Peruvian bark, in digitalis.

If the pharmacist claims, as his department of scientific work, the chemistry of drugs and of disease, he will have claimed enough and have done something to relieve the overtaxed capabilities of his medical coadjutor, and enable him, perhaps, to do what his distractions now so often prevent him from doing—tread the difficult path of original investigation.

So much has been said and written on the operation of the Adulteration Act, that I shall, I fear, in referring to it at all, be telling a thrice-told tale. The conception of the Act was doubtless laudable in the extreme, and by no class of persons was it more sincerely welcomed than by the honest tradesman, who saw in it a defence from the dishonest competition from which he so frequently suffers. The operation of the Act has, however, been far from satisfactory, and the good it has undoubtedly done in checking adulteration has been more than counterbalanced by the injury inflicted on innocent traders. And this has been caused mainly by a straining of the Act on the part of the lawyers, by sensational evidence, and by the lack of commercial knowledge and even of common sense on the part of the analysts.

The greatest sufferers have, I suppose, been the grocers, who have been repeatedly fined for selling as tea what had really been received as such at her Majesty's Custom House, and upon which duty had been paid; for selling as coffee the usual mixture of chicory and coffee, which every one expects to have when he buys the cheap article, and which many prefer to the pure, the packet all the time being labelled plainly, "This is sold as a mixture of chicory and coffee." But the magistrate ruled that that was not sufficient; it ought also to have been declared by word of mouth. In the sale of butter, also, they have been much harassed, the Liverpool case being a notable one, costing a large sum of money in the defence, and after the usual conflict of scientific evidence, ending in the acquittal, and possibly the ruin, of the butterman.

The milkmen have probably furnished as many cases as any, and in most instances have suffered deserved penalties, for I suppose no article of food has been so systematically tampered with as milk. Yet the dealer who had it proved against him that he had removed the cream, selling skim milk when ordinary milk was asked for, and therefore committing a fraud, was allowed to escape scot-free, because he had *added* nothing to it, whereas his neighbour, who, according to the analyst, had sold, as pure, milk containing an adulteration to the extent of five per cent. of water, was punished!

Finally, the chemist has had his turn. The great citrate of magnesia case depended on the use of a popular, and, if you will, an incorrect designation of a well-known article, and was exempt from even a suspicion of fraud or carelessness. Yet the seller was fined and his business so injured that he had to leave the neighbourhood.

The *bonâ fide* nature of the sale of sweet nitre cannot be doubted, nor can the case that arose from it be described otherwise than as a straining of the law to catch a man who ought never to have been put in jeopardy.

If one commercial fact is more firmly fixed in a chemist's mind than another, it is this—that Howard's preparations are always to be relied upon for purity. Yet we find a most respectable man indicted for selling as citrate of iron and quinine, an article adulterated with cinchonine, that article having been supplied by Messrs. Howard who explained the slight difference observed by the fact of the article having been overheated during preparation.

The scammony prosecutions again point to a most unsatisfactory state of things, and must have caused many an honest pharmacist to wonder whether it would be his turn next to defend his reputation on some trumpery charge.

The report of the Select Committee on the operation of the Adulteration Act has been generally received as satisfactory: it is therefore much to be regretted that the state of public business will not permit of action being taken upon it this session.

The amendments suggested by the Committee are both numerous and important. It was found that some magistrates, regarding the charge as a criminal one, would not allow the defendant to give evidence. That manifest injustice is in a fair way of being remedied; both the defendant and his wife are recommended to be allowed to enter the witness-box, and explain what very often they only would be able to explain. Then again it is recommended that when an article purchased of a wholesale dealer under guarantee is found to be adulterated, the wholesale dealer should be summoned as well as the retailer. This will be a great boon to pharmacists, who will, I have no doubt, very generally avail themselves of the guarantee system, and be content to pay accordingly. The pharmacist will, however, I should imagine, be held liable for manifest carelessness in not detecting what ought to have been self-evident. He, of all tradesmen, should be the last to shelter himself by a plea of ignorance; but as for his being expected to subject every one of the thousand articles in which he deals to chemical examination, it is simply absurd.

The report treats the analysts very fairly, but admits that some have shown more zeal than discretion, that others have shown a want of chemical knowledge, and recommends that the latter class should be weeded out by subjecting them to a practical examination. It has been affirmed, on good authority, that some of these gentlemen have set up as analysts after a three months' course only of chemistry, and that, in one case at least, undertaken after the receipt of the appointment. We need not wonder, then, at the occasional display of incompetence.

A main cause of the breakdown of the Act has been the difficulty of obtaining competent analysts possessing a requisite amount of commercial knowledge. It is suggested that in a few years' time there will be an abundant supply of *reliable scientific analysts*, and that, until that time, consolidation should be recommended. But a few years will not give a man the experience that would justify one in placing the reputation, and therefore the living, of a tradesman in his hands. In not taking precaution to prevent the introduction into court of cases of a doubtful character, the Select Committee have scarcely shown sufficient appreciation of the extreme delicacy of a tradesman's reputation. It seems that no discretionary power is to be conferred on any one. Should the analyst's certificate report adulteration to the extent of, say, 1 per cent., the inspector must cause a complaint to be made before a justice of the peace, and thereupon such justice shall issue a summons, etc., whereas it would seem that the justice of the case would often be met by a caution sent privately by the bench, on the recommendation of the analyst.

Cases have already occurred where, technically, the dealer was wrong, but practically, right, so that, after suffering all the annoyance and injury attending a charge which was really unsubstantiated, he still had to pay costs and a nominal fine. This reminds one of the recommendation to mercy of a west country jury, who, when asked their reason for the recommendation, answered, through their foreman, "Because, sir, we don't think he ever done it."

The plan that I should approve of would be this:—Abolish all local appointments of analysts, and establish at convenient points some five or six analytical laboratories, each superintended by a gentleman of eminence and experience as a chemist, and with some acquaintance with commerce and manufacture. Under him should be placed two or three juniors, who should receive from their superior numbered samples for examination. Each sample received should be twice examined, the analysts being unaware of the source of the samples before them. No sort of collusion could then be practised. On the results being returned to the superintendent, it should be his duty to compare them; if they were alike he would probably conclude that they were exact; if they did not tally, he would inquire the reason why, and direct, or undertake for himself, a further examination. His report to the justices, recommending prosecution or otherwise, might then be acted upon without much danger of inflicting injustice.

The analysts should, of course, be paid by salary, and not by fees, and the right of appeal should be conceded.

An omission, evidently a slip on the part of the authors of the Act, will be supplied, and the fraudulent abstraction of important properties of any commodity will be regarded as a punishable offence.

There is, I am happy to say, some hope of the present Act being practically suspended in its operation until it has undergone amendment.

The question of co-operation remains *in statu quo*: but occasionally evidence is afforded us that such associations are subject to the same misfortunes as other trading concerns. The announcement of the demise of the Universal Drug Supply Association, Limited, did not probably evoke any sincere regrets on the part of London pharmacists.

It is not likely that any action will or can be taken on the general question in the way of repression, but it is still open to question whether the servants of the Crown ought to be allowed to devote their spare time and official training to trading with the general public, to the injury of the shopkeepers who contribute so largely to the taxes out of which their salaries are paid.

The system, if fully carried out, would simply obliterate the middle classes. Should that consummation ever be arrived at, I fear the saving of 5 per cent. on the incomes of the rich will fail to repay the inconvenience the plutocracy will suffer on being brought face to face with the proletariat.

We are likely, if not wide awake to the fact, to be peculiarly injured by this style of trading. Co-operators cannot get advice from the store; they will therefore go to the local chemist for it on pretence of some trifling purchase. We must therefore be on our guard against this gratuitous brain-sucking.

I should like to say a word or two about the trade in patent medicines, a subject to which the attention of the Legislature ought, I think, to be directed. I find that during the financial year ending March 31st, 1873, stamp duty was paid on no less than 12,731,753 packages of patent medicines—considerably over a million more than during the previous year. The revenue thence derived amounted to £95,812 for stamp duties on the medicines, and £7,283 for excise duty on patent medicine vendors. The aggregate of these sums is, of course, a mere bagatelle in the revenue of this great country, so that financial considerations need not be regarded in considering the question whether or not it is advisable that the present system should be continued. I regard the whole system as rotten, and believe it to be productive of great evil. For to what has advertising patent medicines now sunk? It is in the main (I allow some honourable exceptions) a systematic exploitation of the ignorance and credulity of sick people, and, therefore, calls loudly for some sort of regulation, if not extirpation. The medical profession, who are more nearly concerned with the public health than are the chemists, will best appreciate the extent of the evil, and to them rather it appertains to suggest a remedy for the abuse.

At a meeting of the Society of Pharmacy of Paris, it was announced by M. Boudet, that the committee appointed for the purpose had prepared its report on the International Pharmacopœia in readiness for presentation to the St. Petersburg Congress. The nature of the report did not transpire. It is to be hoped that its recommendations will not be too elaborate, a failing to which the French are inclined, and that the attention of the Congress may be fixed on assimilating the formulæ for the preparation of a small number of what may be termed heroic remedies.

The number of drugs actually necessary for the treatment of disease by a true physician is comparatively small, and one can venture to hope that if the scope of the International Pharmacopœia be limited to these, something might be effected in this generation. The Denarium Medicum of Bernardus Penotus, published at Berne in 1608, proposes to show how all internal diseases may be cured by the ten remedies he describes. Isaacus Wollandus requires three only; Paracelsus only one, and justifies himself as follows:— Out of the trunk of one tree you may carve as many as 600 images, but one fire will consume the whole of them. In the same way, the various kinds of disease which are almost innumerable, may yet with one not over-violent remedy be all cured." It has already been decided that the text shall be in Latin, and the weights used the metrical. Professor C. W. Thomas, suggests that proportional parts by weight would be more convenient at the present; but I do not see how, when the dose comes to be apportioned, a definite unit can be dispensed with. His other suggestion—a general Pharmacopœia for all English-speaking communities—is a very good and seemingly practical one. The Germans and the Scandinavians have already accomplished something of the kind, but their task, owing to the absence of colonies, was a comparatively light one.

When works of this magnitude have to be undertaken, we look around for men equal to the occasion, but every year, unfortunately, it is the melancholy duty of the president to have to refer to the removal of one or more of the pillars of pharmacy. This year the task is especially heavy, as we have lost in Henry Deane our first president, who, if not the originator, may truly be styled the founder, of the Conference. It was to his wisdom, displayed in guiding the course of the Conference during the first years of its existence, that we owe much of its present prosperity, and to him we were indebted for some of the best papers that have been presented to it. Mr. Deane's reputation as a man of science was, however, by no means limited to this field; his fame, more especially as a microscopist, was widely and generally known. His social qualities were better known to many present than to me. We never realize the value of a thing till we have lost it, and now it often occurs to me how foolish I was not to avail myself more frequently of opportunities of cultivating his society. Mr. Deane had his gay as well as his grave moments, and then no man could be more genial or amusing. I am not one to say "we ne'er shall look upon his like again," but am hopeful that the contagion of his example will spread among the rising generation, and produce equally good results in future years. We then shall be able to say, in the words of the epigrammatist,—

"Mira cano, Sol occubuit, nox nulla secuta!"

In Mr. George Dymond we have lost a useful and talented member, who has held office in the Conference, and to whom we often were indebted for remarks of great value in our discussions; he was also a contributor to our transactions. He died at the early age of 44, when to all appearance he had before him a long life of activity and usefulness.

We never again shall see amongst us the familiar form and genial countenance of Thomas N. R. Morson, who also has departed. Mr. Morson's reputation as a pharmaceutical chemist was literally world-wide. He was not only the first manufacturer in this country of many of the rarer chemicals, but was for very many years reputed the best. His connection with the Conference was, I believe, limited to membership. As a contributor to our discussions no man spoke with greater weight or was listened to with more respect. A few observations from Mr. Morson would make an otherwise sterile paper at once fruitful with good—in that capacity we shall much miss him. His death has left a void in scientific society that will not readily be filled up.

In concluding my address, which, I fear, has already become tedious, I will, as shortly as I can, refer to the action taken by the French pharmaciens when it was proposed to subordinate, in the French army, pharmacy to medicine. The movement was begun by the doctors, and on their representation referred to the Academy of Medicine to report thereon. In the end the doctors were defeated, pharmacy retaining its old independent position. The advocates on the side of pharmacy were MM. Bussy, Boudet, Poggiale and Dumas, the latter of whom, himself a pharmacien by education, delivered a speech full of sentiments worthy of remembrance by the pharmacists of England.

"If it be true, he says, that the pharmacien, in dispensing the prescription of the medical man, is really his subordinate, how is it in the case of the selection, preparation, and titration of drugs and preparations, in all of which most important operations the pharmacien is the sole responsible person, and for the control of which medical men are and must be wholly incompetent? '*On ne fait pas de bonne Chimie en passant*,' was a dictum of no less a person than Gay-Lussac, and the fact of a physician's time being so fully occupied by his medical duties, and rendered fragmentary by frequent and unexpected calls for his services, renders it impossible that he ever can be able to devote that continuous application to chemical details from whence alone proceed good pharmacy and sound chemical hygiene." "From the ranks of French pharmaciens have issued many distinguished discoverers. To mention those only who have departed, Rouelle, Baumé, the two Pelletiers, Robiquet, Serullas, Soubeiran, Pelouze, Balard." "Let medicine, then, exalt the level of its instruction, and extend the area of its services, all the world will applaud it for so doing; but let the Academy be convinced of this, that to diminish the importance of pharmacy is not necessarily to increase that of medicine. The art of healing cannot be separated from the highest chemistry; it needs its help at every moment, and if clinical studies and physiological experiments point the way, it is the chemical analysis of the normal and morbid products of the economy which sustain its steps and prevent them going astray."

The pharmacists of England, now in a very slow state of transition, will have some difficulty in realizing the feelings of their brethren across the water under the above circumstances. The time, however, will come when throughout Europe the position of pharmacists will be assimilated. It must not be forgotten that the desired change cannot be effected in a day by Act of Parliament. "They who would be free themselves must strike the blow," and the British pharmacist, in order to achieve the object of his ambition, must be prepared both to do and suffer in the cause. If trading instincts are allowed to smother professional feeling and practice, a trader he will and must remain; if otherwise, pharmacy will eventually in this country attain the status it has so long enjoyed on the Continent, and render services equally beneficial to the community.

Mr. Cayley, in proposing a cordial vote of thanks to the President, said: An able and interesting address we should expect from Mr. Groves, whom we have known for so many years, and whose writings we have all read. I doubt not that this meeting will, in all respects, equal, and probably surpass, the meetings which have been held in other places; and I am sure that Mr. Groves will acquit himself as the Presidents on previous occasions have done, and that we shall all have good cause to be pleased with his election. I will not comment on any portion of the address, which we shall have an opportunity of reading at our leisure, but I would make a remark on just one subject. We have lost three eminent members of the Conference, Mr. Deane, Mr. Morson, and Mr. Dymond, during the past year. Those who remember what the Pharmaceutical Society was twenty-four or twenty-five years ago, will recollect what very important members the two first-named gentlemen were. I look back with great pleasure to passing through the rooms upstairs when those two gentlemen sat as examiners; their kindness and their courtesy was such as could not be surpassed and I, for one, have great cause to remember them with respect and gratitude. I beg to propose that a cordial vote of thanks be given to Mr. Groves for his very able and interesting address.

Mr. Gostling: I have very great pleasure in seconding the motion. The address is so comprehensive that it would ill become me to attempt any comment on the various points which are introduced; but the wise suggestions which were made on the various matters so ably brought forward will doubtless receive the patient and careful consideration of every member of the Conference, in reading them. It is impossible for us to carry in our minds so many points as the President has brought before us, but there are many of great importance which will have to receive the consideration, not only of ourselves, but of the Pharmaceutical Society, such, for instance, as the prospects of the rising chemists, their titles and their qualifications, and their interests in the future. As fathers introducing sons into our businesses we feel great interest respecting them, and sometimes have some fear whether the next generation will do as well as the honoured generation before us have done. I have much pleasure in seconding the vote of thanks to the President.

Mr. T. H. Hills: As President of the Pharmaceutical Society, I beg to support this motion, and to offer to the President the best thanks of the Council and members of the Society, not only for this address, but for the honour that he and the members have done us in coming and occupying our rooms. I consider the Pharmaceutical Society and the Pharmaceutical Conference are one. I have the honour to hold the office of Vice-President of the British Pharmaceutical Conference, although I have done very little beyond looking on and saying, Go on, my young friends. I think they have made a capital commencement, and I am sure they will successfully carry out what they have begun so well.

The resolution having been carried unanimously.

The President said: Gentlemen, I can assure you, when I was proposed to occupy the very important position that I hold, I accepted it with great trepidation; and the matter of the address was to me a very serious affair. When I came to compose it, I found the number of subjects to be included was something alarming. I should have preferred giving a scientific *résumé* of the work done during the year, but these things are rather overdone in the present day, or are likely to be; and, therefore, I decided to follow the line I have adopted. In doing so, I am afraid I have trodden on the corns of not a few, and do not at all suppose that my opinions will meet with general approval; but I hope they may act as a ferment, and set others thinking, and do good in that way. There are many points of which I know I hold views peculiar to myself, but still I thought I was bound honestly to bring them forward. If you will only accept my effort in that spirit I shall be well satisfied.

(*To be continued.*)

EXHIBITION OF OBJECTS OF INTEREST RELATING TO PHARMACY.

This Exhibition was held in the rooms of the Society, in Bloomsbury Square, and commenced on Wednesday morning. We propose to give a short notice of most of the articles exhibited in the various rooms, in the order in which the rooms were numbered, but want of space compels us to reserve a considerable portion of this notice until next week. In the reception-room were two magnificent pictures of lions by Landseer, the truthfulness to nature and grandeur of which are too well known to call for any comment here. These and several other very valuable paintings were lent for the occasion by the President of the Society. A portrait of Pierandrea Mattioli, a celebrated Italian physician, botanist, and writer on drugs, and an old pharmacological work of his dated 1574, were exhibited by Mr. D. Hanbury. In this room also was an immense leaf of that magnificent water lily the Victoria regia, and a splendid flower of the same plant, which had been kindly sent for the purpose by Mr. Sowerby, the Secretary of the Royal Botanical Society.

Of the objects exhibited in room No. 1, the following are deserving of notice. An electrical recorder for registering time, speed, distance run, and number of passengers inside and out, of tram-cars and omnibuses, exhibited by Mr. Wildman Whitehouse, forming a very pretty and interesting apparatus.

Some photographs of fluorescent substances, showing that solutions of quinine, æsculin, etc., give figures as black as ink does, when photographed, and that figures drawn on paper with these solutions, although not visible to the eye, show black in a photograph.—Lent by Dr. Gladstone, F.R.S.

A series of thermometers used in experiments to ascertain the relative sensitiveness of different kinds of thermometers, and whether there is any regular law with regard to the increase of sensitiveness according to the decrease of size of the bulb.—Exhibited by Mr. G. J. Simmons.

Among chemical apparatus may be mentioned Beindorff's complete and very compact steam apparatus for pharmaceutical laboratories, from Zimmermann & Co.; a large and valuable set of apparatus, occupying the centre of the room, and Dr. E. A. Parkes' chemical cabinet for the analysis of food, air and water, from Messrs. J. J. Griffin and Son; Becker's scientific and chemical balances, combining great accuracy with a moderate price, from Mr. H. Gillman; milk testing apparatus from Mr. W. W. Stoddart, a full account of which will be found among the Conference papers; a bath for making suppositories, by Mr. E. R. Learoyd.

Elegant pharmacy was well represented in this room, and included sugar-coated pills, from Mr. Hampson; sugar-coated pills and pilules, from Messrs. Bullock and Crenshaw, of Philadelphia, the pilules being about the size of homœopathic pilules, and containing $\frac{1}{10}$ gr. of podophyllin, $\frac{1}{40}$ arsenious acid, and $\frac{1}{60}$ of strychnia respectively; soluble pearl-coated pills, syrup of erotonchloral, in which the taste was well disguised, and other preparations, from Messrs. J. Richardson and Co., of Leicester; castor-oil jelly, in which the taste of castor-oil could not be perceived, from Mr. R. Niven.

By Messrs. H. and T. Kirby and Co. were exhibited coated pills and glycerols; the latter being a kind of lozenge, made of glycerine and gelatine, in shape somewhat resembling Pate de Guimauve lozenges, and medicated with every imaginable medicine. They have an elegant polished appearance, and really look too tempting to contain nauseous medicines. The same firm also exhibits some very compact portable medicine chests, which can be carried in a great-coat pocket, and contain coated pills of all the more important drugs, together with a few of the most useful surgical appliances. Nor is elegant pharmacy restricted to human beings alone. Physic balls and other medicines, both liquid and solid, for horses and dogs, were exhibited, enclosed in gelatine capsules, so that "the merciful man may be kind unto his beast" in the matter of medicine, and ought to have no trouble in administering these tasteless boluses to the patients for whom they are intended.

Dropping and sprinkling stoppers are exhibited by Messrs. R. J. Ellis and Co., and will be a valuable acquisition to those who have to take medicine in drops, although scarcely applicable to very powerful medicines. These stoppers consist of a glass stopper with a slightly tapering end passing through and beyond a cork, the glass being enlarged above and below the cork, so as to admit of its being raised a short distance, and the tapering end of the glass thus fitting loosely to the cork, admits the passage of a small quantity of fluid.

Self-acting label cabinets, which consist of a set of drawers, weighted at the bottom, and suspended by wire at the sides, so that a touch on the handle of the drawer opens it, and when the label is taken out it swings back by its own weight. These were exhibited by Mr. Shephard.

Apparatus for consecutive percolation, and various pharmaceutical products of excellent quality obtained by this process, were exhibited by Mr. R. Giles; specimens of Cortex Rhamni Frangulæ and preparations made from it by Mr. H. C. Baildon; very neat poultice bags consisting of muslin on the side to be placed nearest the skin, and gutta percha sheeting on the other side, thus protecting the clothes from being stained, while the muslin prevents the poultice from soiling the skin, by Mr. J. Broad. M. Cornélis, of Diest, Belgium, exhibited through his London agent, M. Léon Vallez, his bottles for preserving vegetable or deliquescent substances indefinitely; these bottles have an ordinary hollow stopper, containing fragments of quicklime, which is prevented from falling into the bottle by a piece of leather fastened to a rim at the bottom of the stopper. In one of the bottles, violet flowers seven years old were as brightly coloured as if only dried yesterday, and conium leaves were as green and odorous as if collected this season instead of four years ago. Stramonium powder which was seven years old had not the least appearance or smell of dampness, but was as good as if just powdered. An interesting series of bottles containing extracts of meat, showing the proportion utilized and wasted in the several methods of obtaining the soluble portion of meat, and accompanied by a diagram, were exhibited by Messrs. Darby and Gosden. These specimens were to show that while by Liebig's process only a little more than a quarter of the soluble matter is extracted, and by the ordinary process rather less than one-third is extracted, the whole available amount is obtained by Darby and Gosden's process; also, that in stewing meat, the whole of the soluble matter is not extracted.

It is noticeable, however, that Darby and Gosden's extract is a fluid extract of the consistence of treacle, while Liebig's extract is almost solid, and the extract of meat prepared by the ordinary process is dry and hard so that the difference is not quite so great as at first sight, would seem to be the case.

In this room were also some very pretty seaweeds, including several rare species, such as *Carpomitra cabreræ*, *Gigartina pistillata*, and *Chrysomenia rosea*, from Mr. J. Gatcombe, of Plymouth.

Some rare and valuable specimens of curious alkaloids and other products of cinchona bark were exhibited by Mr. J. E. Howard; also some samples of Dr. De Vrij's sulphate of amorphous quinine, in powder. Mr. Meggeson exhibited a series of medicated lozenges, including those of the Throat Hospital. Among the latter may be mentioned lozenges of benzoin, guaiacum, logwood, cream of tartar, carbolic acid, and cubebs, the last being used as an anti-sialogogue. A magnificent specimen of cantharidine, as well as fine specimens of meconine, *Tela vesicatoria*, and liquid blister, were exhibited by Messrs. T. and H. Smith, of Edinburgh, as well as a large specimen of cryptopia, the new alkaloid discovered in opium, by the same gentlemen.

MEETING OF PUBLIC ANALYSTS.

A preliminary meeting of the public analysts of the country was held at the Cannon Street Hotel, on Friday, August 7, 1874; Dr. Redwood in the chair.

The following were present:—Mr. A. Winter Blyth, of Devonshire; Mr. Thomas Fairley, of Leeds; Mr. John Horsley, of Cheltenham; Mr. Wentworth Scott, of Wolverhampton; Mr. Wanklyn, of London; Mr. J. H. Gramshaw, of Gravesend; Mr. J. Wiggin, Ipswich; Mr. A. H. Allen, Sheffield; Mr. G. W. Wigner, London; Mr. C. H. Piesse, London; Mr. F. J. Burge, London; Mr. C. Estcourt, Manchester; Mr. J. C. Bell, Salford; Dr. W. H. Corfield, London; Mr. G. A. Rogers, London; Dr. J. N. Vinen, London; Dr. Thos. Stevenson, London; Mr. F. M. Rimmington, Bradford; Mr. E. W. T. Jones, Wolverhampton; Dr. Bernays, London; Dr. Tripe, London; Dr. Dupré, London; Mr. George Jarmain, Huddersfield; Mr. Charles Heisch, London.

The Chairman, in commencing the business of the meeting, said: Gentlemen, the objects of this meeting have been communicated to you by a circular, which I presume you have all seen, and to which I am very glad to find so general and cordial a response by the public analysts throughout the country, for those who have attended here on the present occasion are but a portion of the gentlemen from whom communications have been received. The immediate cause of our meeting has undoubtedly been the Report of the Select Committee of the House of Commons, in which it is recommended that certain alterations should be made in the Adulteration Act that appear to some of us to be very undesirable, and in which also there are certain remarks made in reference to public analysts that we think at least call for explanation. But although the report of the Committee, and some of the evidence upon which that report is founded, have been the circumstances which have prompted us to immediate action, there are, quite irrespective of those circumstances, sufficient reasons, we think, to justify the public analysts coming together on the present occasion, and associating for the purpose of promoting their common interests, and improving, as far as they can, the security for the performance of their duties efficiently. There are, therefore, three objects which are now before us; first, the refutation of unjust imputations; secondly, the repudiation of proposed measures of interference with our professional position and independence; and, thirdly, the formation of an association, having for its objects the promotion of mutual assistance and co-operation among public analysts. Now, these objects will all be dealt with in the propositions which will be submitted to the meeting, and I am very glad to see so many gentlemen here on the present occasion, who are fully able to deal efficiently with all that is required for the substantiation of our position. A good deal has been said in the evidence given before the Committee, and something also in the report of the Committee, which appears to me to be unfair and unjust to the body we represent. A disposition has been manifested to throw all the blame attaching to any imperfections in the carrying out of the Adulteration Act, upon the analysts; and in fact the analysts have been made a sort of scapegoat for the relief of other parties. Now, I am not prepared to say that all the analysts that have been appointed under this Act are skilled and experienced chemists, capable of undertaking the investigation of any case of food or drug analysis that may be submitted to them; but if there should be deficiency of qualification in some of those who are appointed, it appears to me that the blame, at any rate in great measure, rests, first, with those who have framed the Act, and, secondly, with those who are carrying it into execution. That the Act is defective is admitted by all, but there is one defect which I think has not been referred to so prominently as it deserves to have been. I allude to the definition which is given in the Act itself of the qualification of an analytical chemist. The highest, and only real and sound qualification, is made subordinate to one which is really of comparatively little importance. It appears to me that it has been a great mistake to put medical knowledge before chemical knowledge as a qualification for appointment to this office. And it is not to be wondered at that parochial and other local authorities should have been misled by the incorrect views which have been put before them as to the qualification of those to be appointed as analysts. Then the effect of making chemical knowledge subordinate to medical knowledge as a qualification, has been further aggravated by depreciating the value of chemical analysis—a result which necessarily must ensue from the naming of such a fee as 2*s.* 6*d.* for an analysis. Now, it appears to me that these are fundamental errors which have been committed, and which have caused many of the shortcomings and defects which have been complained of in the administration of this law. If chemical knowledge had been called into requisition, and credited at its true value,—although there probably may have been a smaller apparent, there certainly, I think, would have been a greater real amount of valuable work resulting from the operations under the Act. Under existing circumstances, however, the local authorities, with the imperfect guide afforded them by the Act which has been put into their hands, have been seeking for analysts possessing all the qualifications indicated in the Act, and willing to undertake the performance of a large amount of work for very little pay. Now, I should be very glad to see an amended definition of the qualifications of analysts under this Act, and some provision made for better and more uniform remuneration of the class of public analysts. If this were done, I feel assured that there would soon be a practical refutation afforded of the statement which has been put forth by Dr. Voelcker in reference to the number of competent analytical chemists to be found in the kingdom. But the report, after indicating that there are no qualified chemists to be found, seems to imply that they are to be produced to order at South Kensington, and there is not even much confidence apparently felt in this mode of proceeding, for it is proposed that the authority of the analysts, when certified even in that way, should be superseded by a higher authority at Somerset House. Now, I think, and the Committee think, that it is our duty to consider whether the suggested arrangements are likely to prove satisfactory and beneficial. The Committee who have called this meeting together have drawn up the propositions which will be submitted to you. There are a large number of these to be considered, and I hope you will give your best attention to the subjects as they are individually brought before you, and that, as briefly as is compatible with their due consideration, you will signify your opinion with respect to them. This is really the object with which we have met on the present occasion. I have one proposition, the first motion which was to have been proposed by a gentleman, Dr. Hassall, who is not able to be here to-day, who, however, signified his concurrence with what we are doing. I may state that, since the circular was issued, there has been an addition made to the Committee, first of Dr. Hassall's name, and since then of the names of Dr. Bernays, Mr. Estcourt, and Mr. Wanklyn. We propose those gentlemen to be added to the Committee. Perhaps before I proceed to put before you the first proposition, it may be as well to call upon one of the Secretaries, Mr. Wigner, just to indicate any information that he has to convey to you, as regards the extensive correspondence which has taken place between him and members in different parts of the country.

The Secretary: From published lists, as far as we have been able to obtain them, we found the names of 77 public analysts holding something like 110 appointments. Circulars were sent to every one of them, but as the addresses of some of them were imperfect, some six or more which were sent appear not to have been received. The number of replies received has been 57, consisting of the resolutions filled up and slightly altered. Of those all except two express themselves as favourable in almost everything with respect to the scheme. And to the names of those two I have put a query, because there are some points which are essential, as I think, to the success of the scheme, in which they differ from us.

The CHAIRMAN: Now, gentlemen, I will propose the first resolution, to the effect—

"That the analysts present at this Conference, having read and carefully considered the Report of the Select Committee of the House of Commons on the Adulteration Act, are of opinion that it is desirable to take this report into joint consideration, and to suggest amendments in the present Act, with a view to impending legislation next Session."

I need say nothing more than I have already addressed to you in support of this resolution.

The SECRETARY: The only suggestion which has been made with reference to this is by Mr. Wentworth Scott, to omit the words from "desirable" to the end.

Mr. A. H. ALLEN: I will rise, as a matter of form, to second the motion. I think the omission suggested by Mr. Scott does not bear very greatly upon the meaning of the resolution, and I hope we shall have very little difficulty in passing it as it stands; we are all so generally agreed upon it.

The motion was put and carried unanimously.

Dr. DUPRÉ: The second proposition has just been put into my hands—

"That the analysts present consider that the proposed reference of disputed cases to Somerset House Laboratory, or to any body of persons whose decision is to be considered final is objectionable, because it would supersede the skilled personal work of an analyst, the result of which had been given on oath, by the official work of a department for which no person could be held responsible. They are of opinion that no referee's decision in a disputed case should be accepted as final, unless it be given on oath, and tested by cross-examination."

There are but very few remarks necessary to be made in support of this proposition, and many remarks which I had intended to make have already been made in the speech of the Chairman. But, first, I would say that the proposition to appoint referees proceeds upon an assumption that many of the analysts' certificates that have been given have been wrong, and that in consequence a great deal of hardship has been inflicted. Now, I must entirely dissent from that. I have carefully followed all the published cases, and I must say that, with very few exceptions, I have not come across any case whatever where the analyst was wrong. I do not believe that the hardship has any real foundation in fact. Secondly, that as the law at present stands, the person against whom the analyst's certificate has been given has all the remedies he need have. He can have a second analysis made, which I believe has been only once or twice refused, and in case the second analysis is in his favour, the Board which has appointed the analyst must pay all the costs. Now, that is very good as it stands. I therefore really think it is not at all necessary for a Board of Referees to be appointed. But if it should be at all thought expedient to have a Board of Referees, it is absolutely essential that their certificate should not be considered final without their presence in court, and without their giving the analyst an opportunity of cross-examining them. Because I am quite convinced that no analyst who respects himself, who values his reputation, or who takes care of his word, and who does not give his certificate before he is perfectly sure that there has been adulteration, could for a moment submit to have that certificate set aside, by whatever authority it might be, without his having an opportunity of testing by cross-examination such a decision. I am far from saying that it is impossible to make a mistake,—for everybody is liable to mistakes,—but the analyst ought to have the opportunity of testing whether the referee has not made a mistake in his analysis.

The SECRETARY read the following extracts from letters he had received. Dr. Letheby objects to Somerset House and to Kensington, but thinks references should be made to responsible officers appointed by the Board of Trade or Local Government Board, as is the case at present with regard to disputes concerning the quality of gas in this metropolis. Mr. J. Shea thinks traders are fully protected, as a second analysis may be ordered, or the trader may appeal. Mr. C. H. Piesse suggests that chemical assessors should be appointed to assist the judges. Mr. E. W. T. Jones thinks there should be a fixed analytical authority for reference, of three good men, selected for their special knowledge; all of whom must attest the certificate, to be considered final. Mr. Scott suggested to insert the words, "if objected to by the analysts" (after the word "final"). Mr. Campbell Brown thinks "the best body would consist of three of the most eminent chemists of the country, nominated by the Local Government Board, or by the analysts, with the approval of the Local Government Board. They should retire in rotation periodically." Mr. C. W. Heaton writes: "Court of appeal necessary. Somerset House best now available for London. Actual referee analyst should give evidence on oath." Mr. Fairley thinks referees' work should be tested by other samples, sent at the same time.

Mr. WANKLYN: In rising to second this motion, I have to observe that the proposal to refer to Somerset House as a court of final appeal is to be objected to on this ground, that the authorities in Somerset House have no special knowledge of the work that we have to do, and that many persons who have been appointed as public analysts, or, at any rate, several of them, are more eminent than the people at Somerset House, and to refer to Somerset House would be to refer from higher to lower authorities. With regard to the proposition to have referees at all, there is something to be said for it; but there is only one Court of Referees to which I, for one, should be disposed to submit, and that is to the public analysts themselves as a body. We are more capable of doing this work than any body of people in this country, and I will make bold to say that, notwithstanding all that has been alleged against public analysts as a body, we are quite as respectable as the practitioners of medicine or surgery in this country as a body, or as the pharmaceutists as a body, and certainly as respectable as those persons who are named chemists in this country. And there is no Court of Referees which would have any authority, and which would be submitted to, except the general body of public analysts.

Mr. WENTWORTH SCOTT: I have some little experience which bears upon the proposed reference to Somerset House, and I know something of the way in which they perform their work in that department; and I, for one, should certainly object to any reference being made there of disputed cases. That Court of Referees, in any shape or form, will have to be an institution almost as definite as an Adulteration Act. I, for one, have no doubt that that Board of Referees must emanate solely and simply from our own body, and from no other source, and although there may not be a very large per-centage of our own body at the present time who have given their sole attention to the question of food analysis, or so much as one could wish, still that is a fault which will correct itself day by day and year by year, and in a very few years we shall be able to turn our attention so minutely to this particular subject, and in a manner that no other class of men will, that for referees, the public analysts as a body will be the only persons to supply them from among themselves. I have very great pleasure in supporting this proposition.

The CHAIRMAN: If no other gentleman has any remark to make upon it, I will proceed at once.

Mr. ALLEN: I would simply say, as the originator o the notion, in my evidence before the Committee, how thoroughly I endorse all that has been said with respect to the desirability of having a Board of Analysts elected by ourselves from our own number. I think we must agree that there is no one so fit to adjudicate upon such cases as those whom we know to be the best men. We know who are competent, and upon whom we should have personal reliance, on their honour and honesty, as well as on their scientific skill. And on that account it seems desirable that if any such Board should be appointed, it should really be by the analysts themselves.

Mr. RIMMINGTON: It was asked whether it is desirable to have the alteration made "unless accepted by the analysts" just before the last line.

Mr. WENTWORTH SCOTT: I thought that that very brief suggestion was simply to avoid complication, in case of there being no question of the matter. I thought as the party most interested, the analyst whose certificate is impugned, should have the power of objecting to the acceptation of a referee's decision unless it was given on oath and tested by cross-examination, or he should have the option equally of saying I am willing to abide by the certificate.

The CHAIRMAN: Perhaps you would allow me to state what the reasons were that induced the committee not to introduce that modification or alteration. It appeared to the committee that it would have the effect of giving a preference to the analyst over the accused party. Now, according to the usual understanding in matters of this description, the accused party is certainly supposed to be placed rather in a favourable position than otherwise. This would appear to be placing him in an unfavourable position. If the referee's verdict was against the accused, no further appeal: if against the analyst, further appeal admitted. Now it does not appear that there is really good ground for making this distinction, and we would rather wish it to appear that the defendant was placed in as favourable a position as possible, and that no preference or advantage was given to the analyst over him.

Mr. BLYTH: As it appears to be the general opinion that there should be a Board of Analysts appointed as referees or analysts, persons selected by our own body as referees, I put it to the public analysts present whether it would not be better to modify the proposition somewhat, and instead of the words "they are of opinion that no referee's decision in a disputed case should be accepted as final," "that they are of opinion that the referees should be appointed by themselves." I think in that way we should render the resolution more complete, and I must say that I consider these few sentences unnecessary, "they are of opinion that no referee's decision," etc.

Mr. ALLEN: Perhaps the subject is scarcely ripe to appoint referees on the present occasion.

Mr. DUPRÉ: I most strongly object to the appointment of any referees whatsoever, if they are not to be tested by cross-examination.

The CHAIRMAN: Perhaps it would be well also to take cognizance of this fact, that we are not ourselves organized yet, and are hardly in a position to submit our body as a Court of Reference. That may come hereafter with better grace than on the present occasion.

Mr. HORSLEY: I think, Dr. Redwood, that if the statement or the analysis made by any chemist is doubted, and referred to somebody else, that analyst ought to be present at the time the experiments are made; because one analyst may make experiments very differently from another. I know, in my own case, that many persons cannot follow me.

The CHAIRMAN: That is a matter of detail, perhaps, which we might leave for the future.

Mr. WIGGIN: I merely wish to say in support, that I was induced to come seventy miles to a meeting of the Chemical Society with the expectation of hearing some chemical information from one of the principal authorities of Somerset House. I did so, but there was not, I believe, five minutes' talk in the whole two hours about chemistry. It was all microscopy, and ought not to have been there at all; and I went away with the impression that Somerset House was the last place to which the public analysts of this country should be sent as a Court of Reference, because, if time allowed, I could go into the question of tobacco and other things that are their specialties, and are not ours. The adulteration of food is a thing that has not been brought before them, and therefore they are not in an equal position with us in the matter. With respect to all the rest, I think if the committee were appointed, it would be in the interest of the whole body of analysts to rest content with whatever that committee might decide. Whether they appoint a small body of referees, or whatever they may choose to do, I, myself, am content to go with the whole body.

The motion was then put and carried unanimously.

The SECRETARY: The next proposition has been altered from the form in which it appeared on the printed paper to the following:—

"That the analysts present object to a compulsory examination of public analysts at South Kensington or elsewhere, as such examination would lead to the exclusion of chemists of experience, whose time is too valuable to be expended in such a manner, and to the appointments falling into the hands of young and inexperienced men; but they, at the same time, suggest that if a public analyst, hereafter appointed, is not an analyst who has been for some reasonable time in actual practice, or cannot in any other way prove his ability for the appointment, he should be liable to be called upon toproduce proof of having worked for two years under some public or other competent analyst."

The observations and objections to this are as follow:—Dr. Letheby objects to any examination by any educational establishment, but thinks it necessary that some clear evidence should be given of a candidate's competence. Mr. John Shea thinks any retrospective legislation objectionable; the present appointments must stand. Mr. Piesse says it is desirable to have a recognized analytical degree, without which no one should be allowed to practise. Mr. Rimmington asks what examining bodies and what examination? Dr. Campbell Brown objects to actual practice as not sufficient evidence in some cases as to fitness. Dr. Tripe suggests to make the alteration which we have made, that newly appointed is too strong—it should be hereafter appointed. Professor Bloxam said for "reasonable time" substitute "three years," and omit from "or cannot" down to "appointment." For "having passed," etc., he proposes to substitute "having worked for three years under a competent instructor."

Dr. TRIPE: I have much pleasure in proposing what you have just heard read. I felt that to attempt to exclude any analyst who has been appointed, would be an act which would not be recognized by any Government. In this country vested interests are very powerful, and I am fully persuaded that the vested interest in his appointment held by a public analyst is one which should not be lightly put aside. And I, therefore, proposed an alteration which has been adopted by the committee, namely, that the words "hereafter appointed" should be substituted for "newly appointed," inasmuch as the words "newly appointed" would include the whole of the analysts who have been appointed under the recent Act, because it is a comparatively new measure—that is to say, of not more than about twelve months' standing. If you were to say that is not a new appointment, you would have to fix what "newly appointed" meant, and therefore, under these circumstances, I thought that the words "hereafter appointed" should be substituted. I must say that I agree with you, Sir, that too much stress has been laid upon medical knowledge. Medical knowledge has really very little to do with the matter, save and except in the very few instances in which we have to certify whether or not the adulteration is injurious to health;

but I think that common sense would tell persons, in a great many instances, whether the adulterations are injurious to health or not. But of the necessity of skilled practical knowledge, there can be no doubt whatever; and those who have worked at the subject have found the extreme difficulty in working themselves up to the present state of knowledge. I would much rather, in fact, not have taken the appointment which was really thrust upon me than have undergone the trouble I have taken to make myself competent to carry out the matter. I cannot help thinking that if the public examination takes place, instead of the appointment falling into the hands of the young men, it might have the contrary effect; and that instead of there being a larger number of young men, then you would have a few men appointed to a large number of districts. Instead of one man holding three appointments, you would have half a dozen, ten, twelve, fourteen, or sixteen rolled into one; so that the guarantee of personal supervision of the work becomes less and less. I think that is another very strong reason indeed why this examination should not be insisted upon. With these very few words I propose the resolution which has been read.

Mr. Heisch: I have great pleasure in seconding the motion, with the addendum (which I am not sure that Dr. Tripe heard when he proposed his resolution), if it be the pleasure of this meeting, to cut out the words that he shall produce proof of having passed a chemical examination by some competent examining body.

Dr. Tripe: That was cut out by the Secretary, and the Secretary did not say the length of time which is proposed here. It is proposed here that it should be two years' work under some competent analyst. I therefore propose the words "two years" to be inserted in the blank that is in the resolution. I do not think it necessary to read the proposition, it having been read already.

Mr. Heisch: Under those circumstances, Sir, I will not take up your time by adding more, but simply second the motion. We were led to strike out these words by feeling that at the present moment there was no examining body on the subject of analysis, that would have our confidence, and as to legislating for the appointment of any future examining body, we thought this was not the time or it, and if a man has worked in the laboratory under a competent analyst for a reasonable length of time—say two years, if you like, it is a point I would leave entirely to the meeting, but I think two years is not too much to say—it would be a far better guarantee that he knew what he was about, especially if the analyst under whom he worked were to say that he had worked to good purpose, than any examination which could be conducted in the course of a reasonable time. I would say that no gentleman who had anything to do could be expected to give up his time to attend. I have great pleasure in seconding the resolution.

Mr. Bell: In speaking about the examining body of public analysts, I would suggest that if there is to be an examining body of public analysts the referees that are appointed by the public analysts should be the examining body in future cases. Supposing there are five public analysts appointed as a Court of Reference—that these gentlemen should be constituted to examine any future public analyst, because, as has been said, we ourselves must know more about food analyses, and so on, than they do at South Kensington; and therefore we should be better qualified to find out whether a man was fit for his post or not. I should almost suggest that "newly appointed" be kept in, because if it is really known that there are men who have got the appointment now who are not fit to hold it, then I should say that it had better be kept in, and I see no objection, if newly appointed, that they should be removed.

The Chairman: It would be rather an onerous thing.

Mr. Wanklyn: There are very strong reasons why we should not call in question the appointments that have hitherto been made, and I should propose to accept them all. If it should happen that persons have been appointed in some instances who are not able to do the work, let them learn to do it. But I think it would be exceedingly bad policy in us if we were to question the appointments that have been made. We have plenty of precedent of that kind, and those persons who know the history of the medical profession may recollect what the medical profession has done in similar instances, and we may take that as a precedent. We should pass resolutions only in regard to future appointments, and I think we should be wise in admitting that a great variety of proofs may be offered that a man can do his work. For instance, his having worked in the laboratory of competent analysts should stand for proof, and let his having passed a decent examination stand for proof. It would be very unwise to let South Kensington, for instance, have any preference over any other examination. We should acknowledge, I think, an examination at King's College, at the University College, at the University of Edinburgh, or anywhere over the country, as standing equally well with an examination at South Kensington. But I think we ought to insist in future on having proof of some, and it may be of various kinds, either of practical work in a laboratory, or else the passing of a proper examination. But I think we should be very unwise if we were to call in question any appointments that have been made hitherto. I believe a few, and only a few, have been improperly made, and I think we can afford to let these appointments stand.

Dr. Tripe: Allow me to suggest a slight alteration. It seems to me that these words, "under some competent analyst," are somewhat vague. Allow me to propose instead, "some public or other competent analyst;" you would then, to a certain extent, define what was meant by the word competent. I will therefore, with your permission, Sir, make the alteration.

Mr. Wentworth Scott: I beg permission to make a few remarks. Supposing that the word "hereafter" is inserted in the resolution, and the words "newly appointed" omitted, then I am entirely in its favour; and I must say I should protest strongly upon two points, namely, calling in question the appointments that have been made, or the abilities—be they good, bad, or indifferent—of the men holding those appointments for the time being. There would be a great many technical and social objections, in my opinion, to making them, in any shape or form, open to question. But I should also be inclined to insist upon practical work in a laboratory as the only safe means of enabling us to decide whether a man was competent to hold the appointment of public analyst for the future or not. If we were to accept a South Kensington examination, a King's College, or any other examination, under, as I may say, the examining bodies as we at present know them, we might have some very clever people pass as public analysts who would be very strong upon metallurgical substances, and we might have some remarkably hard-working young men pass as public analysts, who as regards manures would be exceedingly clever, and upon the other hand—and this is the most important objection in my opinion—that we might have a series of men pass who would do anything in the way of theories and black boards and windmills, but they would not know how to touch a loaf of bread or a pound of tea.

Mr. Horsley: I agree with what Mr. Wanklyn and Mr. Scott have said, that it ought to be prospective, and not of a retrospective character.

The Chairman: Well, then, the proposition stands as it is, and I shall be glad, now, to take your decision in reference to it.

The motion was then put and carried.

The Secretary: The next proposition is slightly altered from the draft:—

"That the analysts present repudiate most emphatically the reported assertion of Dr. Voelcker (or a certain agricultural chemist), that 'there are not a dozen competent analysts in the kingdom,' which assertion is referred to in the report of the Committee, and can only characterize this statement as (to quote Dr. Voelcker's own language) very flippant and unwarrantable."

The quotation from the report of the Committee is, "One eminent chemist stated he did not think more than a dozen of such men existed." And the remarks we have received from different writers are as follow: Dr. Letheby says, "I think it very imprudent to make any reference whatsoever to Dr. Voelcker's statement." Mr. John Shea "proposes to omit the words after kingdom." Mr. Baker: "Quite unnecessary to notice." Mr. C. H. Piesse adds, "And we are surprised that the Committee should receive Voelcker's evidence, passing over so many analysts capable of giving useful evidence founded on experience." Mr. J. Young thinks it might be omitted as not being worth the honour of such a notice. Professor Bloxam: "Not dignified to notice Voelcker." Mr. Scott: "Not worth noticing." Mr. Rimmington: "Quite right, but too mild." Mr. Fairley: "Not wise to notice Voelcker's statement, unless facts are given in support of it."

Mr. ALLEN: In rising to propose this motion, which you see we are somewhat divided upon, I think it is only fair to say that we should not have considered it worth while noticing the opinion of Dr. Voelcker, or any other man who might so express himself, if it had not been that the Adulteration Committee have evidently given credence to it more or less, and have placed considerable confidence in his statement, and they laid stress upon it, inasmuch as they actually refer to it in their report. Now, when they have omitted noticing a great deal of evidence of an opposite character, given by Dr. Hassall and others, it is a very curious thing that they should have hit upon that, if it were not that they really believed it. It is, therefore, highly desirable that we should do everything in our power to disabuse the minds of the Committee and the public on this particular point, and when I see before me some three or four dozen analysts, representing the towns of the United Kingdom, and we are told by that very eminent agricultural chemist that there are not a dozen competent analysts in the kingdom, it is quite certain that there are some three out of every four of us here not competent, if what he says is true. And I am quite sure that there is no one who would like to come forward and say that he was not competent. For my own part, I have no doubt that Dr. Voelcker's assertion is inaccurate. Dr. Voelcker has said that he would not like to be a food analyst, and be classed with them, because there were some who did not stand very high in their profession. I am not an agricultural chemist, and I should object to be an agricultural chemist, because I might be classed with Dr. Voelcker. On this account I think it only right that we should express our opinions on the subject, but I would recommend this form, and leave out the name.

The CHAIRMAN: Our proceedings might be simplified by leaving out the name, and saying that the analysts present repudiate most emphatically the assertion that there are not a dozen competent analysts in the kingdom, which assertion is referred to in the report of the Committee.

Mr. ALLEN: I have no doubt the man whom the cap fits will know whom it is intended for.

Mr. BLYTH: I rise to ask the gentleman who proposed it to withdraw it. I believe it is perfectly unwarrantable that such an assertion should be brought before gentlemen from all parts of the United Kingdom. I did not understand that we were met to talk about or speak against any particular person. The assertion itself is not even fixed upon Dr. Voelcker. He has not even been mentioned by name, and though I am not a friend of his, I think it would be a most undignified proceeding for us to say anything about it, and I ask the gentleman who moved it simply to withdraw it, so as to stop all discussion on the matter. It is very likely mere conversational utterance, and if we pass any resolution upon it, it would be giving his assertion a dignity which that particular chemist's professional position in no degree warrants.

Mr. ALLEN: It was no mere conversational utterance, but was given in evidence before the Adulteration Committee.

Dr. DUPRÉ: I may say I was present on the occasion at the Committee, and I heard him say it, and it was no mere conversational utterance. If a man goes out of his way and throws dirt, so to speak, upon a public body, which fortunately, as it happens, does not deserve it, I believe we are not at all going out of the way, nor are we doing anything undignified, in alluding to it. I am of opinion that we should leave his name in. I know Dr. Voelcker personally, and I respect him; but I think he was perfectly unwarranted in making such a statement that there are not a dozen competent analysts in the kingdom, and that the analysts are in the habit of giving their evidence in a flippant manner.

Dr. TRIPE: Having discussed this matter and given our opinions expression, through the press, to the world, will not the object of the proposition be attained, and therefore would it not be better to withdraw it?

Mr. ALLEN: I am willing to withdraw it under these circumstances. We have expressed our opinions, and no doubt that is all that is necessary.

The CHAIRMAN: I think, myself, that that is the wisest course.

The motion was then withdrawn.

The SECRETARY: The next proposition is—

"That the analysts present are of opinion that the report of the Committee is defective, inasmuch as it does not state what does and what does not constitute adulteration, and this omission will increase rather than diminish the liability to difference of opinion between analysts."

Dr. Hassall says, "The resolution is too mild. The re-report is imperfect, partial, utterly erroneous in many of its statements, and if its recommendations were carried out, the interests of the public would be greatly prejudiced thereby." Mr. Piesse thinks it is "defective because no reference is made to examination of drugs." Mr. Young suggests "better leave it for the amended Act." Professor Bloxam: "No definition possible; should be a schedule." Mr. Scott: "Unnecessary, as to his knowledge it will be embodied in the new bill." Mr. E. H. Moore: "A definite schedule might be composed, based on actual work." Dr. Tripe: "Should be a list of synonyms; for instance, that laudanum is tincture of opium, etc., and that all medicines or drugs should be equal to the standard of purity fixed by the Pharmacopœia."

Mr. WANKLYN: I rise to move the resolution that has been read. The difficulty in the Act depends upon the definition of adulteration. If the word adulteration were to be received in its literal sense, it would not cover the purposes of the Act at all, for the spirit of the Act, and the way in which the Act is being interpreted by the judges, is one thing, and the literal interpretation of the Act is another. In order to make this Act work as it is desirable that it should be made to work, and the judges are endeavouring to make it work, we require to deal with cases in which an article of commerce has been rendered less valuable, not by the putting in of things extraneous to them, but by leaving something out that they ought to contain, and clearly taking the word adulteration in its literal sense, it does not cover that at all. I propose that we should define the word adulteration ourselves, or rather define a word that should have been in the Act, instead of the word adulteration.

The CHAIRMAN: You would not attempt that now, Mr. Wanklyn.

Mr. WANKLYN: That would be necessary for us to do, and I move that the report of the Committee is defective because it has failed to do that which it is imperatively necessary to do.

Dr. ROGERS: I have very much pleasure in seconding this motion. It appears to me that this is a fundamental defect, and I am strongly of opinion that the omission should be supplied. If it remains unsupplied, it will increase the difficulties in the working of the Act very considerably, and I fully agree with the resolution that this omission will increase rather than diminish the liability to difference of opinion between analysts. Mr. Wanklyn has touched upon the desirability of providing for the abstraction of substances rather than the addition, or as well as the addition, and I think that ought to be considered too, and that at some future time we should give a definition of what is and what is not an adulteration.

The CHAIRMAN: I may be allowed to state that there will be a motion further on referring to that particular subject. The secretaries have received communications from 50 analysts making various suggestions, and it will be proposed to have the subject submitted to a committee with a view to arriving at some definite proposal.

Dr. TRIPE: I think it would be necessary that a list of synonyms should be referred to the Committee, because I have been defeated in proceedings which I have taken in consequence of things having been obtained, such as precipitated sulphur having been obtained as milk of sulphur; there is no such thing as a standard milk of sulphur, and consequently we could not go on.

Mr. WENTWORTH SCOTT: Mr. Wanklyn has very properly pointed out both the defect in the report of the Committee, and also the difficulty which appears to exist in some people's minds in relation to what does and what does not constitute adulteration; and he pointed out an extraneous substance being added to articles sold, as well as some valuable constituent being abstracted. However, I think that is no real difficulty. The same thing was brought before me in a certain district for which I act, and I was pretty well told that in relation to such a common thing as skim milk, however much cream was abstracted, I could not get a conviction on that point.

The CHAIRMAN: Will you allow me to suggest that that will more properly come by-and-by. You have heard the motion read.

Mr. WENTWORTH SCOTT: I abide your decision.

The motion was then put and carried.

The SECRETARY: The next proposition is—

"That the analysts present are of opinion that the facing of tea is essentially an adulteration, and as such to be opposed; but they further think that if faced green tea is to be allowed at all (as recommended by the Committee), the amended Act should specify a distinct limit as to the per-centage of facing to be allowed, since the wording of the report leaves it open to the analyst to determine what is fairly faced green tea, and will thereby increase the difference of opinion on certain samples."

The opinions are: Dr. Wanklyn says, "ash in tea not to exceed 7 per cent." Mr. A. J. M. Edger, "faced tea should not be allowed at all." Dr. Hassall, "if facing be allowed in any case, it must be so in all." Mr. Baker, substantially the same as Mr. Edger. Mr. Young, "not exceeding 2 per cent." Mr. E. W. T. Jones, "facing should be condemned." Mr. Scott, Mr. Bancroft, Mr. Davies, the same opinion. Dr. Campbell Brown, "no such thing as fairly faced green tea,—might as well talk of fairly coppered pickles." Mr. Jarmain proposes for "if faced tea is to be allowed at all," to substitute "the sale of faced tea should be prohibited, but if allowed at all," etc.

Mr. ESTCOURT: I will call the attention of the gentlemen to the word "green" in this motion, between faced and tea, since without that, it would legalize the facing of black tea. If you read it carefully, you will see it would have that effect. There can be no question about it.

The SECRETARY: Would you not include the word "green?" That is the only facing that would be permitted. Facing black tea would be an adulteration.

Dr. TRIPE: Facing black tea I should consider an adulteration now, because that is passing it for a thing which it is not.

Mr. ALLEN: Would you say colouring instead of facing?

Mr. ESTCOURT: In their report under the head of facing they imply colouring as well. I have great pleasure in proposing the resolution that has been read with that change.

The CHAIRMAN: Is there any gentleman prepared to second this resolution relating to the facing of tea?

Mr. HEISCH: I rise with great pleasure to second this motion, and in the abstract I agree with those who say tea ought not to be faced at all, but I do not think, speaking as a practical man, that we have the slightest chance of carrying that for a good many years, and therefore I concur in this resolution which says "that if faced tea is to be sold at all." I put it as a thing that we only admit because it is almost impossible at present to prevent it, and with that reservation I have great pleasure in seconding the resolution.

Mr. WENTWORTH SCOTT: Perhaps it would be as well, Sir, as I am bound to oppose that resolution almost *in toto*, if I propose an amendment of mine before any remarks are made upon the subject. I am quite of the opinion of both the proposer and seconder in the abstract sense, but I should object decidedly to anything like a public confession of weakness on our part like that suggested by Mr. Heisch. I do not think a line could be drawn between a little facing and a little more facing, which you could go on increasing indefinitely. I beg to propose an amendment. "That in the opinion of this meeting no dyed, faced, or otherwise adulterated tea should be allowed to be sold after a certain reasonable period has elapsed for the exhaustion of present stocks, as the legalization of one species of adulteration would probably open the door to other and more serious malpractices."

Mr. BURGE: I have great pleasure in seconding the amendment.

Dr. TRIPE: I am somewhat unwilling to speak again, but as I think one of the most important principles we have to discuss is whether or not we shall give our countenance to what is really an adulteration—I care not what is expedient—our duty is to do not what is expedient, but what is right; and I shall, therefore, support the amendment strongly, because I do not think it is right or just in us in the slightest degree to countenance what is undoubtedly an abomination. As far as I myself am concerned, nearly all the samples of tea that I have had faced or coloured have been black tea coloured green. Now, that is an undoubted adulteration. If you allow the facing of green so as to make green more green, why should you object to the facing or colouring of black tea to make black more black, or to make black tea look like green? Surely it is passing off on the public, and supporting it by our authority, that such things may be done. I protest against any such thing, and therefore it is I most emphatically support the amendment.

Mr. WANKLYN: In respect to the observations made on the facing of tea, I would wish to remark that it is not clear that the facing of tea is an adulteration.

Dr. TRIPE: It is a legal adulteration.

Mr. WANKLYN: It is not within the interpretation put upon the Act; it does not seem to be. If by facing tea you were to render it poisonous, then the tea would be adulterated in the meaning of the Act. If, by facing the tea, you were to make it so that a given weight of the tea would not yield you as much of the beverage, then that would be an adulteration according to the meaning of the Act. But in the mere fact of facing, I do not see any adulteration at all. Let us take a parallel case. There is the well-known case of cheese. Cheese, as we know, is generally faced with annato, and yet we could not hold that the colouring of cheese is an adulteration of cheese. And suppose the Food Act were to extend throughout commerce so as to apply to clothes, we could not regard the dyeing of clothes as an adulteration of them. Aud the facing of tea I should regard much in the same light as I should any article of commerce. It may be done for the purpose of deception. When it is so practised, let the person be prosecuted for deception, but not for facing of any teas. I think we should make a great mistake if we were to stretch the Act too far, and make it apply so as to fetter commerce at all, without gaining any benefit, and I do not think we should object to the facing of tea, unless the tea be poisoned, or unless the tea be rendered sensibly weaker by it. In the answer that I returned, I proposed that we should require that the ash of tea should not exceed 7 per cent.; that will be equivalent to allowing something like 2 per cent. for accidental dust and for facing, and I think it would be reasonable to allow that in a substance so variable as tea. It would be unwise to insist upon a stricter standard.

Mr. Jones: I am one to support the amendment of Mr. Scott very staunchly, for I think that if the public analysts recognize the facing of tea, they ought also to recognize slight watering of milk, or slight skimming of milk, or any other slight adulteration. I think that we, as a body of public analysts, should decidedly set our faces against anything that could be termed an adulteration to any extent.

Mr. Wiggin: I think with respect to the assertion of Mr. Wanklyn, about its being poisonous or injurious to health, the mere fact of adding turmeric, Cayenne pepper, and flour to mustard is an adulteration, and therefore I think that definition is quite beyond the question. It is an adulteration of the article, and we ought to be the body above all others that should stand up for purity.

Dr. Dupré: I am very strongly in favour of the amendment. I strongly object to analysts as a body recognizing any kind of adulteration whatever; and even supposing we have not at present the power of carrying such an amendment of the Act, still we give to the public what we consider to be a standard; and I think the standard should be the highest possible that we can get. With regard to Mr. Wanklyn's illustration, I should think that if any person sold me cotton clothes that looked like wool, because the cotton was dyed, I should not be satisfied; or if I buy cotton which is so skilfully manipulated that it looks like silk, I should object to it. We have heard of the poor Indians buying coats that when washed all ran away in facing.

Dr. Stevenson: With regard to the facing of tea, if it is used for the purpose of concealing what the tea really is, or of making the purchaser think that it is one thing when it is another, I should sharply deprecate such facing of the tea; but at the same time I believe that there are many green teas of high quality, which are not faced for the purpose either of adding to their weight or bulk, or of increasing their value; but we know that people have a fancy for certain appearances on the tea which they may have been accustomed to associate with that kind of tea, and I think we have no chance whatever of overcoming that prejudice for some years to come. Any admission that the facing of tea would be permitted under the Act would not be binding, I apprehend, for any great number of years. And gradually it would come to pass that unfaced tea would be more appreciated than faced tea. I think that this meeting should not insist upon what they have no chance whatever of carrying, for the Adulteration Committee have it in their evidence, and they have strong evidence to show, that the facing of tea is not in all instances a practical adulteration, and that, in a great many cases, it is not done with such an object. I think it is far better for us—whilst not admitting that faced tea ought to be allowed, and whilst we do not admit that the opinion of the Committee is right that faced tea should be allowed—to aim at what is a practical rather than at what we consider would be the highest standard. I think we should aim at what is possible rather than at a theoretical standard, and that for the present we should be satisfied with passing the original motion, which does not commit us to any opinion that facing tea is admissible; but it recognizes the fact that the Committee have had sufficient evidence to alter the law so as to admit the facing of tea. We should do all we can to stop this facing of tea from going beyond a certain point.

Mr. Allen: I must say that I agree with Mr. Wanklyn and others who have said that we must not consider the facing of tea an adulteration in every case. We must distinguish very carefully between ordinary facing, and the case of black tea which is made to look green by being painted green, and which, therefore, gives the consumer the idea of higher strength and superior price, and should be called an adulteration. But when olive green tea has been changed to a bright green, that should not be considered an adulteration, because it is not done for that purpose, but to suit the public, and is not the passing off an inferior quality. The public like bright yellow mustard, and they like brown vinegar instead of white, and it is a pure fancy on their part, and as long as the fancy for one colour is unobjectionable, and as long as there is no cheating over it, in the sense of making an article appear of superior value than that which it really is, I do not think that we have any right to oppose it.

The Chairman: I think, perhaps, gentlemen, that the views of some of those who do not consider this proposition quite stringent enough would be met by a little modification in the form, which the mover of it is prepared and disposed to make; and if you will allow Mr. Estcourt, I think he will submit to you a slight alteration, which, I think, will meet the views of all. I confess that I am not prepared to go to the extent of this proposal. It would be going too far, and it would commit us to a principle which we should find it impossible to carry out. There are a great many cases where it would be impossible to carry it out. Mr. Allen has referred to the case of vinegar. There are many other cases where a slight colouration is practised, which does not exert any influence at all upon the quality of the article, but it has this good effect, that it enables the dealer to equalize the general appearance of a great number of samples, which in regard to their intrinsic properties and value, resemble each other, but which may have some slight difference to the eye, and I do not think that the use of a slight amount of colouring matter to meet the prejudices in cases of that description can be objected to, where it can be shown that it is not at all injurious, and does not affect the pocket, and does not increase the quantity at all. We should be very careful how we attempt to draw the line too stringently. I think that it would tend greatly to depreciate the supposed value of the application of this law on the part of the public, if we were proceeding upon what might be considered to be very slight grounds of that description. But, however, the question now is as to the modification of the original motion.

Mr. Estcourt: As the mover of the original motion I may perhaps be allowed to make this alteration. There is no question amongst us, I believe, that there is a great objection to the adulteration of tea, but the resolution went simply to the point of permitting it in any quantity. I propose this modification, therefore, to meet the views of Mr. Scott, and those who support him. After the word "samples" add "and they are also of opinion that faced or coloured teas should be deemed adulterated when the ash exceeds 7 per cent."

Dr. Tripe: If you will not object to these words being put in, I think we might then come to an agreement. After the words "as recommended by the committee," insert, "but what this meeting objects to." If you protest here at this meeting that you object to faced tea altogether, I have no objection to withdraw my support of the amendment. And perhaps you will consent to take the per cent. of ash as six and a half instead of seven. The half per cent. may not seem much, but it really makes a great deal of difference.

The Secretary: I would suggest that the resolution should commence, "That the analysts present are of opinion that the facing of tea is essentially an adulteration, and, as such, ought to be opposed ; but they are of opinion that if faced tea is to be allowed at all (as recommended by the Committee)," and so on.

Mr. Estcourt : That would meet the views which have been expressed, as it does not affect the question of the ash, which would be an after question.

The Chairman : Will that meet your views, Mr. Scott ?

Mr. Wentworth Scott : Hardly so. When the discussion has ceased, I will say a few words, with your permission.

The Chairman : Mr. Scott, as the mover of the amendment, did not make any observations in moving it, and we will therefore hear what his views are.

Mr. Scott : It is this. The last speaker has, I think, unconsciously entered upon what I may call the keystone of a very large difficulty in relation to the resolution or the amendment in question. There are some propositions made in relation to a legalized adulteration—I can call it nothing less—of 7 per cent. My friend on my right, Dr. Tripe, suggested $6\frac{1}{2}$ or 6 per cent. I have not the slightest doubt that if you ask the opinion of every gentlemen present in the room, and if you go beyond this room, and ask the opinion of all the other public analysts in the country, you would get every possible modification that is known to arithmetic, from the smallest decimal fraction upwards, and therefore I do not think there would be the slightest chance of our agreeing as a body to 6, or $6\frac{1}{4}$, or $6\frac{1}{2}$, or 7, or any other particular amount being allowed.

The Chairman : You are aware, Mr. Scott, that 7 per cent. refers to the total ash of the tea, not the ash that represents the facing.

Mr. Wentworth Scott : Perfectly. That allows for 1 or 2 per cent. of adulteration, but I would put it first, that I think it is bad on principle, so to speak, to give the exhibition to the British public of a body of analysts going about, as it were, on uncertain footsteps and with bated breath, saying, "Well, we will accept the recommendation for adulteration to this extent. We will allow a little skim milk here and a little copper there, if you do not do us much harm." I must protest against a compromise of this sort, as being against the dignity of this Association, if it is to be an Association at all. And I may say, from facts in my possession, that that view is very much shared outside this room. I may say, with regard to the facing of tea not being injurious, that it is very difficult to draw the line between where it is so and where it is not. Three weeks ago a poor woman called upon me, and brought a sample of green tea. She said, "I would like you, Sir, if you don't mind, to look at this. I think it has done my daughter some harm." Her daughter was suffering from throat disease. I found that tea rather largely faced. I said to the woman, "You say your daughter expectorates a good deal ; let me have some of the expectoration." She brought me some, and a microscopical examination showed me little sharp particles of mica, which must have been very injurious, and especially to a person suffering under that particular kind of throat disease. Therefore, I am of opinion that we ought to lay down a hard-and-fast line, and say that we cannot and do not permit adulteration in the shape of faced tea. Whatever may be our personal opinion upon the subject, it is surely within the compass of our dignity and quite within the compass of our knowledge as analysts. In writing our certificates—I am sure I speak now for every gentleman in the room—none of us would countenance a mere trumpery prosecution upon one per cent., or one and a half per cent., or anything of the decimal fraction order. I, for one, would not, and never have, and I think it may be safely left to the analysts' good sense, and to their general and official dignity, to avoid injury of that kind to vendors, and also to their own reputation. With the utmost respect for all the remarks that have been made, with many of which I cordially agree, I think it would be more satisfactory, Sir, to allow the amendment to rest as it is.

Dr. Dupré : Perhaps, as I made some remarks on the resolution, I may say a few words. It would be very desirous that if possible we should be unanimous, and perhaps we might be so if we altered the resolution in some way like this : "That the analysts present are of opinion that if faced tea is to be allowed at all, the facing should not, at all events, be permitted for the purpose of converting one quality of tea into another."

Dr. Tripe : You cannot take that amendment until the other is disposed of.

The Chairman : I think we cannot. Then, gentlemen, I will put the amendemnt.

There appeared for the amendment, 9 ; against it, 12.

The Chairman : The amendment is lost. Then, shall I now put the original motion in its original form? It appears to me that really Mr. Estcourt's modified proposition comes very nearly to what Dr. Dupré has said.

The Secretary having again read the motion with the modification proposed, it was carried by 11 to 6.

The Secretary : The next proposition is—

"That tea being an article subject to duty, the analysts now present see no objection to its being examined in bond, in accordance with the recommendation of the Committee."

Not one of the 55 replies takes any notice of that.

Dr. Stevenson : I have great pleasure in proposing this resolution, and hope it will be carried without much discussion, to show the public and the House of Commons, too, that we, as public analysts, have no desire to assume any work that can fairly be carried out by any other body. If tea can be subjected to examination before it has passed into the hands of the public and the analysts, a great benefit would be conferred upon the consumers, and much expense would be saved to the country. The analysts would not desire to examine tea if it could be fairly examined elsewhere. At the same time I must point out that such a resolution would not prevent the analyst examining tea if any adulteration should be practised in this country, if it fell into the hands of the analyst.

Mr. Wentworth Scott : I can second this motion, because the mover of it has made use of almost the very words which I have inserted in my copy, that the examination in bond should form no bar to conviction, should the tea afterwards be found to be adulterated. The object of this is to meet the case of some grocer or lawyer coming down to the court with a piece of blue paper and saying, "Oh, here is the Government certificate; you cannot go into the case."

The Chairman : I confess it seems to me unnecessary to make such an addition, but, of course, it is open to you.

Dr. Tripe : As a matter of form I will second Dr. Stevenson's motion.

The Secretary : Do you wish to move an amendment, Mr. Scott?

Mr. Wentworth Scott : I will do so, or leave it in the hands of the meeting. I have no wish to press it.

The motion was then put and carried unanimously.

The Secretary : The next proposition is—

"That, while agreeing with the general recommendation of the Committee that mixtures should be labelled prominently, instead of a mere verbal declaration of the admixture being made, we consider that the per-centage of the ingredient under the name of which the mixture is sold, should be stated *on the label,* and any excess over the stated per-centage of diluent should be deemed an adulteration."

Dr. Corfield thinks that a verbal declaration should be given, even if the mixture is declared in print, as purchasers ought not to be put to the trouble of reading the labels. Mr. W. W. Stoddart asks, "Is not this too strong?" Dr. Hassall entirely differs. There should be both a written and a verbal declaration, and mixtures should be sold, not under the name of the principal constituent, as "coffee" or "mustard," but as "coffee mixture," etc. Mr. Piesse would add, "and if the actual amount of added matter be in larger proportion than stated on the label, the quantity in excess shall be deemed an adulteration." Mr. Young says "impracticable." Mr. Rimmington would insert the word "prominently" before "labelled." Mr. Moore says, "This is a necessity if the Act is not to be evaded." Professor Heaton doubts the wisdom of this.

Mr. E. W. T. Jones: In proposing this resolution I do so with very great pleasure, as I think it is of the highest importance that all articles should be distinctly and prominently labelled. There was a case of mine in the country the other day, where there was a serious adulteration of tea. There was no doubt about the adulteration, but the man happened to say, "Well, we believe this tea is pure, but we do not guarantee it to be absolutely genuine." The magistrate held that he had declared that that was an adulterated tea; the consequence was, the prosecution fell through. I really do think that all articles sold should be distinctly labelled, and in such a manner as to clearly represent what they are sold for.

Mr. Rimmington: I shall be glad to second this motion. I have inserted the word "prominently" in my copy, that is, that any notice that is put on the label should be prominently placed on the package—not stuck on one side or on the back of it, or anything of the sort, but that it should be boldly labelled what it is.

Mr. Estcourt: I would propose that the wording of the label should be of a larger type than the other printing of the package.

The Chairman: Do not you think that that is a matter of detail that would come into consideration afterwards in framing the Act? It would be wise to confine ourselves chiefly to broad matters of principle on the present occasion.

Mr. Wentworth Scott: I have very great pleasure in supporting the proposition which has been moved by Mr. Jones, and I have only to suggest that the word "approximate" should be expunged, and the word "minimum" be substituted therefor. And to save time I may say that Mr. Jones has already accepted that alteration. If you use the word "approximate," it opens the door to a lot of forensic waste of time as to what is and what is not an approximate per-centage. If we make it definite by using the word "minimum," it will save that.

The Secretary: "Strike out the word approximate."

Dr. Corfield: I should like to say, in the first place, that I think it necessary to insert the word "prominently," as it happened within my own knowledge that a mixture was sold and was labelled, but the statement that it was a mixture was put inside of the package, so that it was perfectly impossible for the purchaser to see it unless he could see it through the paper. So the word prominently is necessary on that account. The next thing that I should like to say is that I think it would be very much better if the motion ran as follows—"that mixtures should be labelled, and a verbal declaration of the admixture made." I say this because there are a great many persons who buy things and who cannot read, and I do not see why a person who cannot read should not have the article he pays for. There are a great many persons, too, who cannot speak the English language, and who cannot read it either, and there are a great many other persons who do not want the trouble to read all through a label when they buy an article, even when they can read.

Dr. Dupré: There is one difficulty in regard to a verbal declaration. The seller would have to state: "This contains 25," or "30," or "40," or "50 per cent." Suppose a child should be the purchaser, how long will he remember what was told him as to its contents? There will be no end of disputes. The child will say, perhaps, "He told me it was 48 per cent.," and the man will say, "No, I told him 50 per cent."

Mr. Heisch: But the verbal declaration is in addition to the label, not in substitution for it.

Dr. Corfield: I propose both, certainly, that when a mixture is sold it should be labelled, and at the same time a declaration should be made.

Mr. Allen: I think it is quite sufficient if it is expressed on the label prominently. At busy times, such as Saturday nights, it necessitates a great deal of trouble that everybody should be told, "This is a mixture." It is really quite the exception for a person not to be able to read nowadays. It is sufficient, I think, if you put it on the label.

Mr. Rimmington: I have a strong objection to this verbal declaration. A person might go into a shop on a Saturday night, and ask for coffee and get chicory and coffee, and the declaration may be made and the person never hear it. Besides, there are a great many difficulties in the way of carrying it out.

The Chairman: I will put the motion, and you will please understand, first, that the word "prominently" is inserted before labelled, and secondly that the word "approximate" is struck out.

The motion was then put to the meeting and carried unanimously.

Mr. Wiggin: I understand the proposed resolutions 9 and 10 are to be postponed until the meaning of "adulteration" is defined. I understood some time ago that the committee were going into the question of what is adulteration. I know that upon the discussion of these resolutions we shall have a lot of conversation and speechifying as to what is and what is not adulteration, and I humbly submit whether it is not better to settle the meaning of "adulteration" first.

The Secretary: I will read those resolutions, which are as follow:—

"That there are certain classes of mixtures, for instance, burnt corn and chicory in cocoa, which should be expressly prohibited.

"That while agreeing with the Committee's recommendation to make the sale of skim milk for new milk a punishable offence, we consider it essential that a minimum per-centage of 'butter fat' should be fixed by the Act in milk sold as new milk, and we suggest $2\frac{1}{2}$ per cent. as the minimum, and we further consider that a minimum per-centage of 'milk solids not fat' in milk should be fixed by the Act, and we suggest 9 per cent. as the minimum; the proportion by weight in each case being calculated in reference to 100 volumes of the milk."

The opinions on these are, "Dr. Letheby would not interfere with any kind of adulteration whatever, provided it is not unwholesome, and is declared by label on the article. Mr. Wanklyn before the words "sulphuric acid" would insert "more than a certain proportion of." Dr. Hassall thinks it unnecessary. To prohibit sulphuric acid you must repeal an Act of Parliament. Mr. Collins gives substantially the same opinion as Dr. Hassall. Mr. Young thinks it would necessitate repeal without inconveniencing any one. Professor Bloxam inquires, "Is not sulphuric acid necessary for the prevention of 'mothering' in vinegar?" Mr. Bancroft "would prohibit salt in beer." The ninth resolution is addressed simply to the question whether there should be a prohibitory schedule. It does not specify a single thing except by way of example.

Dr. Tripe: I will second the proposal to defer propositions 9 and 10.

Mr. Wiggin: I quite agree with all that has been said.

The Chairman: Allow me first to gather the sense of the meeting on the proposition made here as to whether we should like these two resolutions to stand over until we have disposed of the question of what adulteration is.

Mr. WIGGIN: I am quite agreeable to let the matter stand over.

The CHAIRMAN: This being assented to, I think then these two resolutions had better stand over for the present.

The SECRETARY: The next is—

"That we approve of the recommendation of the Committee that inspectors should be 'empowered to *take* samples upon tendering full payment.'"

And the written observations are, Mr. Piesse desires to add, "if the shopkeepers refuse to serve them with any article exposed for sale." Mr. Young asks, "Is it practicable?" Mr. Scott would insert after "inspectors" "either personally or by deputy."

Mr. BLYTH: I beg to propose the resolution with the addition, "that purchasers of samples should be a uniform body, and that their action in each town and district should be as equal as possible."

Mr. WENTWORTH SCOTT: This resolution has been placed in my hands, and your observations will come as well if you second the proposal.

Mr. BLYTH was about to make some remark, when

Mr. WENTWORTH SCOTT said: May I interrupt? I have very great pleasure in moving the eleventh resolution, with the very slight alteration which the Secretary has read. Perhaps I am peculiarly sensitive as to the great need for a resolution of that character, inasmuch as, within six months, seven assaults have been made upon one of my inspectors or deputies during the progress of his duties in purchasing samples; and a variety of amusing and, I may say, uncomfortable incidents have occurred. A packet of pepper was dropped on the inspector in one case, and in many cases samples have been lost. In a few instances fines have been inflicted for assaults connected with such acts. If it were made legal and generally recognized that inspectors had a right to take samples, either by themselves or by their properly appointed deputy, it would be taken as a matter of course as a legal right, and these assault cases would no longer be heard of. I have very great pleasure in moving the eleventh resolution.

Mr. E. W. T. JONES: I beg to second that motion.

Mr. BLYTH: Then what I propose would be really an amendment: "That it is desirable that the purchasers of samples should be a uniform body, and that their action in each town and district should be as uniform as possible." I propose this in consequence of what I know occurs in my own counties. I do not know whether the analysts of the metropolis will bear me out exactly, but I think that those who are country analysts, and do their work in the country, will bear me out. The Act says that the inspectors of samples should be either the inspectors of weights and measures, the inspectors of markets, or the inspectors of nuisances; so that there are three bodies to choose from, and, as a fact, local bodies often choose the least capable men of the three. The inspectors of nuisances are often connected with trade. One or two inspectors of nuisances in the county of Devon, who are empowered to buy samples and send them for analysis, are sellers of milk. They sell the very article that is to be examined. In counties there should be a uniform body appointed to obtain samples. I myself believe that superintendents of police would be the best; at all events, they have been found the best in the county of Somerset. That system works very well indeed there. They are a uniform body, and they are connected with no trade whatever. But I leave the question open. I do not propose that we should suggest that the superintendents of police, or anybody else, or any particular body, should be selected by the Government, but that some uniform body should be selected. It should not be left to the three classes of inspectors mentioned, unless they can be appointed uniformly all over the country. I am quite willing that there should be inspectors of weights and measures, or inspectors of markets, or inspectors of nuisances, if they are the same all over the country; but where the inspectors of samples are derived from different classes, you get a large excess of action in one part of the country, and none in another. In some parts of the county of Devon there is hardly any inspection, while another part is inspected too rigidly.

Mr. WIGGIN: You ought to have some power over the body who is to appoint.

No one seconding the amendment, the motion was then put, and carried unanimously.

The SECRETARY: The twelfth proposition is—

"That the proposal to leave a portion of the sample with the vendor is objectionable, and will at once open the way for fraud, because inspectors are not, as a rule, able to seal and secure a sample in such a way as to render it impossible to tamper with it. We consider that giving the vendor permission either to accompany the inspector to the analyst or to seal the sample himself, will entirely meet the necessities of the case, and afford the vendor all necessary protection."

Mr. YOUNG says, "the inspectors should be able to seal the parcels. The vendors accompanying inspectors is out of the question." Professor Bloxam recommends that the inspector should seal two samples, one to be delivered to the analyst, and the other to be deposited at the inspector's office for reference. Mr. Morgan would prefer the vendor's seal to his presence. Professor Heaton says, "I think that a duplicate sample should always be taken, sealed, and carried away by the inspector. It could then, by the desire of the tradesman, be handed direct to his analyst. Mr. Fairley thinks that no sample should weigh less than four ounces, and the inspector should secure eight ounces.

Mr. ALLEN: I have great pleasure in moving this resolution. I think we ought to use our very utmost endeavours to prevent ourselves being thrown on the mercies of the inspectors. The men themselves are sometimes men of a very low class of life, to whom a £10 note is a very great object; and if they are to be allowed to lend their seal for a few minutes to the vendor, the vendor might replace an adulterated article by a genuine. In that way he could upset your case and damage your reputation. We ought to strive our very utmost to prevent a sealed or authenticated sample being left with the vendor. If the vendor doubts the honesty of the inspector, he can accompany him to the analyst, and put any seal or mark he likes upon the sample, which the analyst ought to mention on his certificate, but on every ground I object to the inspector sealing and leaving an authenticated sample with the vendor.

Mr. BURGE: I have very great pleasure in seconding this motion. I think it is of very great importance that the sample should be sealed by the analyst, and I think that can only be done in the way which it is now, by being sealed in the presence of the analyst.

Dr. DUPRÉ: I am very greatly in favour of the resolution, but I think it would be a pity if we as analysts should make it appear as if we doubted our inspectors. The person whom we have to doubt is the dealer who adulterates, because the man who has already adulterated is just the person who would be willing to tamper with the sample. To pass this resolution on the ground that our inspectors might be bribed, I think would be a very great pity—if it were generally known or to become public that we as analysts have that notion.

Mr. BURGE: I beg to say that in seconding the motion I had no idea of that kind.

Dr. DUPRÉ: But Mr. Allen's remarks will no doubt be published amongst the rest, and it would be a pity if they were to pass without being noticed.

Mr. WIGGIN: If the order of the Act of Parliament were fully carried out it would prevent this.

Mr. WENTWORTH SCOTT: I, for one, should regret extremely that anything should go forth from this meeting to cast a slur upon any particular inspector or body of men. I happen to be particularly fortunate in my inspectors, and therefore I may be in a better position than others; but I should be sorry for any expression of the kind which has been described to go forth.

The CHAIRMAN: It would be a pity if any imputation of that sort went forth.

Mr. ALLEN: I was not speaking on that point at all.

The motion was then put and carried unanimously.

The SECRETARY: The next proposition is—

"That we consider that any mode of delivery of samples to the analyst other than a personal delivery is objectionable."

Very considerable numbers who have sent their opinions have been against it, and almost all the analysts in counties have opposed it. Therefore we have struck it out. The opinions received were as follow:—Mr. Horsley considered that it would not do for counties. It would occasion expense and loss of time. And Mr. A. J. M. Edger, Dr. Hassall, Mr. Young, Mr. Scott, Mr. Davies, Mr. Campbell Browne, Mr. Lecbody, and Mr. E. H. Jones, express substantially the same views as Mr. Horsley.

The next proposition is—

"That we maintain that, as public analysts, we occupy a perfectly independent position between the trader and consumer; that we have no interest whatever in instituting prosecutions or securing convictions, these proceedings being taken by the local authorities at their own expense; and that our duty is simply to act as analysts, and carry out the duties of the post assigned to us by the Act."

I have only one remark made by the 57 who have returned answers, and that is by Mr. Collins, who says, "Hardly true. The rejoinder might be, the more convictions, the more public alarm, and therefore more work for analysts."

Dr. CORFIELD: I have very great pleasure in proposing this, and I will say only one or two words, as the time is running short. We have, I think, quite enough to do without trying to do either the work of solicitors or the work of inspectors. I have seen once or twice on record that analysts have tried to do the work of solicitors. At any rate one or two have even done the work of inspectors. I consider that several, or I may say the majority of the mistakes into which some of us have fallen, have occurred from our trying to do the work of solicitors or inspectors. I am very glad I was asked to propose this, as only a few days ago I was the unfortunate recipient, from a person of whom I had never heard in my life, of a more or less insulting letter, in which he assumed that I had originated the proceedings—in fact that I was acting in a spiteful manner towards the tradesmen in my district.

Mr. RIMMINGTON: I have very great pleasure in seconding the motion. I cannot believe that any gentleman in the capacity of analyst can have any other interest than that of serving the intentions of the Act in protecting the public and doing justice to all parties concerned. He ought to know nothing at all about the samples or where they came from. He could not, therefore, entertain any feeling of vindictiveness or any notion whatever of doing anything that is not strictly right.

The motion was carried unanimously.

The SECRETARY: The next proposition has been slightly altered from the form in which it stood on the printed paper—an addition having been made. It now reads—

"That an Association of Public Analysts be formed for the purpose of mutual assistance and co-operation, and that the original members of the Association be the duly appointed public analysts who shall enrol their names at this meeting, or before the end of the current month in reply to a circular notifying the decisions of this meeting."

Mr. WENTWORTH SCOTT: Which would include other analysts besides public analysts.

Mr. WANKLYN: I beg to propose this resolution, and it is hardly requisite that I should make any remarks in proposing it. What I have already said bears upon the subject.

Mr. BLYTH: I beg to second it; I think no remarks are required.

It was carried unanimously.

The SECRETARY: The next resolution is:—

"That after the 1st September all analyists in actual practice shall be eligible for election as members of Association. Each candidate for election shall be proposed by four members of the Association, two at least of whom should testify to his fitness from personal knowledge. The election to be by ballot.

Mr. E. W. T. JONES: I have great pleasure in proposing this resolution. I do not think there are many remarks required upon it, but perhaps I may just say one or two words. I do not think we should be at all selfish just because we have been appointed public analysts, and exclude many equally scientific men who have been practising as analysts, but have not hitherto thought it desirable to take posts as public analysts. They may be thoroughly capable of doing so, and would probably like to be included in the Association.

Dr. TRIPE: I shall be very happy to second that. I think they should be eligible, but at the same time, except they choose to avail themselves of the month of grace during which it says they shall be eligible, then they must come under this resolution, that they shall be proposed by four members of the Association, two of whom must testify to their fitness from personal knowledge of the candidate. I think it is absolutely necessary that those who do not accept of the month of grace offered them to become members *de facto* from their appointments, should produce some testimony as to their fitness to make analyses.

Mr. WENTWORTH SCOTT: I have very great pleasure in supporting the general sense of this, the more so as I have been engaged in somewhat similar work myself quietly for some months past, upon a scheme not only involving public analysts, but private ones; and I think it would be rather objectionable, upon the ground that I will mention by-and-by, to entirely shut out those gentlemen who are not at present public analysts, but who may become so, for anything we know to the contrary, next week or next month, and who in many respects may be of equal or superior knowledge upon food analyses to some of our own body. But I think that anything like an institution which attracts an association of public analysts on one side as a kind of scientific Ishmaelite, who shall be against the public on one side and against the vendors on another, and against all the rest of their profession too, would be rather unadvisable. And, therefore, I think that some means should be found of letting in the outer world in the shape of those scientific gentlemen who are not at present public analysts.

The CHAIRMAN: They may be by-and-by.

Mr. WANKLYN: I think we should pause before we admit people who are not public analysts.

The CHAIRMAN: At the present time.

Mr. WANKLYN: I think we should pause before we admit those who are not public analysts. By making the Society very select, and restricting it to public analysts, we shall derive a certain element of strength. Afterwards it may be matter of consideration whether or not we should not admit others as honorary members. But I think we should not admit any persons as ordinary members of the Association unless they are in actual practice as public analysts. At any rate I think we should be wise to postpone arriving at a conclusion on the subject.

The motion was then put to the meeting, and carried unanimously.

The SECRETARY: The next proposition is, "That the name of the Association be, 'The Society of Practical Analysts.'"

Mr. ALLEN: I have had the resolution put into my hands to propose. Of course if we call it "The Society of Practical Analysts," or "The Association of Practical Analysts," that enables us to extend it, if we should desire to do so afterwards, to include other analysts in practice. At the same time it rather expresses that we ourselves are practical analysts, and I hope all the food analysts who are or will be appointed are literally so; and as far as the name goes, therefore, it is expansive. If we call ourselves "The Society of Public Analysts," it would define it perhaps too closely and restrict it too much; therefore it has been proposed to adopt the title of "The Society of Practical Analysts."

Mr. Heisch: I do not think there is much to remark upon it, and I simply second the motion.

Mr. Wanklyn: I should much prefer that it should be called by the name as it originally stood in a former resolution, "The Association of Public Analysts." There are a very great many reasons why we should make it very special.

Mr. Wentworth Scott: For my own part, Sir, I think that while the term "public" analyst is too restrictive in one direction, that of "practical" hardly conveys a sufficient idea of what we mean, and you would necessarily exclude from our midst some of the first scientific heads of this country by that very term. There are a great many people whom we should be proud to welcome amongst us, hereafter to whom that title would, to my knowledge, be objectionable. I beg to propose that it be, "The Society of British Analysts," which will not be so exclusive.

Mr. E. W. T. Jones: I beg to second it. I think that term will be better than the other.

Mr. Burge: I beg to move that the term "analysts" alone be used without any adjective before it.

Mr. Wanklyn: I beg to propose that it be "The Association of Public Analysts."

Mr. Piesse: I propose that it be called "The Association of Food Analysts."

The Chairman: I think that would not do, because the Act takes in medicine as well.

Mr. Rimmington: The term used in the former resolution is that which is used in the Act of Parliament. It has the authority of Parliament, and I think it would be better to use it. I do not think we can mend it.

The Chairman: Public analysts?

Mr. Rimmington: Yes.

Mr. Heisch: The proposer of the motion is quite willing, and I am also as the seconder, to accept Mr. Wanklyn's amendment proposing the term "public analysts."

The Chairman: It has been proposed as an amendment to the original proposition that the name of the Association be "The Society of Public Analysts."

The proposition was then put to the meeting, and carried with two dissentients.

Mr. Rimmington moved, Mr. Heisch seconded, and it was resolved unanimously, "That the members subscribe 10*s.* 6*d.* each to defray preliminary expenses."

Dr. Tripe observed that it did not define the subscription.

The Chairman replied that that could not be fixed just at present.

The Secretary: The next resolution is:—

"That the following gentlemen be appointed a committee (with power to add to their number), Messrs. Allen, Bernays, Dupré, Estcourt, Hassall, Heisch, Redwood (Chairman), Stevenson, Wanklyn, and Wigner."

Mr. Rogers: I beg to propose this motion:—

"The names are too well known to all here, and to the general public, to require any remark from me."

Mr. E. W. T. Jones: I beg to second it.

Carried unanimously.

Mr. Bell moved, Mr. Burge seconded, and it was carried unanimously:—

"That the committee be requested to draw up a code of rules as the basis for the Society, to be submitted for the approval of the next general meeting.

The Secretary: The next proposition is:—

"That Messrs. Heisch and Wigner be appointed Honorary Secretaries."

Mr. Scott would leave this open.

The Chairman: I am sure, gentlemen, that I can speak personally to the fact that we are greatly indebted to those two gentlemen for having so admirably, up to the present time, conducted all the business relating to the meeting on the present occasion and on previous occasions.

Mr. Burge: I have great pleasure in moving this. It is only necessary to look at the names in order to approve of them.

Mr. Allen: I have great pleasure in seconding the motion, for, having been connected with Messrs. Heisch and Wigner from the commencement, I happen to know what an enormous amount of work has devolved upon them in the organisation of the Society. We ought to thank them for what they have done already, as well as appoint them to act in future.

Mr. Wentworth Scott: I will make a few remarks. My hastily interpolated comment was not in any sense intended as antagonistic to the motion, but simply rather that we might add dignity to it, by its coming really before the public, to my thinking, better as the spontaneous result of this meeting rather than its being "cut and dried" in some chamber beforehand. I have very great pleasure in supporting it as coming with the approval of this meeting, and not as coming from some other place.

Carried unanimously.

The Secretary: The next proposition is:—

"That it be an instruction to the committee to carefully consider the various replies to questions 1 and 2, to revise the resolutions in reference to mixtures and milk; to draw up a definition of adulteration; and, if they consider it necessary, a schedule of exceptions, to be submitted to the next general meeting."

Dr. Tripe: I have great pleasure in moving this resolution. I do not think we need go into this question at all. You have decided that these questions shall be considered, and if you do not refer it to the committee your previous resolution can simply have no effect.

Mr. Piesse seconded the motion, and it was carried unanimously.

Mr. Wanklyn: I wish to move a vote of thanks to the press for the way in which it has taken up our interest, especially the *Chemical News* and the *Lancet*, which has had a well-written series of articles on the subject, and it would be graceful if we were to pass a vote of thanks to the editors of those papers.

Mr. E. W. T. Jones: I have very great pleasure in seconding the excellent resolution of Mr. Wanklyn.

Carried unanimously.

Mr. Piesse: I beg to move a vote of thanks to Dr. Redwood for the excellent manner in which he has presided on this occasion.

Mr. Rimmington seconded the motion, and it was carried unanimously.

Mr. Blyth: I beg to move a vote of thanks from the public analysts, as a body, to the committee who have called this meeting, and who have laboured so much for us. They have no benefit from their labour with the exception of our thanks, which I think we must give them most heartily.

Dr. Tripe seconded the motion, and it was carried unanimously.

The Chairman: Gentlemen, perhaps I may be allowed to speak on behalf of myself and the committee, and to thank you for your thanks, and to state that it has been really a labour of love to us. It has afforded all of us, I am sure, much pleasure in being able to carry out the several views which you have ratified on the present occasion. I must state, however, that it is to three or four gentlemen around me, more than to myself, that you are indebted for what has been done previous to this meeting. This, however, you may depend upon, that the committee will continue to devote their best attention to your interests.

The Pharmaceutical Journal.

SATURDAY, AUGUST 15, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE EXCURSION.

A BRIGHT sun and refreshing breeze, a lovely country and the pleasantest of company, together with excellent arrangements carried out without a single hitch, formed a "fortuitous concourse of atoms" which rendered the excursion of the members of the Conference on Saturday last a decided success. Just before eleven in the morning of that day a company numbering about one hundred and thirty pharmacists and philopharmacists, including a goodly sprinkling of ladies, left Paddington for Great Marlow, where they arrived, not quite so soon as was expected, but as early as the exigencies of a single line of rails beyond Taplow would allow. At Marlow, "light refreshments" having been partaken of, the re-invigorated travellers went on board the barges which were to convey them down the stream.

It were vain to attempt here to describe the charming scenes that presented themselves one after another as the barges glided past Cookham Dean and Cookham to Cliefden; the wooded hills on the southern banks, the verdant islets in the river, and the more extensive range of country visible beyond the less bold northern banks. Nor is it possible to tell the added beauties which were seen when, abandoning the smooth vibrationless travelling of the barges, the company climbed, under the guidance of the head gardener, to the height where once stood "Cliefden's proud alcove," erected by the witty and profligate GEORGE VILLIERS, Duke of Buckingham, afterwards used as the residence of FREDERICK, Prince of Wales, and destroyed by fire at the close of the last century. Whatever may have been the attractions of the Cliefden of POPE'S song, there was a general agreement of opinion among the visitors, whilst strolling through the present conservatory, where beautiful leaves vie with lovely flowers, or wandering through the grounds where the *ars celare artem* has been so successfully exercised, that the kind courtesy of the Duke of WESTMINSTER had contributed materially to the enjoyment of the day.

Once more on board the barges, the party was towed past fresh umbrageous hilly wonders—which now lined the northern bank of the river—until Maidenhead was reached. There the *déjeûner* was ready, as were also those who were to partake of it, and the next hour was spent in discussing the incidents of the trip and the merits of the viands, and in paying a well-merited compliment to the Local Secretary, Mr. MICHAEL CARTEIGHE. The company then broke up into groups, which, after paying their devotions at the shrine of FLORA, TERPSICHORE, OLD FATHER THAMES, or perhaps some better-loved deity, reunited at the Taplow Station. A quick run to town, followed by a general hand-shaking, and this most successful effort for the welfare of pharmacy was at an end. *Au revoir!*

ADULTERATION DEFINITIONS.

WHAT is an adulteration? What is food and drink? What is a drug? These are all questions that have arisen during the administration of the Adulteration Act, but which that Act has not always satisfactorily answered. Mr. ARNOLD'S opinion, for instance, that sweet spirit of nitre could not be considered a drug in the proper sense of the word, was not accepted without question, although it had some foundation in the origin of the word and trade practices, and it is possible that, had his decision in the Westminster case been based on that opinion, it would have increased the already abundant litigation to which absence of definitions from the Adulteration Act has given rise. In Canada, however, the Dominion Legislature has sought to facilitate the operation of an Adulteration Act which it has recently passed by defining the terms, "food," "drink," and "drug," as follows:—*Food* is to mean and include every article used as food in the state in which it is offered for sale, or that is used in the preparation of food by admixture therewith, either before, during, or after cooking. *Drink* is to mean and include any liquid used as a beverage and any article used in or for the preparation or part preparation of any beverage. *Drug* is to mean and include all articles used for curative or medicinal purposes.

With respect to the term "adulteration," concerning which there exists in this country such diversity of opinions, it is provided that it shall mean the admixture of any deleterious ingredient, or any material or ingredient of less value than is understood or implied by the name under which the article is offered for sale. In a schedule of articles which are to be deemed deleterious to "drink," are included cocculus indicus, common salt, copperas, opium, Indian hemp, strychnine, darnel, sud, extract of logwood, salts of zinc or lead, and alum, or compounds of them. The admixture or offering for sale articles of drink mixed with any of these substances is to be punished on the first offence by a fine of one hundred dollars. One point of novelty in the Canadian Act is that it allows the dealer the privilege of retaining under seal a portion of the samples sold. Perhaps by the time the Government is ready to introduce a Bill for the amendment of the English Act, some experience of the value of the above definitions may be available.

Our readers will be glad to see from the report printed in the preceding pages that a vigorous effort is now being made to place the whole subject upon a more satisfactory footing, and we hope that the new Association which has been formed will soon take an authoritative position in the guidance of public opinion in matters relating to adulteration.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

July 28*th*, 29*th*, 30*th*, *and* 31*st*, 1874.

Present—Messrs. Ainslie, Buchanan, Gilmour, Kinninmont, Tait, and Young.

Dr. Greenhow was present on the 28th and 29th of July, and Professor Maclagan was present on the 28th, 29th, and 30th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Two candidates were examined. *One* failed. The following passed, and was declared qualified to be registered as a Pharmaceutical Chemist :—

Selkirk, James ....Edinburgh.

MINOR EXAMINATION.

Forty candidates were examined. *Twenty-one* failed. The following *nineteen* passed, and were declared qualified to be registered as Chemists and Druggists :—

*Currie, Robert Kirkwood ......Glasgow.
*Cumine, Rupert Henry ....Kingston-on-Thames.
Frazer, Samuel McCall ....Glasgow.
Arthur, Charles.......................Edinburgh.
Baildon, Henry Bellyse ....Edinburgh.
Oakes, Henry ....Pickering.
Equal. { Bell, John Armour ....Glasgow.
Equal. { Robbie, William ....Aberdeen.
Wright, Robert.......................South Shields.
Murray, Matthew David.........Annan.
Equal. { Amery, John..........................Taunton.
Equal. { Anderson, George A. Coulson...Bournemouth.
Bullock, John Alfred ....South Shields.
Nockolds, Stephen William ...Horsham.
Equal. { Midgley, James Herbert.........Edinburgh.
Equal. { Thompson, James Hood ....Berwick-on-Tweed.
Alexander, Alexander ....Aberdeen.
Francis, James ....Liverpool.
Broadbent, Sidney ....Greenfield-in-Saddleworth.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Six candidates were examined. *Two* failed. The following *four* passed, and were declared qualified to be registered as Chemists and Druggists :—

Bingham, Robert ....Hull.
McDonald, Angus....................Glasgow.
Saunders, Frederick.............Manchester.
Young, John Matthew ....Glasgow.

PRELIMINARY EXAMINATION.

The certificate of the University of Cambridge was received in lieu of the examination of the undermentioned :—

Baildon, Henry Bellyse ....Edinburgh.

* Passed with Honours.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 119.)

After the President's Address the reading of papers was proceeded with. The first paper was on—

Pharmaceutical Tests for Cinchona Bark.

BY DR. J. E. DE VRIJ.

Notwithstanding the voluminous literature about cinchona barks, there are still many links wanting in our knowledge of this valuable medicine.

Thus for instance, although we are tolerably well acquainted with the chief therapeutical agents contained in good barks, viz. :—

1. Cinchona Alkaloids,
2. Cinchotannic Acid,
3. Kinovic Acid,

we know very little about the state in which they exist in the bark, and hence the little therapeutical value of many of the pharmaceutical preparations of bark.

Besides the powder which naturally contains the three mentioned therapeutical agents, I am only acquainted by my own experience with one pharmaceutical preparation which equally contains them, but without the vegetable fibre, viz., the alcoholic extract of bark. Water is, however, frequently the solvent used in the pharmaceutical preparations of bark, and, therefore, as I have found by experience that the quantity of the therapeutically active substances extracted by cold water from bark is very different in using different kind of barks, I consider that it will be beneficial for the pharmacist, if he is able, to test the bark which he wishes to use in his pharmacy.

The tests prescribed by some Pharmacopœias, besides that they require too much time to be generally applied in all pharmacies, are too one-sided, as they only determine the quantity of the total alkaloids, or of the quinine contained in the bark. This determination alone, although sufficient for the quinine manufacturer, is not so for the pharmacist.

If the physician in prescribing bark, or any of its pharmaceutical preparations, had only in view to prescribe the alkaloids contained in them, he would do much better to prescribe the alkaloids themselves, and I suppose, therefore, that he intends to apply also the other active substances of which the astringent matter, called cinchotannic acid, is preponderant. During my numerous investigations of Indian barks, I have found, by a pure accident, that the relative quantity of this substance in different barks may equally be ascertained, together with that of the alkaloids, in the following manner :—

One part of powdered bark is mixed with about four parts of distilled water to form a thin semi-fluid paste, which, after some hours' maceration, is packed in a percolator. When the liquid has percolated, more water is poured into the percolator till four parts of clear liquid are obtained.

To apply the test this liquid is divided into four equal parts.

One part is tested by strong hydrochloric acid.

One hundred grains require about fifty minims of acid.

Another part is tested by clear lime water, which is added till the liquid has a decidedly alkaline reaction.

These reactions, in applying them to different barks, will, after some experience, enable the operator to judge the pharmaceutical value of the barks, and convince him, for instance, that the Indian barks are in general better adapted for purely pharmaceutical purposes than the American barks.

This is illustrated by examples of the following Indian barks :—

1. Calisaya, from Java.
2. Hasskarliana seu Calisaya hybrida.
3. Officinalis (Ootacamund).
4. Pahudiana (Java).
5. Succirubra (Jamaica).
6. Ditto (Ceylon).
7. Bark from Apothecaries Hall, alk. 8 per cent., $[\alpha]j = 38{\cdot}3$ ↰ ; Indian succirubra.

If the operator wishes also to estimate the relative quantity of the total alkaloids, he may easily do so by testing a measured quantity of the percolated liquids by a standard solution of tannic acid, by which he can compare the amount of alkaloids fit for pharmaceutical use contained in the different barks subjected to his investigation.

The President : I am sure you will feel with me that we are highly favoured by the presence of Dr. De Vrij. I agree with him that we have yet a great deal to learn respecting these barks, probably, as I have already said, for their proper study, the labour of a life would be required. I am quite incompetent to criticise in any way Dr. De Vrij's statements, and probably after we have seen them in print we shall be able to make more of them. I am happy to say, however, that Mr. Broughton is present, who is also an authority on Indian barks, he being chemist to the Government on the cinchona plantations in India. We shall be happy to hear any remarks from him.

Mr. Broughton: I have listened with very great interest to the able paper we have just heard. The subject of the cinchona barks of India is rather a large one, and I shall not be able in the short time at your disposal to give any very general information on the subject; but I may mention that in the course of my work, I have determined with some precision the state of the alkaloids as they exist in the green bark. I find they exist nearly in the proportion of one-fifth of their total quantity as quinate, and the remainder as cinchotannate. The method by which I determined this point was as follows:—I obtained a quantity of fresh green bark of the *Cinchona succirubra*, and had it squeezed in a powerful press until it became nearly dry; but in order to be quite accurate the amount of water remaining was also determined. I found on analysis of the liquid which came from the bark, that one-fifth of the total alkaloids in the bark, which was also determined by analysis, was to be found in the liquid squeezed from it. I also determined the amount of alkaloids left in the bark after squeezing, and found that four-fifths of the alkaloids in the bark existed, after the soluble portion had been expressed, as tannates. Tannates of the alkaloids are but very slightly soluble in water, and it is for this reason that there is such a difference in barks on testing. If a bark contains a large amount of tannates, and has been kept for a year or a year and a-half, the tannate is oxidized, and forms an insoluble compound, with very little taste; but if, on the other hand, the alkaloids in the bark exist as quinates, the bitter taste is very perceptible, even after long preservation. I quite agree with Dr. De Vrij as to the very variable character of barks. For instance, the bark of the *Cinchona officinalis* has totally different characters, on analysis, in taste, in quinine, and in tannic acid, to that of the *C. succirubra* or the red barks. The quinovin in the bark, which is a very general constituent of all the cinchona barks I have met with, exists, not in combination with the alkaloids, but in an insoluble state, and only becomes apparent when the bark is exposed to the action of an alkaline solvent. I do not know that I can add anything more of special interest, and, as I have already said, the whole subject of Indian barks is too large to enter upon now.

The President: Are the barks ever treated in India in the green state for the production of quinine on a commercial scale?

Mr. Broughton: All the barks used in India are employed in the green state; but we do not make sulphate of quinine. The whole of the alkaloids are precipitated together, and so employed in medicine. The reason of that is that the succirubra, which is the most common of all the Indian barks, contains a very small proportion of quinine, but a large amount of cinchonidine. And it has been found, by very careful medical experiments, numbering, I believe, some 4,000, that cinchonidine is almost, if not quite, equal as a febrifuge to quinine. There has been no advantage found, therefore, in separating the alkaloids, as has been the custom for pharmaceutical purposes in this country.

Mr. Umney: I regret that I was not present at the beginning of Dr. De Vrij's paper, but I should wish to add that I have been working for some time at the fluid extract of cinchona, and have in my hand an incomplete paper on the subject. I have been more especially working at processes for the production of a fluid extract, because, as we all know, the process of the British Pharmacopœia is a most wasteful one, the amount of alkaloid left behind being almost as great as that dissolved by the water; perhaps about 60 per cent. is taken out, and about 40 per cent. left in. I certainly look upon the fluid extract of the British Pharmacopœia as an unnecessary concentration. It by no means follows, if you have fine Calisaya bark, that you will get a good fluid extract; on the contrary, sometimes the finest barks will not yield more than 18 or 20 per cent. of completed fluid extract, and this unsatisfactory. If you search the Pharmacopœias of Germany, America, and I doubt not others also, you will find no fluid extract carried to such a degree of concentration as we have in this country. The fact is we still follow the process given some forty years ago before the College of Physicians, when very little was known about cinchona bark. But I think we might well take as a standard the other fluid extracts of the Pharmacopœia, and make this extract of the strength of one drachm to the fluid drachm, and I believe that percolation with proof spirit for Fluid Extract of Bark would answer very well. I may also say that I have recently examined the fluid extracts of cinchona of trade, and in the majority of cases I am confident they are being made from Indian barks which do not contain quinia. After what Mr. Broughton has said, I am sure we shall not dispute that these barks are equal, if not superior, to those of South America in many respects; but as the matter stands at the present time, we have no right, according to our Pharmacopœia, to substitute these Indian barks, containing no quinia, for the Calisaya bark there prescribed. I say this because I find, on examination, that not more than one-fifth of the trade specimens yield a trace of quinia—almost the whole of the alkaloids in the fluid extracts being cinchonine and cinchonidine. I have made a fluid extract from some of the barks grown in India, containing 4 to 4½ per cent. of crystallizable sulphate of quinia, and these barks yield a beautiful fluid extract, and to such substitution I do not object. I hope shortly to publish many of the experiments I have made in this direction.

Mr. D. Hanbury: Is not Calisaya bark grown in Ceylon as well as in Bolivia?

Mr. Umney: Undoubtedly; but I referred to the flat Calisaya bark of the Pharmacopœia, such as we are accustomed to see from South America.

Mr. Giles: Unfortunately, every pharmacist who has anything to do with the manipulation of barks, must feel that this subject is one which requires the study of a life, and that it cannot be sufficiently exhausted, even by those who only are qualified to lead us in such matters—the chemists. In pharmacy we are all floundering about, and coming to the conclusion that such a thing as an efficient formula to represent the cinchona barks does not exist, though it is a great desideratum. I entirely concur in the observations which have been made by Mr. Umney as to the mistake in the preparation of the liquid extract; I think the process is carried too far, that it is wasteful, and totally unsatisfactory in its results. Frequently the extract, when it comes to be diluted to an extent which ought to bring it back to something like the pristine condition as obtained from the bark, is a horrible combination like mud and slime, offensive to the taste, and likely to disturb an unsettled stomach instead of being advantageous to it. When I examine barks for the purpose of obtaining one suitable for a liquid extract, it generally happens that I have to try half-a-dozen samples, which is a very tedious process, and I am sure we shall all welcome any suggestions from Dr. De Vrij, which will enable us to arrive more quickly at a conclusion. I have not found any experiments of any value except actual manipulation, and I generally take about seven pounds of bark, make an extract from it, and if it answers well, buy it. Of late years, however, it has been very difficult to get a bark at all satisfactory; sometimes you get one yielding a good product, but it is difficult to get a fair return for the original cost of the bark; and it is much more common to get a copious result, which is altogether distasteful—harsh, acrid, disagreeable, not bitter, and not fit to be sent out. This whole subject is in a most unhappy state, and we are all deeply indebted to Dr. De Vrij for bringing his scientific knowledge and practical experience to bear on the pharmaceutical aspect of this question. I believe cinchona bark is not only valuable in itself, but infinitely more valuable than quinine, and that no greater mistake has been made than in confining our attention to quinine, and rejecting all the other alkaloids. What we really want is to produce something which shall be cinchona bark *minus* the woody fibre. That is the great problem; it has occupied a great deal of my attention, because it presents more difficulties than almost any other, and it is utterly beyond my power to resolve. I hope Dr. De Vrij will kindly devote still further attention to the pharmaceutical aspect of this subject.

Dr. De Vrij begged to thank those gentlemen who had spoken so kindly of his efforts as to encourage him to continue his researches. He had heard with great satisfaction the remarks of Mr. Giles, which reminded him that some weeks ago he had been asked to deliver a lecture before the Society of Physicians of Holland on cinchona and its alkaloids from a medical point of view. He then gave a sketch of what was known of cinchona from its first introduction into medicine, and the unhappy fact that, by an entire accident, quinine only had received attention, the other alkaloids being almost neglected. He then went on to give it as his opinion that the only form in which cinchona ought to be prescribed was that of alcoholic extract, and that in order to make such an extract they should not use the Calisaya bark (which was much superior to all other kinds for making quinine), but the red barks, particularly those of India, they being much richer in the alkaloids in general, though not in quinine, and also in cinchotannic acid. He had lately had a proof of the efficacy of such an extract in his own family; the physician who had been attending his sister, after giving her sulphate of quinine, saying this must be followed by bark, but that as he (Dr. De Vrij) was better acquainted with the best forms, he would leave it to him to select it. On talking with the physician, he said he would make an extract, and tell him how much he got from a certain amount of powder, and he could then prescribe the dose. The physician ordered three grains to be taken four times a day, and it proved perfectly successful. Since then this physician had prescribed no other preparation of bark, and many others had also adopted it. Looking to the therapeutics of the future, he did not think quinine would be superseded, because it was a most valuable medicine, but he hoped to see introduced the mixed alkaloids from *Indian* red bark, which would in many cases be more useful. It would be desirable that the manufacture should be undertaken by some firm of established repute, possessing public confidence, because it would be very difficult for pharmacists in general to test it. He found no difficulty himself, because he was accustomed to use the polariscope, by the aid of which he could easily detect the red barks of India, as they possessed, on an average, a molecular rotation of 38° to the left.

Mr. Brady: I should like to ask what is the proper strength of alcohol requisite to form a preparation of the bark.

Dr. De Vrij: The alcohol should be of a strength of about 80 or 85 per cent. There is one observation I ought to have made, viz., that the Dutch and English are in many respects very much alike. One gentleman asked if it was allowable to use Indian barks for the preparation of the extract, and I am sorry that such a question should have to be put. But unfortunately both nations have done the same thing: they have both introduced the cultivation of bark in their Indian possessions, but neither allowed its pharmacists to use them; and not only so, but they have both lately had an appendix to the Pharmacopœia issued, and in neither is there any mention of the Indian barks.

Mr. D. Hanbury read the following paper by Professor Flückiger on "The Stearoptene of Oil of Nutmeg:"—

On a Substance called Myristicin.

BY PROFESSOR FLÜCKIGER, OF STRASSBURG.

From the statements recorded in Gmelin's *Handbook of Chemistry*, vol. xiv., p. 389, it would appear that the essential oil of nutmegs sometimes deposits a kind of camphor. The earliest notice of such a body is due to Johann Friedrich John, professor of chemistry, at Berlin, who, in the year 1821, made very extraordinary observations regarding nutmeg-camphor. Thus, according to that chemist, the substance under notice, which he termed *Myristicin*, is soluble in water, and even requires not more than 19 parts of boiling water for solution. We know of no other substance of the class of natural stearoptenes or camphors being to any considerable extent soluble in water. But still more astonishing is the assertion quoted by Gmelin, that the aqueous solution of myristicin is "*sometimes acid, sometimes alkaline!*" John even states that myristicin yields crystallized compounds with hydrochloric or tartaric acids! He, in fact, thought the substance to be a kind of alkaloid, a suggestion which may be excused when we remember the brilliant discovery of cinchonine and quinine which had been made shortly before by Pelletier and Caventou.

I am sorry to have been unable to see John's original paper in order to ascertain how he obtained this curious camphor.* Nor have I perused that of Bley, whose few observations, however, as found in Gmelin appear, to refer to an impure substance, inasmuch as he says his stearoptene melted above 100° C., leaving carbon when evaporated.†

Again, in 1839, Mulder examined a crystallized stearoptene, which is also noticed by Gmelin. This substance is likewise said to be soluble in boiling water as well as in *caustic lye;* Mulder assigned to it the formula, $C_{16} H_{32} O_5$, and represented it as melting at 112°C. From his paper it appears that he obtained it not, as supposed by Gmelin, from nutmegs, but from the essential oil of mace. As to the latter, there is found in Gmelin an observation of Bley's, according to whom this oil yielded an *emulsion with ammonia*, and a kind of *soap* with caustic lye.

Oil of nutmegs was again examined by Cloez in 1864; and oil of mace in 1862 by Dr. Schacht, of Berlin, and in 1865 by Koller; no one of these observers mentions any stearoptene.

The foregoing statements concerning the so-called *Myristicin* induced me to endeavour to procure this remarkable substance; and in this object I was aided by the kind liberality of Messrs. Herrings and Co., of London, In the laboratory of these gentlemen, there was submitted to distillation a large quantity of nutmegs, some of them being of the ordinary kind (*Myristica fragrans*), while others were the *long nutmegs* derived from *M. fatua.* On the third day of the distillation, a crystalline matter was noticed to collect with the oil on the surface of the water.

This was the substance which I received of Messrs. Herrings and Co. It was a greyish semi-solid mass, smelling strongly of nutmegs. By mixing it gradually with cold spirit of wine, sp. gr. 0·830, I found that the crystalline part of the magma might be separated and partially purified by washing with small quantities of spirit of wine. The crystals thus obtained have to be further purified by repeated crystallization from boiling spirit of wine. At length large, brilliant, colourless scales were obtained, the crystalline form of which, however, could not be ascertained, the scales being never fully developed; in polarized light they prove to be doubly refractive. The re-crystallization was repeated ten or twelve times, yet was ineffectual in removing from the substance the smell

* In the abstract of John's paper as contained in the *Journal für Chemie und Physik* of Schweigger und Meinecke, xxxiii. (1821) 250, myristicin is simply said to be deposited in the essential oil of nutmegs.

† Such is the statement in the English translation of Gmelin.

of nutmeg. It is, in fact, not possible to deprive it in this way of the odour; yet the odour is gradually lost when the crystals have been kept for some months, although even in a stoppered bottle. They are readily soluble in warm alcohol, crystallizing therefrom when sufficiently pure, even in summer, but separating more readily in cold weather.

The alcoholic solution is devoid of rotatory power; it reddens litmus slowly, but very decidedly and permanently. In water the crystals are insoluble. They melt at 54·5° C., and evolve offensive vapours, like a fatty substance; if they are heated in a glass tube, no crystallized particles are sublimed. On platinum foil they burn, leaving no residue, giving off at first the same vapours as when heated in a glass tube.

No difference whatever could be observed between the myristicin of *Myristica fatua* and that of the common nutmeg; the ultimate analysis of purified crystals from both sources likewise corroborates their identity. Crystals from *M. fragrans* afforded—

Carbon	75·77
Hydrogen	12·19
Oxygen	12·04
	100·00

while those from the oil of the long nutmeg, *M. fatua*, yielded:—

	I.	II.	III.
Carbon	75·23	75·66	75·02
Hydrogen	12·30	12·36	12·35
Oxygen	12·47	11·98	12·63
	100·00	100·00	100·00

In caustic alkalies the crystals of "*Myristicin*" dissolve readily; if a somewhat considerable quantity is dissolved in warm caustic lye, it will form, on cooling, a consistent jelly, which, in fact, is nothing else than a *soap*. Myristicin warmed for a day or two with absolute alcohol and an excess of anhydrous carbonate of sodium, yields, on cooling, a gelatinizing *neutral* solution. If this solution is liquified, filtered, and mixed with an acid, a crystalline layer will, on cooling, make its appearance on the surface of the liquid. This layer may be collected, washed with water, until the latter no longer reddens litmus, and then re-crystallized from hot alcohol, when crystals are obtained which prove to agree in every way with the original "*Myristicin.*" If this process of purification is repeatedly carried on with the same quantity of the substance, the odour of the latter diminishes, and at last disappears.

The crystals thus purified proved, upon analysis, to be composed of—

	I.	II.
Carbon	73·27	73·41
Hydrogen	12·25	12·25
Oxygen	14·48	14·34
	100·00	100·00

It became now evident that I had before me *Myristic Acid*, which, in form of *Trimyristicate of Glycerin*, is the chief constituent of the fatty part of nutmegs. The formula of the acid, $C_{14}H_{28}O_2$, requires:—

14 C	168	73·68
28 H	28	12·28
2 O	32	14·04
	228	100·00

The melting point of myristic acid is stated by Heintz to be 53·°8; my crystals melted not before 54° or 54·5°. Whether this difference is due to the perfect, I may say unrivalled, purity of my acid, or to a different way of observation, may remain undecided.

The "*Myristicin*" under notice is consequently nothing else than Myristic Acid, accompanied at the outset by essential oil. Whether the same mixture had been examined by John, by Bley, or by Mulder cannot be ascertained. It is obvious that some of their observations would agree with myristic acid, whereas others rather apply to a camphor, the existence of which has not been corroborated.

It is not astonishing to meet with myristic acid in the product of a prolonged distillation of nutmegs, for fatty acids generally are capable of being volatilized, especially by means of superheated steam, when the vegetable fats are resolved into glycerin and fatty acids. I am not aware, however, that special observations had ever been made as regards myristic acid. It is possible that free myristic acid is present in the nutmeg itself, and this would still more easily be carried over by the watery vapour. I have warmed a little powdered nutmegs with alcohol and anhydrous carbonate of sodium, and thus got a small amount of indubitable soap, from which I isolated myristic acid. This experiment shows that nutmegs contain a little myristic acid in addition to that combined with glycerin. As to the volatility of myristic acid, I may lastly remark that *Lauric Acid*, $C_{12}H_{24}O_2$, which is the next in the same series as myristic acid, has been found by Görgey and by Oudemans to be easily volatilized with steam. Myristic acid may doubtless be a little less volatile.

Myristicate of sodium had not yet been obtained, so far as I know, in distinct crystals; there is, however, no difficulty in preparing it in thin prisms, which are deposited if an alcoholic solution of the salt is allowed to evaporate very slowly. By mixing an alcoholic solution of this salt with an alcoholic solution of acetate of barium, I obtained an amorphous precipitate of *myristicate of barium*, 0·419 gramme of which yielded by incineration 0·142 gramme carbonate of barium, representing 0·0988 of barium, that is, 23·55 per cent. of that metal. The formula 2 $(C_{14}H_{27}O_2)$ Ba would require 23·15 per cent. The liquid, which I separated from this myristicate of barium yielded, after a short time, crystalline scales of another salt, namely, 2 $(C_{14}H_{27}O_2)$ Ba + 2 H_2O, which has not been obtained by other observers. This salt should yield upon incineration 31·39 per cent. of carbonate of barium; 0·2055 gramme of the crystals actually afforded me 0·0645 of carbonate, that is to say, 31·38 per cent.

By mixing an alcoholic solution of nitrate of silver with an alcoholic solution of myristicate of sodium, I obtained amorphous *myristicate of silver*, $C_{14}H_{27}AgO_2$, which, by theory, should give 32·24 per cent. of silver:— 0·7785 gramme of this salt was found to contain 0·2506 of silver, that is to say, 32·19 per cent.; in a second experiment 0·6450 of the same myristicate of silver left 0·2077 = 32·20 per cent. of metal. All these results are in full accordance with my previous statements, namely, that the crystalline matter separated from oil of nutmegs in the laboratory of Messrs. Herrings and Co., is *Myristic Acid.**

The PRESIDENT: Dr. Flückiger has pursued this subject with his usual thoroughness, and we are all indebted to him for so elaborate a paper. It is not a subject of the highest importance, but truth is always valuable. I imagine this crystalline body is often met with by pharmacists in making spirit of nutmeg. I often find a small deposit at the bottom of the bottle, which I have always regarded as stearoptene, but which is probably this myristic acid. I doubt not you will pass a vote of thanks to Professor Flückiger for his paper, which you will please signify in the usual way.

Mr. SIEBOLD: I should like to ask if it be possible to incinerate myristicate of barium without at the same time converting a considerable quantity of the carbonate left into the oxide. Whenever I have incinerated any preparation of barium containing an organic acid, I have always found it impossible to obtain pure carbonate as a residue.

---

* Some of the above analytical results have been ascertained in my laboratory by Dr. Buri.

Mr. Williams: Carbonate of barium stands a high temperature much better than carbonate of calcium, which is apt to become caustic.

Mr. Siebold: Whenever a barium salt containing an organic acid has been heated, I have always found that the residue was not pure carbonate, because the carbon which is present greatly facilitates decomposition.

Professor Tichborne: I would suggest that it is very easy to recarbonate any oxide of barium which is formed, by a little carbonic acid, or water aërated with carbonic acid.

Election of an Honorary Member.

The President: I have a recommendation to make to you with reference to adding to our list of honorary members. We have had the misfortune within two or three years to lose two very important honorary members, Messrs. Procter and Parrish, both Americans. I have now to ask you to elect a Canadian gentleman, Mr. W. Saunders, of London, Ontario. He is well known as a scientific pharmacist, both in America and here, and his communications often appear in our Journal. One was published last week on the insects that attack drugs. I think we may all feel honoured by electing him as an honorary member.

The election was unanimously agreed to.

The Exhibition of Objects of Interest relating to Pharmacy.

The President then proposed that the following gentlemen should be appointed a Committee to report upon the exhibition of pharmaceutical matters—Messrs. Atherton, Barnes, Deane, Gale, Giles, Ince, Martindale, Stanford, and Umney.

The names were unanimously approved of.

The Conference then adjourned for luncheon until two o'clock.

(To be continued.)

EXHIBITION OF OBJECTS OF INTEREST RELATING TO PHARMACY.

(Continued from page 120.)

In room No. 2 were exhibited several beautiful specimens of alkaloids, etc., by Mr. T. Morson. Those of narceia and podophyllin, thymic acid, crystallized hydrochlorate of morphia, and aconitine were particularly fine, while the glacial phosphoric acid had almost the brilliancy of a diamond.

Besides these were a series of all the different kinds of opiums, including English and Australian opiums; a Chinese opium-smoking apparatus, and a picture of a laboratory by Muller.

Messrs. Hopkin and Williams exhibited a number of new medicinal agents, some of the chemicals being splendidly crystallized. Among those more particularly worthy of note were monobromo-camphor, used in neuralgia; double cyanide of potassium and zinc, used to obtain hydrocyanic acid; sulpho-carbolate and permanganate of zinc, used for injections; and redistilled chloral hydrate and croton chloral hydrate, both being perfectly pure, and not showing the least trace of moisture. Among the liquid preparations exhibited by the same firm were nitrite of amyl and nitrate of amyl, the latter of which is so frequently ordered in mistake for the nitrite, from which it differs in physiological effect; trimethylamine, pure aldehyde, and specimens of oleate of mercury, containing 5, 10, and 20 per cent. of oxide of mercury respectively.

Messrs. Schmedes and Co. exhibited samples of chemically pure glycerine, sp. gr. 1·260, and crystallized glycerine, sp. gr. 1·265. Unfortunately, the heat of the weather prevented its assuming during the evening the crystalline form which it presents in the winter months.

Messrs. Corbyn, Stacey, and Co. exhibited a double valve inhaler, which is used in a box lined with baize to prevent loss of heat.

Messrs. Davy, Yates, and Routledge exhibited handsome specimens of biniodide of mercury, valerianate of quinine, benzoate of ammonia, and other chemicals.

An extensive series of chemical apparatus including wine-testing apparatus sets for volumetric analysis, for laboratory students, urinary cabinets, and pure chemicals for analytical purposes, were exhibited by Mr. M. Jackson.

Specimens of eau de Cologne, from most of the makers in Cologne, lent by Mr. F. C. Clayton, attracted a fair share of attention.

The India-rubber and Telegraph Works Company exhibited sections of submarine cables, medical coils and batteries, block-signalling instruments, and many useful articles made of ebonite for medical and pharmaceutical purposes. The patent Léclanché battery, made by this company, is remarkable for quickly arriving at its maximum strength, and its electro-motive force being 75 per cent. greater than Daniell's battery, whilst its resistance is 90 per cent. less. Other articles of interest in this room were improved soda-water bottles by Messrs. Barnett and Foster; electrical apparatus by Messrs. Zimmermann and Co.; improved gazogenes by M. H. Maldine; rotary pill machines, worked by hand or treadle, with improved presses for piping the pill-mass, by which from ten to thirty pounds of pills can be made in an hour, exhibited by Mr. J. M. Pindar. A collection of analysed drugs, pharmaceutical preparations, and a materia medica cabinet were exhibited by Messrs. Southall and Co., of Birmingham, as well as quinovia cocoa and chocolate, in which an extract containing the whole of the active principles of yellow cinchona bark is combined with cocoa, in the proportion of 15 grains of the former, to 4 ounces of the latter. Judging from the rapidity with which the quinovia chocolate lozenges disappeared, they must have been very palatable, and the bitterness of the quinovia completely masked. Messrs. Lynch and Co. exhibited a portable miniature water-bath; improved Higginson's enema, in which the tubes unscrew to admit of cleaning the valves, and the box is so made that the india-rubber tubes are not liable to compression; the best corkscrew mounts to insert in eau de Cologne or other bottles with short corks; and many other improvements in druggists' sundries which were well worthy of examination. Messrs. Roberts and Co., of Paris, exhibited improved enemas, and a goudronière or apparatus for diffusing the odour of tar. This consists of about six metallic perforated plates immersed in a metallic box half full of tar, the plates being attached to the lid of the box; when the lid of the box is raised it is supported by a spring, and the plates then expose the tar on their surface to the action of the air. Wafer envelopes and various dragees were also exhibited by the same firm. On the walls of rooms Nos. 1 and 2 were exhibited some interesting photographs of solar spectra, lent by Mr. J. Norman Lockyer, F.R.S.; a photograph of the house in which Priestley was born, presented by Mr. R. Reynolds, of Leeds, to the Council of the Society; some exquisite paintings lent by Mr. Vokins. In room No. 3, a large and most interesting collection of medicinal and economic plants, from the gardens of the Royal Botanical Society, were exhibited by Professor Bentley, among which we noticed healthy and vigorous young plants of *Eucalyptus globulus*, *Cinnamomum Zeylanicum* and *Cassia*, *Guaiacum officinale*, *Elettaria Cardamomum*, *Picræna excelsa*, *Quassia amara*, *Saccharum officinarum*, etc. Paper made from the bark of various species of Eucalyptus, and other Eucalyptus products, were also exhibited by Professor Bentley. A healthy young plant of the Calabar bean was exhibited by Mr. G. B. Francis. By the same gentleman was exhibited a jar of benzoinated lard, which was shown at the Conference meeting at Nottingham, in 1866. This specimen, after the lapse of eight years, apppeared to be perfectly free from rancidity. In this room were also specimens of labels of every conceivable kind, poison books, &c., by Messrs. Silverlock and Co.; French medicinal preparations, including Eucalyptus products, various dragees and capsules, exhibited by Clin and Co.; and a double-action tincture-press, by Messrs. Lynch and Co.

Messrs. Goosey and Rogers exhibited some very neatly spread adhesive and marginal plasters.

In room No. 4, the microscope room, Messrs. Tisley and Spiller's compound pendulum apparatus, recording the vibration of one or more pendulums in a series of exquisitely curved lines, attracted much attention, and the figures thus made were, through the kindness of that firm, distributed among and eagerly sought after by the visitors.

The recording thermometers of Messrs. Negretti and Zambra were here exhibited. One of these ingenious instruments records the temperature at any depth of the ocean, etc., being so arranged that when let down to the required depth, the first pull upwards causes the thermometer to become reversed, and by this means records the temperature at that depth, on the opposite end of the thermometer tube. Another thermometer records the temperature at any given time of day or night, being connected with a clock which, instead of sounding an alarum, reverses the thermometer at the time for which it is set, and so records the temperature. Among the objects exhibited by Messrs. Steward and Co., may be mentioned a curious and ingenious instrument lately patented, termed a cuiminoscope. It consists of a concave mirror ground to a particular curve, so that when a carte-de-visite is placed in front of the mirror at focal distance, the carte appears of full life-size. Among some beautiful transparent injections of animal tissues, was a full-length section of human kidney, and another very interesting one of the skin of a salamander. Their students' educational microscope is also worthy of note, as being one of the best made at a low price, the object glasses being of English make. Messrs. Baker and Co. exhibited a cabinet containing 144 pharmaceutical slides, comprising sections of roots, barks, seeds, and alkaloids, making altogether a most valuable series, which deserves a place in every collection of materia medica. The slides are by Möller, and are well mounted and authenticated. One object, known as the microscopic marvel, attracted much attention from its extreme beauty. It consisted of a minute bouquet, the flowers being made of diatoms and different coloured scales from butterflies' wings. Another most beautiful slide, which is quite a triumph of microscopical skill, consists of 100 valves of diatoms, each in the centre of a minute square, which contains its name and the authority for the name, the whole of the hundred squares occupying only a space that could be covered with a sweet-pea seed. The names and squares are micro-photographed first, and then the diatoms put in position by manual dexterity.

Other objects of interest in this room were a large yellow-tinted Cape diamond of 66 carats, valued at £20,000, and minerals found with diamonds, exhibited by Professor Tennant; a mass of crystallized gold, exhibited by Mr. W. C. Roberts, Chemist to the Mint, and a picture, by Millais, of the president (Mr. T. H. Hills), which was generously presented by him on the same day to the Council of the Pharmaceutical Society.

In the laboratory of the Society were exhibited M. Orsat's apparatus for the analysis of gases, which is so constructed as to be available for use by any one of ordinary intelligence, and to furnish ready and comparatively trustworthy indications. It is especially intended for commercial purposes, and would probably be found useful in sulphuric acid manufactories, sugar works, etc.

Mr. Fletcher, of Warrington, also exhibited his well known portable gas furnaces, adapted either for a high or for so low a temperature as to enable the operator to dispense with a sand bath; also a muffle furnace for analytical purposes, and for burning in photo-enamels.

Mr. R. H. Davies, F.C.S., demonstrator in the laboratories of the Pharmaceutical Society, during the evening exhibited and explained Mr. Crooke's very interesting experiments, showing the attractive and repellent properties of light and radiant heat, Mr. Crooke's own apparatus being kindly lent for the purpose. The apparatus consisted of three globes, in each of which a piece of pith was attached to a slender rod suspended by a hair. When the heat of a candle was applied to the outside of the first globe, which had been exhausted of air, the pith was repelled, but attracted when a freezing mixture was applied. In the second globe, from which the air had not been removed, when the same agents were applied, exactly opposite results ensued. In the third globe, from which the air had been removed to a certain degree only, no movement of the pith occurred.

In the Museum, Mr. Geraut showed his complete and capacious soda-water machine in action, and exhibited a number of improved gazogenes, syphons, and similar apparatus.

Parliamentary and Law Proceedings.

The Charge against a Chemist and Druggist of Adulterating Quinine.

On Tuesday, at Burslem, Staffordshire Potteries, before Mr. H. C. Greenwood, stipendiary magistrate, Mr. W. S. Pearson, chemist and druggist, Kidsgrove, was summoned for having sold, as unadulterated, some quinine which was adulterated with sulphate of cinchonine. Mr. Fulford, barrister, instructed by the Clerk of the Peace for Staffordshire, appeared in support of the charge, and Mr. F. W. Tomkinson, solicitor, for the defence. The case was heard at great length at Tunstall, on the 2nd of July, when the certificate of Mr. Scott, county analyst, was put in as evidence, and Mr. Scott was called to state that the quinine, which was purchased from the defendant on the 18th of June, "was largely adulterated with sulphate of cinchonine, an alkaloid comparatively valueless for those or most of those purposes for which quinine is specially employed." The defendant had sent a portion of quinine (which he said was from the same bottle as that which was sold to the county inspector, and analysed by the county analyst) to Dr. Attfield, of London, who, in giving evidence, declared that it was pure quinine. The stipendiary magistrate consequently directed that that which had been retained by Mr. Knight, the inspector, should, for his (Mr. Greenwood's) satisfaction, be forwarded to Dr. Paul for analysis, the case being adjourned in consequence. Mr. Thistlethwaite, magistrate's clerk, having read over the charge,

Mr. Fulford said: I wish to make one remark, and only one remark, in this case, for the purpose or calling your attention to the evidence for the defence before you give your decision. You will remember that the defence was that the sample of quinine sent to Dr. Attfield, for analysis, was from the same bottle as that which was analysed by Mr. Scott, the county analyst, and which had been purchased from Mr. Pearson, by the inspector. When you take into consideration the certificates of Dr. Paul and Mr. Scott, you can scarcely conclude that they analysed samples of the same article as that which was sent to Dr. Attfield. The defence was——

Mr. Tomkinson: I object to the learned counsel proceeding to discuss the question.

Mr. Greenwood: Dr. Paul's certificate is simply for my own guidance. You are supposed not to have seen it.

Mr. Tomkinson: It is only for your worship to give judgment in the case. My friend is out of place in making a remark. He has no right to say anything.

Mr. Greenwood: I don't think you can say anything, Mr. Fulford.

Mr. Fulford: Ignorance was the defence set up, and——

Mr. Tomkinson: The learned counsel wants to make out we do not know what we are doing. I think we have shown that we do know what we are doing.

Mr. Greenwood: The object of the adjournment was to have a third analysis. Owing to the totally different opinions of Mr. Scott and Dr. Attfield, I ordered an analysis to be made by Dr. Paul to enable me to come to a proper decision. A portion of the sample purchased by Mr. Knight, which he retained in his possession up to the hearing of the case at Tunstall, was sent to Dr. Paul, and I have received his certificate, which altogether confirms the certificate of Mr. Scott. In one respect all the three analysts—Mr. Scott, Dr. Paul, and Dr. Attfield—agree; and that is in saying, that if more than 1 per cent. of cinchonine were found in quinine it must have been added, and must be an adulteration. Dr. Attfield said what he analysed was perfectly pure quinine. Mr. Scott said he analysed a portion of the sample purchased from the defendant by Mr. Knight, and it was adulterated with cinchonine to the extent of 10 per cent. Upon those statements being made, I ordered the remainder of the sample purchased from the defendant, to be analysed by Dr. Paul, who agreed with Mr. Scott. I feel bound to say this case is similar in all respects to that of Pendleton's, wherein the article analysed by Mr. Scott was not of the same quality which the defendant got analysed by a chemist of his own selection. In the case of the analysis of Dr. Paul, it singularly confirms that of Mr. Scott; for, whereas the amount of adulteration was stated by Mr. Scott as 10 per cent., Dr. Paul said it was from 8 to 15 per cent. That suggests that the cinchonine had been added, and was not correctly mixed with the quinine; the portion sent to Dr. Paul being more seriously adulterated than that analysed by Mr. Scott. I cannot, therefore, help thinking, that as the article analysed by Mr. Scott was, without doubt, adulterated, the article sent to Dr. Attfield was so sent for the purpose of misleading the court. I am sorry to say I cannot help feeling this; and under these circumstances I shall have to impose a fine; but as it was not stated that the adulteration was injurious to health——

Mr. Fulford: I beg your pardon. It is "injurious," according to the statute. The statute makes any mixture of a drug, which is sold as a particular drug, nominally "injurious," though it may not be really injurious.

Mr. Greenwood: That was explained by Dr. Attfield, who, I think, if I remember rightly, said that 4 per cent. of quinine was equal to 5 per cent. of cinchonine.

Mr. Fulford: Making a difference in the price.

Mr. Tomkinson: The benefit to us would be about a farthing on the quantity sold, or even less than a farthing.

Mr. Greenwood: I feel it is my duty to fine the defendant 20s. and costs.

Mr. Tomkinson: Now the judgment is given in the case, I think it only right to say I shall advise Mr. Pearson, whom Mr. Knight admits to be one of the most respectable tradesmen in the district, to take proceedings against the persons from whom he purchased his drugs. He sold the quinine as he received it.

Mr. Greenwood: It is for you to take your own course. My only duty is to deal with the case as it comes before me, and that I have done.

Sale of Laudanum by a Grocer.

An inquest was held at Goole, Yorkshire, on Tuesday, July 21st, before Dr. Graham, Coroner, on the body of an infant named Elizabeth Stephenson, aged nine months. It was stated that the child was taken ill on the previous Friday, and the mother obtained a mixture for it from Mr. Ekam, grocer, the same evening. The child died on Sunday morning.

Mr. Ekam showed the Coroner the recipe for the medicine, from which it appeared that a pint of it contained two ounces of syrup of poppies and five drachms of laudanum.

The Coroner pointed out that the evidence showed the child had taken a teaspoonful of the mixture, or three drops of laudanum, without counting what was in the syrup of poppies, the proportion of which varied. He said it was certainly a dangerous mixture to sell for children.

Mr. East (assistant to Mr. Morris, surgeon), who saw the child after death, said he was of opinion that the child died from natural causes. He did not think the dose of the mixture given on Friday had caused the child's death on Sunday. At the same time the mixture was a very improper one for children.

The Coroner in summing up said that the law ought to put a stop to the sale of these medicines by unqualified persons. He considered that to this cause was attributable, in great measure, the excessive mortality amongst children.

The jury returned a verdict of "Death from natural causes," adding an expression of opinion that the medicine was not a proper one to be sold. At their request, Mr. Ekam was called in, and cautioned by the Coroner.—*Hull News.*

Alleged Attempt to Poison a Child.

Maria Shehan, 20, a servant, was on Monday charged on remand, at the Highgate Police Court, with administering poison to her illegitimate child.

The accused had been remanded for the additional evidence of Mr. Pitman, a surgeon, who had on the last examination been able to give but partial testimony as to the poisonous ingredient said to have been mixed with the milk given to the child of the accused. Mr. Pitman now deposed that when the infant was brought to him by a nurse, to whom the mother had confided it, it was suffering apparently from some irritant poison. Witness had since analysed the milk left in the bottle, and found that it contained bicarbonate of soda in considerable quantity. In one dose this would not be fatal, though it would upset the stomach. The analysis showed that in one ounce of fluid there were 30 grains of bicarbonate of soda. He was not aware that any fatal case of poisoning had arisen from bicarbonate of soda, but it was undoubtedly an irritant poison. He did not think what was said to be the whole contents of the bottle while in prisoner's possession—about six ounces of fluid—would have destroyed life in one dose. Repeated doses would injure the coats of the stomach. It was not deadly poison, but it was an irritant. It would not prove fatal in the proportion given unless repeated doses were given at short intervals.

It was submitted there was not sufficient evidence on which to commit the prisoner, but the magistrates, after receiving some further formal evidence, remanded the prisoner for the attendance of Mr. Bodkin, who first heard the case.—*Daily Telegraph.*

Correspondence.

*** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

J. A. C. B.—The next examination in London, which will be held in October, will be conducted according to the new regulations.

"*Sussex.*"—Syrupus papaveris is in some districts sold as Syrupus corum, "corum" being possibly a corruption of "Diacodion."

J. H. Thring.—We think the precipitate will be principally pure quinia, separated by the slight alkalinity of the salts, and probably mixed with a little oxide of iron, as aqueous solutions of commercial citrate of iron and quinine deposit a little of this when kept a short time.

[We are compelled by want of space to postpone notices of several communications.]

Communications, Letters, etc., have been received from Mr. J. Barker, Mr. Cardell, Mr. Bennett, Mr. Hill, Mr. Smith, Mr. Druce, Mr. Bartholomew, Mr. White, Mr. Long, Mr. Hustwick, Mr. Balcomb, Mr. Carent, Mr. Shenstone, Mrs. Hart, T. P. B., W. R., F. C., A. J. R., F. A. B., R. M., W. W. W., X. Y. Z., G. B. "Young Man from Country," "Apron."

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ENGLISH AND AMERICAN HONOURS TO PRIESTLEY.

IF it be true of individual gratitude that it is sometimes a lively sense of favours to come, it is equally true of public gratitude that it is generally a tardy recognition of favours received. It appears to be the present fashion to scrutinize the benefits conferred upon the world in a past century, and every now and then to give vent to the accumulated gratitude of a hundred years in a centennial festival, or a statue, or both. One good result of this apparent negligence is, that the "judgment of posterity," so often appealed to, comes into play, and that many men who were opposed, despised, or ignored by their contemporaries are thus brought into the front rank, to the displacement of others whose reputation was temporarily inflated by circumstances. This is eminently true of the man, JOSEPH PRIESTLEY, who, one hundred years since, was the first to discover oxygen; who, a few years afterwards withdrew from the violence of his fellow townsmen and the ostentatious neglect of his scientific brethren to seek a home beyond the Atlantic; though the England of to-day points with pride to his birthplace as America does to his grave.

As was fitting, it is in Birmingham, where intolerant ignorance reduced PRIESTLEY's house to ashes that his statue is now set up in marble. Professor HUXLEY pronounced the *éloge* of the chemist, philosopher, politician, and theologian, and no one could have done it more appropriately It is chiefly in the first of these capacities that the world of to-day is influenced by PRIESTLEY; although there appears to have been sufficient *odium theologicum* displayed at Birmingham—by abstention on one side and castigation on the other—to suggest that it would be necessary to adopt the recent example of Ireland, and hold millennial celebrations, if they are to be conducted quite dispassionately.

It is not without interest to pharmacists to note that the details of the discovery of oxygen might almost be described in the words of one of the present Pharmacopœia tests. The apparatus consisted of of a phial filled with mercury, into which PRIESTLEY had introduced a substance then called "mercurius calcinatus per se," now known as red precipitate. This substance floated upon the top, and was exposed to the sun's rays, concentrated by means of a lens. Let him continue the story in his own words—

"I presently found that, by means of this lens, air was expelled from it very readily. Having got about three or four times as much as the bulk of my materials, I admitted water to it, and found that it was not imbibed by it; but what surprised me more than I can express was that a candle burned in this air with a remarkably vigorous flame, very much like that enlarged flame in which a candle burns in nitrous air, exposed to iron or liver of sulphur; but as I had got nothing like this remarkable appearance from any kind of air besides this particular modification of nitrous air, and I knew no nitrous acid was used in the preparation of *mercurius calcinatus*, I was utterly at a loss how to account for it. In this case also, though I did not give sufficient attention to the circumstances at that time, the flame of the candle, besides being larger, burned with more splendour and heat than in that species of nitrous air; and a piece of red-hot wood sparkled in it exactly like paper dipped in a solution of nitre, and it consumed very fast—an experiment which I had never thought of trying with nitrous air."

Simultaneously with the celebration in Birmingham, on the 1st of the present month, the centenary of the discovery of oxygen—or "oxygen day" as it has been named—was commemorated in the United States by a gathering of chemists and other scientific men at Northumberland, Pennsylvania, within sight of which town is PRIESTLEY's grave. We learn from newspapers just received that the proceedings commenced on the 31st July, under the presidency of Professor C. F. CHANDLER, and lasted during two days. Among the incidents of the meeting were an exhibition of relics associated with PRIESTLEY's philosophical labours; an address on his life and labours, by Professor CROFT, of Toronto; a review of a century's progress in theoretical chemistry, by Professor STERRY HUNT, and another of a century's progress in industrial chemistry, by Professor J. LAWRENCE SMITH; whilst Professor SILLIMAN read an essay on American Contributions to Chemistry. A "memorial address" was delivered in the cemetery by Dr. HENRY COPPEE.

The meeting at Northumberland was formally adjourned to the 1st of August, 1974. What science may accomplish before that day arrives none can guess; what is possible is suggested by the words of Professor HUXLEY, that JOSEPH PRIESTLEY's time was "before the day of LAPLACE, before the day of DAVY, before the day of FARADAY, before the day of HUTTON, in geology; and that he was contemporaneous with the time when LINNÆUS was bringing botany from chaos into order."

THE BRITISH ASSOCIATION.

ON another page will be found the address of Professor TYNDALL to the members of the British Association, at Belfast, on Wednesday evening. As an eloquent exposition of the antiquity of the doctrine of atoms and summary of the arguments in favour of the more modern theory of evolution, it will be read with interest, but towards the solution of the problem of the origin of life it cannot be said to contribute much. "Though Dr. TYNDALL may "prolong the vision backward across the boundary "of the experimental evidence, and discern in that "Matter which we in our ignorance, and notwith- "standing our professed reverence for its Creator, "have hitherto covered with opprobrium, the promise "and potency of every form of Life," he will still be confronted by the question, how came that Life there?

It is reported that the number of members in attendance at the meeting of the Association is about fourteen hundred, and that, notwithstanding the promise that there would be no increase in the ordinary charges for accomodation, the demands range from ten to twenty shillings per night. This obnoxious extortion is now becoming so systematic as to constitute a serious impediment to that promotion of science which is the aim of the British Association, and we think it would be worthy of its leaders to endeavour to put a stop to the practice.

THE INTERNATIONAL PHARMACEUTICAL CONGRESS AT ST. PETERSBURGH.

THE fourth international congress of pharmaceutists was commenced at St. Petersburgh, on Friday, the 14th inst., by an address from Mr. Privy Councillor TRAPP, Director of the Pharmaceutical Society in that city. Twelve different Societies were represented by seventeen delegates. Unfortunately, the delegates from the German General Pharmaceutical Society, were, at the last moment, prevented from attending through a convocation of a pharmaceutical *enquête-commission* by the German Chancellorate.

After being reminded by Mr. TRAPP that the principle followed in former Congresses was to choose an apothecary in actual practice as president, the Congress proceeded to the election of officers, with the following result:—President of the Congress, Dr. v. WALDHEIM, of Vienna (Austrian Pharmaceutical Society); Vice-Presidents, Messrs. MADSEN, of Copenhagen (Danish Pharmaceutical Society), and TRAPP, of St. Petersburgh. The Secretaries chosen were Dr. MÉHU (Société de Pharmacie, Paris); Mr. F. SUTTON (Pharmaceutical Society of Great Britain); Mr. JANAUSCHECK (Pharmaceutical Society, Prague); and Mr. RENNARD (Pharmaceutical Society, St. Petersburgh).

It was unanimously decided that German should be the "business language," and that Question 3 in the programme (Is it necessary that a professorship of pharmacy should be held only by a pharmacist?) should be forthwith discussed. Questions 1 (the responsibility of assistants), 2 (committee of revision) and 4 (International Pharmacopœia), were remitted to the previous consideration of committees. After the discussion had concluded it was resolved unanimously, that "It is very desirable that the professorships of pharmacy should be held by pharmaceutists, and it is further desirable that, where circumstances will allow, there should be two chairs, one for materia medica and one for pharmaceutical chemistry."

We hope to be able next week to give a further report of the proceedings of the Congress.

THE Meeting of the American Pharmaceutrical Association for 1874 will be held in the city of Louisville, Kentucky, on Tuesday, 8th September, under the presidency of Mr. JOHN F. HANCOCK, of Baltimore.

THE statement on p. 139 of our last issue, respecting the portrait by MILLAIS was incorrect. The picture in question was kindly lent for the occasion by the President.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE

(*Continued from page* 138.)

On the Conference re-assembling, Professor ATTFIELD read the following paper by Professor Flückiger:—

ON THE CHEMISTRY OF ELEMI.

BY PROFESSOR FLÜCKIGER,

of Strassburg, Hon. Member of the Pharmaceutical Society of Great Britain.

Towards the year 1820, George Samuel Perrottet, a Swiss botanist, then a collector for the Jardin des Plantes at Paris, brought to Lausanne, from Manilla, a specimen of the resin of a tree known in the Philippines as *Arbol-a-brea*, i.e., *Pitch-tree*. The tree is thus called on account of its abundant resin, which is much used in the Philippines for the caulking of boats, for torches, and also in medicine, but the resin does not appear to have been at that time collected for exportation.

At Lausanne this resin was examined by the distinguished chemist, Samuel Baup, who found it to have "*un peu de ressemblance avec la résine élémi.*" It is, in fact, nothing else than that kind of elemi which is now largely exported from Manilla, and has long superseded the other sorts of this drug, which had successively made their appearance in the European market. I am not aware of the exact period at which Manilla elemi first reached Europe in large quantities, yet Baup, in his paper, "*Sur les Résines de l'Arbol-a-brea et de l'Elémi,*" contained in the *Journal de Pharmacie et de Chimie*, vol. xx. (1851), pp. 321-332, was not of the opinion that Perrottet's specimen agreed with elemi as then found in commerce. We may, however, presume that Baup was no longer thoroughly familiar with the drug market, since he had in 1823 already retired from practical pharmacy. But there is another fact which seems to me in favour of Baup's opinion that the elemi of his time was not that from Manilla. The essential oil of elemi was found, in 1841, by H. Sainte-Claire Deville,* to be strongly levogyre and to yield easily a crystallized compound, $C_{10}H_{16}+2\,HCl$, whereas elemi of Manilla, which I have repeatedly examined, affords a *dextrogyre* oil, incapable of yielding this solid hydrochlorate. This, I think, is sufficient to show that in 1841 Manilla elemi was not yet the prevalent sort, or, at least, that Deville's drug was not such. I had the opportunity, on the other hand, of examining a small fragment of the very substance which came into Baup's possession,† and think it agrees with the Manilla elemi of the present market, only differing from the latter in being *black*. This is due to the smoke of the torches, which were applied to the tree in order to promote the outflowing of the oleo-resin. As to the *Arbol-a-brea*, and its botanical characters, nothing precise and satisfactory has yet been made out.

Among the substances isolated from Manilla elemi by Baup, I shall notice now only those *soluble in water*, which he termed *Bryoidin* and *Breïdin*. He obtained them in the following way:—As elemi consists chiefly of essential oil, a crystallizable resin sparingly soluble in cold alcohol, and an amorphous resin easily removable by the latter liquid, Baup first boiled the drug with alcohol of 90-95 per cent. On cooling, the colourless crystallizable resin (*la sous-résine*) is deposited, and may be washed with cold alcohol of 85 per cent. These crystals were called *amyrin*, because at that time a Brazilian tree, *Amyris elemifera* Linn., was thought to furnish the elemi of commerce; and Baup regarded the amyrin

* *Comptes Rendus*, vol. xii. (1841) p. 184.

† I am indebted for it to Mr. Roux, late pharmacien of Nyon, Lake of Geneva, the author of '*Notice biographique sur Samuel Baup, chimiste*' in the *Schweizerische Zeitschrift für Pharmacie*, December, 1862, Appendix.

obtained from the latter as identical with the crystallizable part of the oleo-resin from the Philippines. The alcoholic solution, separated from the amyrin, was then submitted to distillation, in order to drive over the essential oil and the alcohol. The residue in the still consisted of the soft amorphous brownish resin, and a turbid, aqueous liquid. The latter was decanted, the resin repeatedly washed with alcohol of only 50 per cent. (about ·916 sp. gr.); the mixed liquids were then evaporated, to deprive them of essential oil and alcohol. Finally, a brown, oily aromatic* mass separated and sunk, while, upon cooling, delicate, white needle-shaped or moss-like crystals made their appearance, and were termed by Baup *Bryoidin*. The liquid, on further evaporation, separated into two layers, of which the heavier proved to contain chloride of potassium and other inorganic salts; the upper thickish layer (resembling the before-mentioned "aromatic" mass) afforded, when boiled with a little water, some more bryoidin. These latter crops of crystals, after repeated purification by water, finally gave crystals of a substance which, according to Baup, did not agree with bryoidin, and he therefore distinguished it as *Breïdin*.

The characters of the two substances are thus described by Baup—*Bryoidin* is a little *bitterish* and somewhat acrid; its silky crystals may be sublimed between two watch-glasses, when they form moss-like tufts. The crystals melt at 135° C.; they require, at 10°, 350 parts of water for solution. This solution is neutral; acetate of lead, either neutral or basic, produces in it a precipitate. Bryoidin is much more abundantly soluble in alcohol, ether, essential or fatty oils, or acetic acid. With concentrated sulphuric acid it assumes a red colour.

Breïdin, according to Baup, is in prisms, exhibiting angles of 102° and 78°, and terminating in four-sided pyramids; 260 parts of water, at 10°, are sufficient to dissolve one part of breïdin; and the solution is precipitated by basic acetate of lead. Breïdin is freely soluble in alcohol, not much so in ether. The crystals melt at a little over 100° C., and are volatile, like those of bryoidin. These characters are, it will be observed, no very well marked differences between the two substances, and I believe that they are not really different at all.

I am not aware that any chemist attempted to repeat Baup's observations until last winter, when my friend, Mr. Hanbury, caused to be distilled a quantity of Manilla elemi, and took the opportunity of examining the watery liquor remaining in the still for bryoidin. He succeeded perfectly in obtaining this substance in colourless crystals, by a method which we have described in the work on drugs which is about to appear under our joint authorship. Since those observations were printed, I have carried on the experiments a little further, and, after various trials, have adopted the following as the best process for extracting bryoidin, as it appeared evident that weak alcohol is a good solvent of bryoidin. I placed four kilogrammes of elemi in a copper still, and had it gently warmed in the water-bath for a day or two, with twenty kilogrammes of alcohol of ·972 sp. gr., that is to say, a weak spirit containing but 22 per cent. of alcohol. The essential oil which came over was separated, and the spirit of wine, from which it was removed, was returned to the still. After this operation had been sufficiently carried on, the still contained a solid resin, and a weak alcoholic solution, *A*. The resin was now boiled for a day with much water, and afforded another portion of essential oil, which I found to be dextrogyre, like that obtained by means of dilute alcohol.† The water in the still (*B*) was separated, and the resin warmed with about twelve kilogrammes of alcohol, sp. gr. ·830, and two kilogrammes of water. After cooling, the liquid (*C*) contained the amorphous resin, the other resin being deposited in white crystals, agreeing with Baup's *Amyrin*.

In order to get bryoidin, I submitted the liquid *A* to distillation, and subsequently evaporated the merely aqueous liquid from which the alcohol had been abstracted. During the evaporation a very small amount of crystallized amyrin, contaminated with a trace of the amorphous resin, first separated. The weakness of the alcohol which had been used prevented any larger amount of resin being dissolved. It is important not to evaporate at once all the liquid *A*, and especially not to allow it to boil. After having tried the preparation of bryoidin in different ways, I came to the conclusion that the best plan is to evaporate on the water-bath small successive portions of the liquid until they begin to yield crystals of bryoidin floating on the surface. The liquid should then be allowed to repose for 24 hours, when the bryoidin can be removed from it, the mother liquid being reserved for further evaporation. By heating the solutions to full ebullition, bryoidin itself would evaporate to some extent. By gradual evaporation as just described, it is obtained at once in a state of approximative purity. But if the concentration of the liquid is carried on without separating the crystals as soon as they appear, the final purification of the latter becomes difficult by reason of another principle occurring in elemi. This is a brown *bitter substance* which is more abundantly soluble in water than bryoidin. In the treatment of elemi just recommended, this bitter substance is contained in the aqueous liquid *A*, together with bryoidin. If this liquid is concentrated, brown drops of the bitter substance separate at a certain moment, and form a thickish resinoid deposit. Now, if the crystals of bryoidin have not been taken out of the liquid, they will be enveloped and thrown down by this resinoid matter, and can only be recovered therefrom with some difficulty.

As to the liquid *B*, I have evaporated it with the same care, and got from it a little bryoidin, yet scarcely enough to repay the trouble. The same must be said with reference to the solution *C*; if this is deprived of alcohol, the amorphous resin separates, but the aqueous liquid proves poor in bryoidin. As a rule, I cannot therefore recommend to include the liquids *B* and *C* in the process. The whole amount of bryoidin which I have been able to remove from elemi scarcely exceeds ·3 per cent., that is to say, of nearly pure bryoidin; its appearance in the mother-liquors is much more promising, owing to its extreme lightness and flocculent aspect.

To purify bryoidin, it must be repeatedly re-crystallized from boiling alcohol of 22 per cent. At first the solutions are slightly brownish, a little turbid, bitterish in taste, and yield precipitates with tannic acid or with neutral acetate of lead. All this is but due to traces of the bitter principle, for after several re-crystallizations, using also a little charcoal, the solutions become colourless, perfectly clear, weaker in taste, and miscible with either neutral or basic acetate of lead, without being precipitated. The final yield of pure bryoidin is unfortunately much reduced by purification. Instead of the voluminous moss-like tufts obtained in the earlier stages of the operation, bryoidin may be at last got in brilliant prisms by allowing the solution to evaporate spontaneously. This is, I think, the substance that Baup called *Breïdin*. I have been unable to find any real difference between it and my bryoidin; under the microscope the prisms display a remarkable tendency to split longitudinally, which is well in accordance with the usual moss-like growth of the substance. The latter shows under the microscope very long, soft, thread-like crystals. In polarized light the crystals are seen to be refractive; they consequently do *not* belong to the cubic system.

There can be no doubt that Baup's observations are correct; yet it is evident that some of the properties he assigned to bryoidin apply to the imperfectly purified substance; his investigation must nevertheless be com-

* Its peculiar smell is not at all that of the original essential oil of elemi.

† See *Pharmacog.*, p. 132, where we already stated another sample of oil of elemi to deviate also to the right hand.

mended as a remarkably successful one,* when it is considered that he had but very little of the "*Resin of the arbol-a-brea*" at his command.

At 135°—136° C., bryoidin melts, and at a more elevated temperature can easily be sublimed; it volatilizes in fact below 100°, so that very nice tufts are produced by exposing it for some days to the heat of the water-bath only. The crystals are anhydrous, giving off no water, either over sulphuric acid or at 100° C. They are readily soluble in alcohol, bisulphide of carbon, chloroform, ether, acetic acid, also in essential oil of elemi or glycerin; their solubility is not increased by the presence of alkalies or acids. Cold concentrated sulphuric acid slowly dissolves bryoidin, and assumes, when warmed with it, a reddish hue. By cold nitric acid, bryoidin is liquefied and forms brownish drops not soluble in the acid.

Bryoidin purified by repeated re-crystallization and sublimation assumes a fine red colour if it is exposed to dry hydrochloric gas; it is subsequently liquefied, and turns violet, then a most brilliant *blue*, and lastly an intense *green* being developed. The colours are permanent for several days; the liquids are soluble in chloroform, yet I have not succeeded in getting a solid compound by the hydrochloric treatment. These reactions are not at all displayed by amyrin, the before-mentioned crystallizable resin of elemi. As to the amorphous part of the drug, it turns only a little reddish by hydrochloric gas, probably on account of a trace of bryoidin which it obstinately retains. The essential oil of elemi, if saturated with anhydrous hydrochloric gas, assumes a dark violet tint.

I have failed in ascertaining satisfactorily the solubility of bryoidin in water. I found one part of it to be contained in 384 parts of a solution saturated at 28—30° C.; but another solution prepared at 25° C. afforded one part of bryoidin in 492 parts. A solution prepared by boiling water with bryoidin in excess, and then allowed to remain for a week that the crystals should deposit, yielded one part in 523 parts of the solution. In every case the solutions were carefully concentrated at a temperature not exceeding about 70° C., and then fully evaporated over sulphuric acid. The loss of bryoidin to any appreciable amount was thus avoided. I think the discrepancies are due to the formation of supersaturated solutions.†

In boiling water, bryoidin is not much more soluble than in cold, for 200 parts of it are able to dissolve but one of bryoidin, of alcohol 22 per cent. (0·972 sp. gr. at 15° C.) 147 parts dissolve one of bryoidin at 28° C., yet much more when warmed. The solutions taste aromatic.

The analysis of bryoidin afforded, on an average, carbon, 74·21 per cent., and hydrogen, 11·52; these numbers may refer to the formula, $C_{20}H_{38}O_3$, namely:—

				Analysis.
20 C	240	equal to	73·62	74·21
38 H	38	„	11·65	11·52
3 O	48	„	14·73	14·27
	326		100·00	100·00

Thus bryoidin may be regarded as a hydrate of the essential oil contained in elemi, that is to say, as answering to the composition—$2(C_{10}H_{16}) + 3\,H_2O$; yet it must be borne in mind that it contains no water of crystallization. By submitting it to sublimation it undergoes no alteration, as already proved by its melting-point remaining the same as before, namely, 135°—136° C. This view is supported by the composition of the amyrin, which I believe to answer to the formula, $C_{20}H_{34}O$. This substance might be regarded as $C_{20}H_{32} + H_2O$, and bryoidin, $C_{20}H_{32} + 3\,H_2O$; there can be but little doubt that elemi will also afford the intermediate compound, $C_{20}H_{32} + 2\,H_2O$.

In its general behaviour, bryoidin resembles terpin, $C_{10}H_{16} + 3\,H_2O$, the crystallized hydrate of essential oil of turpentine, or rather of the substance $C_{10}H_{20}O_2$, which is obtained when terpin, by melting, parts with H_2O, that is, losing 9·47 per cent. This anhydrous terpin melts at 150°, and is soluble in 200 parts of cold, or 22 parts of boiling water, and freely soluble in all alcoholic or ethereal liquids. There are, however, great differences between bryoidin and terpin. By boiling the latter with very little dilute sulphuric acid, *Terpinol*, $C_{20}H_{34}O$, a fragrant liquid, is formed. No such thing is produced with bryoidin. Nor is terpin coloured by hydrochloric gas. Again, if bryoidin is brought into contact with acetyl chloride, a very energetic action and effervescence takes place, whereas terpin quietly dissolves, so does likewise amyrin.

Bryoidin and terpin agree inasmuch as they are volatile and, in solution, devoid of rotatory power, although both these compounds are derived from essential oils, $C_{10}H_{16}$, which possess that optical characteristic.

It would appear possible that the constituents of elemi may be allied thus:—

Essential oil	$C_{10}H_{16}$
Crystallized resin (elemin or amyrin)	$2(C_{10}H_{16}) + H_2O$
Amorphous resin (?)	$2(C_{10}H_{16}) + 2\,H_2O$
Bryoidin	$2(C_{10}H_{16}) + 3\,H_2O$

But further researches are needed to prove the correctness of this suggestion.

The *bitter substance* already mentioned is by no means abundant in elemi, though it appears to be present to a somewhat larger amount than bryoidin. I have in vain endeavoured to isolate from it a well-defined compound. The resinoid brown mass, which at last separates from the concentrated aqueous solutions, *A* or *C*, has a very intensely bitter, and at the same time aromatic, non-acrid taste. The latter reminds one of orange peel, and is certainly due to the substance itself, not to essential oil of elemi. An entirely different and strong odour is evolved by the bitter mass, if it is boiled with dilute sulphuric, nitric, or hydrochloric acid. In this case, the odour is somewhat suggestive of melon, caraway, or especially of a fresh terebinthinous varnish. By this treatment with acids, the bitter taste disappears; I have not been able to ascertain whether sugar is, at the same time, produced, because the brown bitter mass would appear already to contain some sugar, seeing that it is capable, to a small extent, of reducing alkaline tartrate of copper. If the bitter mass is warmed with a moderately concentrated mineral acid, it assumes an intense violet or blue colour, and is also coloured in the same way by dry hydrochloric gas. From a solution in dilute alcohol, the bitter semi-fluid mass is partially thrown down by absolute alcohol; yet this precipitate proves to be by no means a pure substance. Its aqueous solution is partly precipitated by tannic acid or by neutral acetate of lead, another portion remaining unaltered in solution. I have failed in removing from the bitter substance the inorganic matters which, as shown by incineration, it largely contains. Baup was well aware of the large amount of mineral substances occurring in the extracts of elemi; in fact they appear to constitute the chief amount of the brown bitter deposit.

The PRESIDENT: This paper of Professor Flückiger's is another instance of his laudable zeal in pharmaceutical chemistry. Elemi is a resin now very rarely used, but I think it might often replace to advantage the common resin. We are very glad to hear the chemistry of it, and we must thank Professor Flückiger for so fully investigating it. I beg to propose that you accord to Professor Flückiger a vote of thanks for his paper.

The vote of thanks was carried.

Mr. D. HANBURY: It is rather difficult to follow the

* Like many others due to that zealous man; we may quote, for instance, his valuable contributions to the knowledge of quinine, cinchonine, kinic acid, citric acid, aconitic acid, and equivalent numbers. Baup was born 15th May, 1791, at Vevey, on the Lake of Geneva, and died 9th February, 1862, at Lavaux, not far from the former place. In 1816 he paid a visit to London, and saw Brodie and Brande.

† To this circumstance may be due the remarkable separation of *flocks*, described in our *Pharmacographia*, p. 134.

details in a paper on this subject, and therefore I may perhaps be excused for making a remark with the object of simplifying some of the explanations given. When I prepared the substance on the table, I was not aware of all the facts subsequently discovered by Professor Flückiger. I obtained bryoidin by simply evaporating the watery liquid in the still, after obtaining the essential oil of elemi. In this way, I got colourless crystals, which, by a little special manipulation, were obtained in a state of comparative purity. One of the most interesting characters of bryoidin is the easy way in which it sublimes. If you put a little of it into a watch glass, cover it with a piece of window glass, and then hold it over the flame of a lamp or a candle for a few moments, the substance will collect upon the upper glass in beautiful minute crystals. Professor Flückiger alludes to the curious separation of *flocks* which takes place, and I may perhaps explain what it is. When you obtain a crystallization of bryoidin from water, there is of course a mother liquor left, and when it is poured off and filtered, you have a perfectly clear solution; if you heat this solution, it immediately becomes turbid, and deposits what looks like pieces of white paper or wool. It is a curious circumstance, and occurs, I suppose, through the supersaturation which is alluded to. If you examine this substance, it will be seen to consist of filamentous crystals which do not redissolve either by heating or cooling. With regard to amyrin, that is easily prepared, not only from Manilla elemi, but from other varieties. If you take the elemi of South America or Mexico, and treat it with cold spirit of wine, a white matter separates, which is wonderfully crystalline, and may be readily purified and obtained in distinct crystals: that is amyrin, and, as far as we know, is the same in the elemi from these different sources. It is a beautiful example of crystallizable resin, and one that may be easily investigated by students.

Note on Pomegranate Root-Bark.

BY DR. J. E. DE VRIJ.

Dr. De Vrij then called the attention of the Conference to the different opinions existing as to the efficacy of pomegranate root-bark. Formerly the bark collected in the South of France or in Italy enjoyed a good reputation. Some were of opinion that the real root-bark had gradually been substituted by the stem-bark. Others were of opinion that fresh root-bark ought to be used. Others supposed that only the root-bark grown in India was efficacious. Lately he (Dr. De Vrij) heard in a meeting of physicians the assertion that only the extract made in India from fresh root-bark was efficacious. As he did not agree with all these opinions, and his own opinion was that all *real* root-bark, wherever collected, is efficacious, he used root-bark collected by himself, in 1863, in Java, and consequently eleven years old, to prepare an extract by percolation with cold water. He obtained 40 per cent. of extract, of which 56 pills, each of one grain, were sufficient to expel a tapeworm nine metres long. Every quarter of an hour seven pills were administered, so that the cure was terminated within two hours.

Mr. W. W. Stoddart: Dr. De Vrij's paper is very valuable in two particulars; first of all it is a singular thing that we in Bristol use the pomegranate bark rather extensively, especially with foreigners who come to Bristol, and who use it for dysentery. I should like to ask if the head of the tapeworm came away in the specimen shown?

Dr. De Vrij: Yes, it has been examined.

Mr. W. W. Stoddart: In the second place I have to thank Dr. De Vrij for corroborating my view, which I mentioned here two or three years ago with reference to percolation. You get the powder, mix it up into a thin cream, put it into the percolator, and then put water on the top. When I mentioned that process before, several gentlemen thought it was not practicable, but I am glad to find that Dr. De Vrij agrees with me that it is the proper mode of percolation.

The President: We will not diverge into the question of percolation, which would last us a whole day, but Dr. De Vrij has done very much to rehabilitate the character of this pomegranate root-bark, and we are very thankful to him for his experiments. He says it is not necessary to use the fresh root-bark, although that has been the opinion of many. Only the other day my brother wrote to me with regard to the Italian herbs in popular use, saying that their idea was that the root-bark, to be efficacious, should be fresh; that, however, appears to be erroneous. It is really wonderful to me that the tapeworm should exist at all, considering the number of remedies we have, and it is to be hoped that some day we shall abolish the animal altogether.

Mr. Hanbury: We must remember that it has not its sole habitat in man, but has a variety of homes to which it can retire to get out of the way.

Dr. De Vrij: I should like to know if tapeworm is very frequent in England.

Mr. W. W. Stoddart: It is, very.

Dr. De Vrij: I supposed it must be so, because I notice that you like to eat underdone meat. I have never suffered from tapeworm, but I have known those who do, and who are accustomed to eat underdone meat, and therefore I asked if it was frequent in England.

Mr. W. W. Stoddart: I can speak positively on the subject, because some experiments were made in Bristol some six years ago upon it. I had then an opportunity, from the house in which I lived, of seeing a butcher's shop; and it was there a very frequent occurrence for the boy to cut off bits of meat and eat them raw; and it was also a curious fact that those boys had often suffered very much from tapeworms. Besides that, Dr. Brittan, Physician to the Bristol Infirmary, some time ago took up the subject, and prepared a paper upon it for the Microscopical Society of Bristol. He told his colleague he wished to find out whether eating raw meat induced tapeworm; and on a certain morning he gave to several patients attending the infirmary two drachms of the extract of male fern, and directed them to come back on a certain morning, and if any of them had passed tapeworms, to bring them. The result was that there was something like two buckets full of tapeworms. The patients were principally cooks, and, upon being questioned, they confessed they were in the habit of cutting off bits of raw meat and eating them before cooking. This corroborated Dr. Spencer Cobbold's observation, that tapeworm did not arise so much from eating pork as from eating beef.

Dr. Frazer: The subject of tapeworm has attracted a great deal of attention lately in Ireland, but until I began my researches hardly any tapeworm was known there, except the one derived from the swine, the *Tænia solium*. It was very rarely that one met with the *T. mediocanallata*, and in one case only, and that a very remarkable one, was there found a *Trichocephalus*. The case was remarkable, because the person affected had never been out of the United Kingdom. I may say authoritatively that, if properly used, the *Filix mas* extract is undoubtedly a perfectly effectual cure, though the worm is not expelled alive, but dead.

Mr. Siebold: The comparative merits of the various remedies for tapeworm have been discussed many times, and there seemed as many different opinions expressed. But Dr. Küchenmeister, who is one of the greatest authorities upon the subject, maintains that the Cortex radicis granati is the most successful of all. He also points out that it is very essential that it should be boiled at least six hours in water. Certainly, his experiments show a very remarkable degree of success. Still there is no doubt the male fern and its preparations are exceedingly valuable. But there seems to be a vast difference between the *Filix mas* which we get in our shops, and the fresh article. There is a woman living in Hamburg who advertises to cure every one of tapeworm within twenty-four hours, and she does certainly do so, for I have known scores of cases where people who had made many unsuccessful attempts to discharge the worm went there, and came back completely cured. Her secret is only, I believe, that she cultivates in her own garden the *Filix mas*, and administers it in its fresh state, and I have never heard of a single failure. The worst remedy of all seems to be kousso, which generally causes the worm to be discharged in small pieces without the head.

Mr. Hanbury: I do not understand how the fresh rhizome can be administered.

Mr. Siebold: I believe it is scraped with a knife so as to get a kind of coarse powder or paste, then an infusion is made with warm water, and after the infusion is cool, more powder is stirred in. I cannot state that positively, because all my knowledge is derived from patients, who, of course, are not very familiar with the *modus operandi*. I may add that the dose of male fern given in the Pharmacopœia seems very small; it is only fifteen to thirty minims. I believe one or two drachms are required as a rule to produce a successful result.

(*To be continued.*)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The forty fourth Annual Meeting of the British Association for the Advancement of Science was commenced at Belfast, on Wednesday, by a meeting of the General Committee in the College Library.

Resignation of the Treasurer.

The report of the Council and of the Treasurer were received and adopted. In the former was announced the intention of Mr. Spottiswoode, F.R.S., to resign the office of Treasurer, which he has held for thirteen years. The resignation was received with a general expression of regret, and a vote of thanks to Mr. Spottiswoode was passed upon the motion of Mr. Bramwell, F.R.S., seconded by Dr. Gladstone. It was then agreed to elect Professor Williamson to the vacant office.

Professor Tyndall's Inaugural Address.

A General Meeting was held in the evening, at the Ulster Hall, which was entirely filled. Professor Williamson, the retiring President, briefly introduced his successor, Professor Tyndall, who proceeded to deliver the following address:—

Ladies and Gentlemen,—

An impulse inherent in primeval man turned his thoughts and questionings betimes towards the sources of natural phenomena. The same impulse, inherited and intensified, is the spur of scientific action to-day. Determined by it, by a process of abstraction from experience we form physical theories which lie beyond the pale of experience, but which satisfy the desire of the mind to see every natural occurrence resting upon a cause. In forming their notions of the origin of things, our earliest historic (and doubtless, we might add, our prehistoric) ancestors pursued, as far as their intelligence permitted, the same course. They also fell back upon experience, but with this difference—that the particular experiences which furnished the weft and woof of their theories were drawn, not from the study of nature, but from what lay much closer to them, the observation of men. Their theories accordingly took an anthropomorphic form. To supersensual beings, which, "however potent and invisible, were nothing but a species of human creatures, perhaps raised from among mankind, and retaining all human passions and appetites,"* were handed over the rule and governance of natural phenomena.

Tested by observation and reflection, these early notions failed in the long run to satisfy the more penetrating intellects of our race. Far in the depths of history we find men of exceptional power differentiating themselves from the crowd, rejecting these anthropomorphic notions, and seeking to connect natural phenomena with their physical principles. But long prior to these purer efforts of the understanding the merchant had been abroad, and rendered the philosopher possible; commerce had been developed, wealth amassed, leisure for travel and for speculation secured, while races educated under different conditions, and therefore differently informed and endowed, had been stimulated and sharpened by mutual contact. In those regions where the commercial aristocracy of ancient Greece mingled with its eastern neighbours, the sciences were born, being nurtured and developed by free-thinking and courageous men. The state of things to be displaced may be gathered from a passage of Euripides quoted by Hume. "There is nothing in the world; no glory, no prosperity. The gods toss all into confusion; mix everything with its reverse, that all of us, from our ignorance and uncertainty, may pay them the more worship and reverence." Now, as science demands the radical extirpation of caprice and the absolute reliance upon law in nature, there grew with the growth of scientific notions a desire and determination to sweep from the field of theory this mob of gods and demons, and to place natural phenomena on a basis more congruent with themselves.

The problem which had been previously approached from above was now attacked from below; theoretic effort passed from the super- to the sub-sensible. It was felt that to construct the universe in idea it was necessary to have some notion of its constituent parts—of what Lucretius subsequently called the "First Beginnings." Abstracting again from experience, the leaders of scientific speculation reached at length the pregnant doctrine of atoms and molecules, the latest developments of which were set forth with such power and clearness at the last meeting of the British Association. Thought, no doubt, had long hovered about this doctrine before it attained the precision and completeness which it assumed in the mind of Democritus,* a philosopher who may well for a moment arrest our attention. "Few great men," says Lange, in his excellent 'History of Materialism,' a work to the spirit and the letter of which I am equally indebted, "have been so despitefully used by history as Democritus. In the distorted images sent down to us through unscientific traditions there remains of him almost nothing but the name of 'the laughing philosopher,' while figures of immeasurably smaller significance spread themselves at full length before us." Lange speaks of Bacon's high appreciation of Democritus—for ample illustrations of which I am indebted to my excellent friend Mr. Spedding, the learned editor and biographer of Bacon. It is evident, indeed, that Bacon considered Democritus to be a man of weightier metal than either Plato or Aristotle, though their philosophy "was noised and celebrated in the schools, amid the din and pomp of professors." It was not they, but Genseric and Attila and the barbarians, who destroyed the atomic philosophy. "For at a time when all human learning had suffered shipwreck, these planks of Aristotelian and Platonic philosophy, as being of a lighter and more inflated substance, were preserved and came down to us, while things more solid sank and almost passed into oblivion."

The principles enunciated by Democritus reveal his uncompromising antagonism to those who deduced the phenomena of nature from the caprices of the gods. They are briefly these:—1. From nothing comes nothing. Nothing that exists can be destroyed. All changes are due to the combination and separation of molecules. 2. Nothing happens by chance. Every occurrence has its cause, from which it follows by necessity. 3. The only existing things are the atoms and empty space; all else is mere opinion. 4. The atoms are infinite in number, and in-

* Hume, 'Natural History of Religion.'

* Born, 460 B.C.

finitely various in form; they strike together, and the lateral motions and whirlings which thus arise are the beginnings of worlds. 5. The varieties of all things depend upon the varieties of their atoms, in number, size, and aggregation. 6. The soul consists of free, smooth, round atoms, like those of fire. These are the most mobile of all. They interpenetrate the whole body, and in their motions the phenomena of life arise. Thus the atoms of Democritus are individually without sensation; they combine in obedience to mechanical laws; and not only organic forms, but the phenomena of sensation and thought, are also the result of their combination.

That great enigma, "the exquisite adaptation of one part of an organism to another part, and to the conditions of life," more especially the construction of the human body, Democritus made no attempt to solve. Empedocles, a man of more fiery and poetic nature, introduced the notion of love and hate among the atoms to account for their combination and separation. Noticing this gap in the doctrine of Democritus, he struck in with the penetrating thought, linked, however, with some wild speculation, that it lay in the very nature of those combinations which were suited to their ends (in other words, in harmony with their environment) to maintain themselves, while unfit combinations, having no proper habitat, must rapidly disappear. Thus more than two thousand years ago the doctrine of the "survival of the fittest," which in our day, not on the basis of vague conjecture, but of positive knowledge, has been raised to such extraordinary significance, had received at all events partial enunciation.*

Epicurus,† said to be the son of a poor schoolmaster at Samos, is the next dominant figure in the history of the atomic philosophy. He mastered the writings of Democritus, heard lectures in Athens, returned to Samos, and subsequently wandered through various countries. He finally returned to Athens, where he bought a garden, and surrounded himself by pupils, in the midst of whom he lived a pure and serene life, and died a peaceful death. His philosophy was almost identical with that of Democritus; but he never quoted either friend or foe. One main object of Epicurus was to free the world from superstition and the fear of death. Death he treated with indifference. It merely robs us of sensation. As long as we are, death is not; and when death is, we are not. Life has no more evil for him who has made up his mind that it is no evil not to live. He adored the gods, but not in the ordinary fashion. The idea of divine power, properly purified, he thought an elevating one. Still he taught "Not he is godless who rejects the gods of the crowd, but rather he who accepts them." The gods were to him eternal and immortal beings, whose blessedness excluded every thought of care or occupation of any kind. Nature pursues her course in accordance with everlasting laws, the gods never interfering. They haunt

> "The lucid interspace of world and world
> Where never creeps a cloud or moves a wind,
> Nor ever falls the least white star of snow,
> Nor ever lowest roll of thunder moans,
> Nor sound of human sorrow mounts to mar
> Their sacred everlasting calm." ‡

Lange considers the relation of Epicurus to the gods subjective; the indication probably of an ethical requirement of his own nature. We cannot read history with open eyes, or study human nature to its depths, and fail to discern such a requirement. Man never has been, and he never will be, satisfied with the operations and products of the Understanding alone; hence physical science cannot cover all the demands of his nature. But the history of the efforts made to satisfy these demands might be broadly described as a history of errors—the error consisting in ascribing fixity to that which is fluent, which varies as we vary, being gross when we are gross, and becoming, as our capacities widen, more abstract and sublime. On one great point the mind of Epicurus was at peace. He neither sought nor expected, here or hereafter, any personal profit from his relation to the gods. And it is assuredly a fact that loftiness and serenity of thought may be promoted by conceptions which involve no idea of profit of this kind. "Did I not believe," said a great man to me once, "that an Intelligence is at the heart of things, my life on earth would be intolerable." The utterer of these words is not, in my opinion, rendered less noble, but more noble, by the fact that it was the need of ethical harmony here, and not the thought of personal profit hereafter, that prompted his observation.

A century and a half after the death of Epicurus, Lucretius* wrote his great poem, "On the Nature of Things," in which he, a Roman, developed with extraordinary ardour the philosophy of his Greek predecessor. He wishes to win over his friend Memnius to the school of Epicurus; and although he has no rewards in a future life to offer, although his object appears to be a purely negative one, he addresses his friend with the heat of an apostle. His object, like that of his great forerunner, is the destruction of superstition; and considering that men trembled before every natural event as a direct monition from the gods, and that everlasting torture was also in prospect, the freedom aimed at by Lucretius might perhaps be deemed a positive good. "This terror," he says, "and darkness of mind must be dispelled, not by the rays of the sun and glittering shafts of day, but by the aspect and the law of nature." He refutes the notion that anything can come out of nothing, or that that which is once begotten can be recalled to nothing. The first beginnings, the atoms, are indestructible, and into them all things can be dissolved at last. Bodies are partly atoms, and partly combinations of atoms; but the atoms nothing can quench. They are strong in solid singleness, and by their denser combination all things can be closely packed, and exhibit enduring strength. He denies that matter is infinitely divisible. We come at length to the atoms, without which, as an imperishable substratum, all order in the generation and development of things would be destroyed.

The mechanical shock of the atoms being in his view the all-sufficient cause of things, he combats the notion that the constitution of nature has been in any way determined by intelligent design. The interaction of the atoms throughout infinite time rendered all manner of combinations possible. Of these the fit ones persisted, while the unfit ones disappeared. Not after sage deliberation did the atoms station themselves in their right places, nor did they bargain what motions they should assume. From all eternity they have been driven together, and after trying motions and unions of every kind, they fell at length into the arrangements out of which this system of things has been formed. His grand conception of the atoms falling silently through immeasurable ranges of space and time suggested the nebular hypothesis to Kant, its first propounder. "If you will apprehend and keep in mind these things, nature, free at once and rid of her haughty lords, is seen to do all things spontaneously of herself, without the meddling of the gods."†

During the centuries between the first of these three philosophers and the last, the human intellect was active in other fields than theirs. The sophists had run through their career. At Athens had appeared the three men, Socrates, Plato, and Aristotle, whose yoke remains to some extent unbroken to the present hour. Within this period also the School of Alexandria was founded, Euclid

† Monro's translation. In his criticism of this work (Contemporary Review, 1867) Dr. Hayman does not appear to be aware of the really sound and subtile observations on which the reasoning of Lucretius, though erroneous, sometimes rests.

wrote his 'Elements,' and he and others made some advance in optics. Archimedes had propounded the theory of the lever, and the principles of hydrostatics. Pythagoras had made his experiments on the harmonic intervals, while astronomy was immensely enriched by the discoveries of Hipparchus, who was followed by the historically more celebrated Ptolemy. Anatomy had been made the basis of scientific medicine; and it is said by Draper * that vivisection then began. In fact the science of ancient Greece had already cleared the world of the fantastic images of divinities operating capriciously through natural phenomena. It had shaken itself free from that fruitless scrutiny "by the internal light of the mind alone," which had vainly sought to transcend experience and reach a knowledge of ultimate causes. Instead of accidental observation, it had introduced observation with a purpose; instruments were employed to aid the senses; and scientific method was rendered in a great measure complete by the union of Induction and Experiment.

What, then, stopped its victorious advance? Why was the scientific intellect compelled, like an exhausted soil, to lie fallow for nearly two millenniums before it could regather the elements necessary to its fertility and strength? Bacon has already let us know one cause; Whewell ascribes this stationary period to four causes—obscurity of thought, servility, intolerance of disposition, enthusiasm of temper; and he gives striking examples of each.† But these characteristics must have had their causes, which lay in the circumstances of the time. Rome, and the other cities of the Empire, had fallen into moral putrefaction. Christianity had appeared, offering the gospel to the poor, and, by moderation if not asceticism of life, practically protesting against the profligacy of the age. The sufferings of the early Christians and the extraordinary exaltation of mind which enabled them to triumph over the diabolical tortures to which they were subjected ‡, must have left traces not easily effaced. They scorned the earth, in view of that "building of God, that house not made with hands, eternal in the heavens." The Scriptures which ministered to their spiritual needs were also the measure of their Science. When, for example, the celebrated question of antipodes came to be discussed, the Bible was with many the ultimate court of appeal. Augustine, who flourished A.D. 400, would not deny the rotundity of the earth; but he would deny the possible existence of inhabitants at the other side, "because no such race is recorded in Scripture among the descendants of Adam." Archbishop Boniface was shocked at the assumption of a "world of human beings out of the reach of the means of salvation." Thus reined in, Science was not likely to make much progress. Later on the political and theological strife between the Church and civil governments, so powerfully depicted by Draper, must have done much to stifle investigation.

Whewell makes many wise and brave remarks regarding the spirit of the Middle Ages. It was a menial spirit. The seekers after natural knowledge had forsaken that fountain of living waters, the direct appeal to nature by observation and experiment, and had given themselves up to the remanipulation of the notions of their predecessors. It was a time when thought had become abject, and when the acceptance of mere authority led, as it always does in science, to intellectual death. Natural events, instead of being traced to physical, were referred to moral causes; while an exercise of the phantasy, almost as degrading as the spiritualism of the present day, took the place of scientific speculation. Then came the mysticism of the Middle Ages, Magic, Alchemy, the Neo-platonic philosophy, with its visionary though sublime abstractions, which caused men to look with shame upon their own bodies as hindrances to the absorption of the creature in the blessedness of the Creator. Finally came the Scholastic philosophy, a fusion, according to Lange, of the least-mature notions of Aristotle with the Christianity of the West. Intellectual immobility was the result. As a traveller without a compass in a fog may wander long, imagining he is making way, and find himself after hours of toil at his starting-point, so the schoolmen, having tied and untied the same knots, and formed and dissipated the same clouds, found themselves at the end of centuries in their old position.

With regard to the influence wielded by Aristotle in the Middle Ages, and which, though to a less extent, he still wields, I would ask permission to make one remark. When the human mind has achieved greatness and given evidence of extraordinary power in any domain, there is a tendency to credit it with similar power in all other domains. Thus theologians have found comfort and assurance in the thought that Newton dealt with the question of revelation, forgetful of the fact that the very devotion of his powers, through all the best years of his life, to a totally different class of ideas, not to speak of any natural disqualification, tended to render him less, instead of more, competent to deal with theological and historic questions. Goethe, starting from his established greatness as a poet, and indeed from his positive discoveries in Natural History, produced a profound impression among the painters of Germany, when he published his 'Farbenlehre,' in which he endeavoured to overthrow Newton's theory of colours. This theory he deemed so obviously absurd, that he considered its author a charlatan, and attacked him with a corresponding vehemence of language. In the domain of natural history Goethe had made really considerable discoveries; and we have high authority for assuming that, had he devoted himself wholly to that side of science, he might have reached in it an eminence comparable with that which he attained as a poet. In sharpness of observation, in the detection of analogies, however apparently remote, in the classification and organization of facts according to the analogies discerned, Goethe possessed extraordinary powers. These elements of scientific inquiry fall in with the discipline of the poet. But, on the other hand, a mind thus richly endowed in the direction of natural history, may be almost shorn of endowment as regards the more strictly called physical and mechanical sciences. Goethe was in this condition. He could not formulate distinct mechanical conceptions; he could not see the force of mechanical reasoning; and in regions where such reasoning reigns supreme he became a mere *ignis fatuus* to those who followed him.

I have sometimes permitted myself to compare Aristotle with Goethe, to credit the Stagirite with an almost superhuman power of amassing and systematizing facts, but to consider him fatally defective on that side of the mind in respect to which incompleteness has been just ascribed to Goethe. Whewell refers the errors of Aristotle, not to a neglect of facts, but to "a neglect of the idea appropriate to the facts; the idea of Mechanical cause, which is Force, and the substitution of vague or inapplicable notions, involving only relations of space or emotions of wonder." This is doubtless true; but the word "neglect" implies mere intellectual misdirection, whereas in Aristotle, as in Goethe, it was not, I believe, misdirection, but sheer natural incapacity which lay at the root of his mistakes. As a physicist, Aristotle displayed what we should consider some of the worst attributes of a modern physical investigator—indistinctness of ideas, confusion of mind, and a confident use of language, which led to the delusive notion that he had really mastered his subject, while he as yet had failed to grasp even the elements of it. He put words in the place of things, subject in the place of object. He preached Induction without practising it, inverting the

† 'History of the Inductive Sciences,' vol. i.

‡ Depicted with terrible vividness in Renan's 'Antichrist.'

true order of inquiry by passing from the general to the particular, instead of from the particular to the general. He made of the universe a closed sphere, in the centre of which he fixed the earth, proving from general principles, to his own satisfaction and to that of the world for near 2000 years, that no other universe was possible. His notions of motion were entirely unphysical. It was natural or unnatural, better or worse, calm or violent—no real mechanical conception regarding it lying at the bottom of his mind. He affirmed that a vacuum could not exist, and proved that if it did exist motion in it would be impossible. He determined *à priori* how many species of animals must exist, and shows on general principles why animals must have such and such parts. When an eminent contemporary philosopher, who is far removed from errors of this kind, remembers these abuses of the *à priori* method, he will be able to make allowance for the jealousy of physicists as to the acceptance of so-called *à priori* truths. Aristotle's errors of detail were grave and numerous. He affirmed that only in man we had the beating of the heart, that the left side of the body was colder than the right, that men have more teeth than women, and that there is an empty space, not at the front, but at the back of every man's head.

There is one essential quality in physical conceptions which was entirely wanting in those of Aristotle and his followers. I wish it could be expressed by a word untainted by its associations; it signifies a capability of being placed as a coherent picture before the mind. The Germans express the act of picturing by the word *vorstellen*, and the picture they call a *Vorstellung*. We have no word in English which comes nearer to our requirements than *Imagination*, and, taken with its proper limitations, the word answers very well; but, as just intimated, it is tainted by its associations, and therefore objectionable to some minds. Compare, with reference to this capacity of mental presentation, the case of the Aristotelian, who refers the ascent of water in a pump to Nature's abhorrence of a vacuum, with that of Pascal when he proposed to solve the question of atmospheric pressure by the ascent of the Puy de Dome. In the one case the terms of the explanation refuse to fall into place as a physical image; in the other the image is distinct, the fall and rise of the barometer being clearly figured as the balancing of two varying and opposing pressures.

During the drought of the Middle Ages in Christendom, the Arabian intellect, as forcibly shown by Draper, was active. With the intrusion of the Moors into Spain cleanliness, order, learning, and refinement took the place of their opposites. When smitten with disease the Christian peasant resorted to a shrine, the Moorish one to an instructed physician. The Arabs encouraged translations from the Greek philosophers, but not from the Greek poets. They turned in disgust "from the lewdness of our classical mythology, and denounced as an unpardonable blasphemy all connection between the impure Olympian Jove and the Most High God." Draper traces still further than Whewell the Arab elements in our scientific terms, and points out that the under garment of ladies retains to this hour its Arab name. He gives examples of what Arabian men of science accomplished, dwelling particularly on Alhazen, who was the first to correct the Platonic notion that rays of light are emitted by the eye. He discovered atmospheric refraction, and points out that we see the sun and moon after they have set. He explains the enlargement of the sun and moon, and the shortening of the vertical diameters of both these bodies, when near the horizon. He is aware that the atmosphere decreases in density with increase of height, and actually fixes its height at $58\frac{1}{2}$ miles. In the Book of the Balance Wisdom he sets forth the connection between the weight of the atmosphere and its increasing density. He shows that a body will weigh differently in a rare and a dense atmosphere: he considers the force with which plunged bodies rise through heavier media. He understands the doctrine of the centre of gravity, and applies it to the investigation of balances and steelyards. He recognizes gravity as a force, though he falls into the error of making it diminish as the distance, and of making it purely terrestrial. He knows the relation between the velocities, spaces, and times of falling bodies, and has distinct ideas of capillary attraction. He improves the hydrometer. The determination of the densities of bodies, as given by Alhazen, approach very closely to our own. "I join," says Draper, "in the pious prayer of Alhazen, that in the day of judgment the All-Merciful will take pity on the soul of Abur-Raihân, because he was the first of the race of men to construct a table of specific gravities." If all this be historic truth (and I have entire confidence in Dr. Draper), well may he "deplore the systematic manner in which the literature of Europe has contrived to put out of sight our scientific obligations to the Mahommedans."*

Towards the close of the stationary period a word-weariness, if I may so express it, took more and more possession of men's minds. Christendom had become sick of the School philosophy and its verbal wastes, which led to no issue, but left the intellect in everlasting haze. Here and there was heard the voice of one impatiently crying in the wilderness, "Not unto Aristotle, not unto subtle hypotheses, not unto Church, Bible, or blind tradition, must we turn for a knowledge of the universe, but to the direct investigation of nature by observation and experiment." In 1543 the epoch-making work of Copernicus on the paths of the heavenly bodies appeared. The total crash of Aristotle's closed universe with the earth at its centre followed as a consequence; and "the earth moves" became a kind of watchword among intellectual freemen. Copernicus was canon of the church of Frauenburg, in the diocese of Ermeland. For three-and-thirty years he had withdrawn himself from the world, and devoted himself to the consolidation of his great scheme of the solar system. He made its blocks eternal; and even to those who feared it and desired its overthrow it was so obviously strong that they refrained for a time from meddling with it. In the last year of the life of Copernicus his book appeared: it is said that the old man received a copy of it a few days before his death, and then departed in peace.

The Italian philosopher, Giordano Bruno, was one of the earliest converts to the new astronomy. Taking Lucretius as his exemplar, he revived the notion of the infinity of worlds; and combining with it the doctrine of Copernicus, reached the sublime generalization that the fixed stars are suns, scattered numberless through space and accompanied by satellites, which bear the same relation to them that our earth does to our sun, or our moon to our earth. This was an expansion of transcendent import; but Bruno came closer than this to our present line of thought. Struck with the problem of the generation and maintenance of organisms, and duly pondering it, he came to the conclusion that Nature in her productions does not imitate the technic of man. Her process is one of unravelling and unfolding. The infinity of forms under which matter appears were not imposed upon it by an external artificer; by its own intrinsic force and virtue it brings these forms forth. Matter is not the mere naked, empty *capacity* which philosophers have pictured her to be, but the universal mother, who brings forth all things as the fruit of her own womb.

This outspoken man was originally a Dominican monk. He was accused of heresy and had to fly, seeking refuge in Geneva, Paris, England, and Germany. In 1592 he fell into the hands of the Inquisition at Venice. He was imprisoned for many years, tried, degraded, excommunicated, and handed over to the civil power, with the request that he should be treated gently and "without the shedding of blood." This meant that he was to be burnt, and burnt accordingly he was, on the 16th Feb-

* 'Intellectual Development of Europe,' p. 359.

ruary, 1600. To escape a similar fate Galileo, thirty-three years afterwards, abjured, upon his knees, and with his hand upon the holy gospels, the heliocentric doctrine. After Galileo came Kepler, who from his German home defied the power beyond the Alps. He traced out from pre-existing observations the laws of planetary motion. The problem was thus prepared for Newton, who bound those empirical laws together by the principle of gravitation.

During the Middle Ages the doctrine of atoms had to all appearance vanished from discussion. In all probability it held its ground among sober-minded and thoughtful men, though neither the church nor the world was prepared to hear of it with tolerance. Once, in the year 1348, it received distinct expression. But retractation by compulsion immediately followed, and thus discouraged it slumbered till the 17th century, when it was revived by a contemporary of Hobbes and Descartes, the Père Gassendi.

The analytic and synthetic tendencies of the human mind exhibit themselves throughout history, great writers ranging themselves sometimes on the one side, sometimes on the other. Men of lofty feelings, and minds open to the elevating impressions produced by nature as a whole, whose satisfaction, therefore, is rather ethical than logical, have leaned to the synthetic side; while the analytic harmonizes best with the more precise and more mechanical bias which seeks the satisfaction of the understanding. Some form of pantheism was usually adopted by the one, while a detached Creator, working more or less after the manner of men, was often assumed by the other.* Gassendi is hardly to be ranked with either. Having formally acknowledged God as the great first cause, he immediately drops the idea, applies the known laws of mechanics to the atoms, and thence deduces all vital phenomena. God who created earth and water, plants and animals, produced in the first place a definite number of atoms, which constituted the seed of all things. Then began that series of combinations and decompositions which goes on at the present day, and which will continue in the future. The principle of every change resides in matter. In artificial productions the moving principle is different from the material worked upon; but in nature the agent works within, being the most active and mobile part of the material itself. Thus this bold ecclesiastic, without incurring the censure of the church or the world, contrives to outstrip Mr. Darwin. The same cast of mind which caused him to detach the Creator from his universe led him also to detach the soul from the body, though to the body he ascribes an influence so large as to render the soul almost unnecessary. The aberrations of reason were in his view an affair of the material brain. Mental disease is brain-disease; but then the immortal reason sits apart, and cannot be touched by the disease. The errors of madness are errors of the instrument, not of the performer.

It may be more than a mere result of education, connecting itself probably with the deeper mental structure of the two men, that the idea of Gassendi, above enunciated, is substantially the same as that expressed by Professor Clerk Maxwell at the close of the very noble lecture delivered by him at Bradford last year. According to both philosophers, the atoms, if I understand aright, are the *prepared materials*, the "manufactured articles," which, formed by the skill of the Highest, produce by their subsequent interaction all the phenomena of the material world. There seems to be this difference, however, between Gassendi and Maxwell. The one *postulates*, the other *infers* his first cause. In his manufactured articles, Professor Maxwell finds the basis of an induction, which enables him to scale philosophic heights considered inaccessible by Kant, and to take the logical step from the atoms to their Maker.

The atomic doctrine, in whole or in part, was entertained by Bacon, Descartes, Hobbes, Locke, Newton, Boyle, and their successors, until the chemical law of multiple proportions enabled Dalton to confer upon it an entirely new significance. In our day there are secessions from the theory, but it still stands firm. Only a year or two ago Sir William Thomson, with characteristic penetration, sought to determine the sizes of the atoms, or rather to fix the limits between which their sizes lie; while only last year the discourses of Williamson and Maxwell illustrate the present hold of the doctrine upon the foremost scientific minds. What these atoms, self-moved and self-posited, can and cannot accomplish in relation to life, is at the present moment the subject of profound scientific thought. I doubt the legitimacy of Maxwell's logic; but it is impossble not to feel the ethic glow with which his lecture concludes. There is, moreover, a Lucretian grandeur in his description of the steadfastness of the atoms:—"Natural causes, as we know, are at work, which tend to modify, if they do not at length destroy, all the arrangements and dimensions of the earth and the whole solar system. But though in the course of ages catastrophes have occurred and may yet occur in the heavens, though ancient systems may be dissolved and new systems evolved out of their ruins, the molecules out of which these systems are built, the foundation stones of the material universe, remain unbroken and unworn."

Ninety years subsequent to Gassendi the doctrine of bodily instruments, as it may be called, assumed immense importance in the hands of Bishop Butler, who, in his famous 'Analogy of Religion,' developed, from his own point of view, and with consummate sagacity, a similar idea. The Bishop still influences superior minds; and it will repay us to dwell for a moment on his views. He draws the sharpest distinction between our real selves and our bodily instruments. He does not, as far as I remember, use the word soul, possibly because the term was so hackneyed in his day as it had been for many generations previously. But he speaks of "living powers," "perceiving" or "percipient powers," "moving agents," "ourselves," in the same sense as we should employ the term soul. He dwells upon the fact that limbs may be removed, and mortal diseases assail the body, while the mind, almost up to the moment of death, remains clear. He refers to sleep and to swoon, where the "living powers" are suspended, but not destroyed. He considers it quite as easy to conceive of an existence out of our bodies as in them; that we may animate a succession of bodies, the dissolution of all of them having no more tendency to dissolve our real selves, or "deprive us of living faculties—the faculties of perception and action—than the dissolution of any foreign matter which we are capable of receiving impressions from, or making use of for the common occasions of life." This is the key of the Bishop's position: "our organized bodies are no more a part of ourselves than any other matter around us." In proof of this he calls attention to the use of glasses, which "prepare objects" for the "percipient power" exactly as the eye does. The eye itself is no more percipient than the glass, and is quite as much the instrument of the true self, and also as foreign to the true self, as the glass is. "And if we see with our eyes only in the same manner as we do with glasses, the like may justly be concluded from analogy of all our senses."

Lucretius, as you are aware, reached a precisely opposite conclusion; and it certainly would be interesting, if not profitable, to us all, to hear what he would or could urge in opposition to the reasoning of the Bishop. As a brief discussion of the point will enable us to see the bearings of an important question, I will here permit a disciple of Lucretius to try the strength of the Bishop's position, and

---

* Boyle's model of the universe was the Strasburg clock with an outside Artificer. Goethe, on the other hand, sang

"Ihm ziemt's die Welt im Innern zu bewegen,
Natur in sich, sich in Natur zu hegen."

The same repugnance to the Clockmaker conception is manifest in Carlyle.

then allow the Bishop to retaliate, with the view of rolling back, if he can, the difficulty upon Lucretius. Each shall state his case fully and frankly; and you shall be umpire between them.

The argument might proceed in this fashion:—

"Subjected to the test of mental presentation (*Vorstellung*), your views, most honoured prelate, would present to many minds a great, if not an insuperable difficulty. You speak of 'living powers,' 'percipient or perceiving powers,' and 'ourselves;' but can you form a mental picture of any one of these apart from the organism through which it is supposed to act? Test yourself honestly, and see whether you possess any faculty that would enable you to form such a conception. The true self has a local habitation in each of us; thus localized, must it not possess a form? If so, what form? Have you ever for a moment realized it? When a leg is amputated the body is divided into two parts; is the true self in both of them or in one? Thomas Aquinas might say in both; but not you, for you appeal to the consciousness associated with one of the two parts to prove that the other is foreign matter. Is consciousness, then, a necessary element of the true self? If so, what do you say to the case of the whole body being deprived of consciousness? If not, then on what grounds do you deny any portion of the true self to the severed limb? It seems very singular that, from the beginning to the end of your admirable book (and no one admires its sober strength more than I do), you never once mention the brain or nervous system. You begin at one end of the body, and show that its parts may be removed without prejudice to the perceiving power. What if you begin at the other end, and remove, instead of the leg, the brain? The body, as before, is divided into two parts; but both are now in the same predicament, and neither can be appealed to to prove that the other is foreign matter. Or, instead of going so far as to remove the brain itself, let a certain portion of its bony covering be removed, and let a rhythmic series of pressures and relaxations of pressure be applied to the soft substance. At every pressure 'the faculties of perception and of action,' vanish; at every relaxation of pressure they are restored. Where, during the intervals of pressure, is the perceiving power? I once had the discharge of a large Leyden battery passed unexpectedly through me: I felt nothing, but was simply blotted out of conscious existence for a sensible interval. Where was my true self during that interval? Men who have recovered from lightning-stroke have been much longer in the same state; and indeed in cases of ordinary concussion of the brain, days may elapse during which no experience is registered in consciousness. Where is the man himself during the period of insensibility? You may say that I beg the question when I assume the man to have been unconscious, that he was really conscious all the time, and has simply forgotten what had occurred to him. In reply to this I can only say that no one need shrink from the worst tortures that superstition ever invented if only so felt and so remembered. I do not think your theory of instruments goes at all to the bottom of the matter. A telegraph-operator has his instruments, by means of which he converses with the world; our bodies possess a nervous system, which plays a similar part between the perceiving power and external things. Cut the wires of the operator, break his battery, demagnetize his needle: by this means you certainly sever his connection with the world; but inasmuch as these are real instruments, their destruction does not touch the man who uses them. The operator survives, *and he knows that he survives.* What is it, I would ask, in the human system that answers to this conscious survival of the operator when the battery of the brain is so disturbed as to produce insensibility, or when it is destroyed altogether?

"Another consideration, which you may consider slight, presses upon me with some force. The brain may change from health to disease, and through such a change the most exemplary man may be converted into a debauchee or a murderer. My very noble and approved good master had, as you know, threatenings of lewdness introduced into his brain by his jealous wife's philter; and sooner than permit himself to run even the risk of yielding to these base promptings he slew himself. How could the hand of Lucretius have been thus turned against himself if the real Lucretius remained as before? Can the brain or can it not act in this distempered way without the intervention of the immortal reason? If it can, then it is a prime mover which requires only healthy regulation to render it reasonably self-acting, and there is no apparent need of your immortal reason at all. If it cannot, then the immortal reason, by its mischievous activity in operating upon a broken instrument, must have the credit of committing every imaginable extravagance and crime. I think, if you will allow me to say so, that the gravest consequences are likely to flow from your estimate of the body. To regard the brain as you would a staff or an eyeglass—to shut your eyes to all its mystery, to the perfect correlation that reigns between its condition and our consciousness, to the fact that a slight excess or defect of blood in it produces that very swoon to which you refer, and that in relation to it our meat and drink and air and exercise have a perfectly transcendental value and significance—to forget all this does, I think, open a way to innumerable errors in our habits of life, and may possibly in some cases initiate and foster that very disease, and consequent mental ruin, which a wiser appreciation of this mysterious organ would have avoided."

I can imagine the Bishop thoughtful after hearing this argument. He was not the man to allow anger to mingle with the consideration of a point of this kind. After due consideration, and having strengthened himself by that honest contemplation of the facts which was habitual with him, and which includes the desire to give even adverse facts their due weight, I can suppose the Bishop to proceed thus:—"You will remember that in the 'Analogy of Religion,' of which you have so kindly spoken, I did not profess to prove anything absolutely, and that I over and over again acknowledged and insisted on the smallness of our knowledge, or rather the depth of our ignorance, as regards the whole system of the universe. My object was to show my deistical friends, who set forth so eloquently the beauty and beneficence of Nature and the Ruler thereof, while they had nothing but scorn for the so-called absurdities of the Christian scheme, that they were in no better condition than we were, and that, for every difficulty they found upon our side, quite as great a difficulty was to be found upon theirs. I will now, with your permission, adopt a similar line of argument. You are a Lucretian, and from the combination and separation of atoms deduce all terrestrial things, including organic forms and their phenomena. Let me tell you in the first instance how far I am prepared to go with you. I admit that you can build crystalline forms out of this play of molecular force; that the diamond, amethyst, and snow-star are truly wonderful structures which are thus produced. I will go further and acknowledge that even a tree or flower might in this way be organized. Nay, if you can show me an animal without sensation, I will concede to you that it also might be put together by the suitable play of molecular force.

"Thus far our way is clear, but now comes my difficulty. Your atoms are individually without sensation, much more are they without intelligence. May I ask you, then, to try your hand upon this problem. Take your dead hydrogen atoms, your dead oxygen atoms, your dead carbon atoms, your dead nitrogen atoms, your dead phosphorous atoms, and all the other atoms, dead as grains of shot, of which the brain is formed. Imagine them separate and sensationless; observe them running together and forming all imaginable combinations. This, as a purely mechanical process, is *seeable* by the mind. But can you see, or dream, or in any way imagine, how out of that mechanical act, and from these individually dead atoms, sensation, thought, and emotion are to arise? You speak of the difficulty of mental presentation in my case; is it less in yours? I am not all bereft of this *Vorstellungs-Kraft* of which you speak. I can follow a particle of musk until it reaches the olfactory nerve: I can follow the waves of sound until their tremors reach the water of the labyrinth, and set the otoliths and Corti's fibres in motion; I can also visualize the waves of ether as they cross the eye and hit the retina. Nay, more, I am able to follow up to the central organ the motion thus imparted at the periphery, and to see in idea the very molecules of the brain thrown into tremors. My insight is not baffled by these physical processes. What baffles me, what I find unimaginable, transcending every faculty I possess—transcending, I humbly submit, every faculty *you* possess—is the notion that out of those physical tremors you can extract things so utterly incongruous with them as sensation, thought, and emotion. You may say, or think, that this issue of consciousness from the clash of atoms is not more incongruous than the flash of light from the union of oxygen and hydrogen. But I beg to say that it is. For such incongruity as the flash possesses is that which I now force upon your attention. The flash is an affair of consciousness, the objective counterpart of which is a vibration. It is a flash only by your interpretation. *You* are the cause of the apparent incongruity; and *you* are the thing that puzzles me. I need not remind you that the great Leibnitz felt the difficulty which I feel, and that to get rid of this monstrous deduction of life from death he displaced your atoms by his monads, which were more or less perfect mirrors of the universe, and out of the summation and integration of which he supposed all the phenomena of life—sentient, intellectual, and emotional—to arise.

"Your difficulty, then, as I see you are ready to admit, is quite as great as mine. You cannot satisfy the human understanding in its demand for logical continuity between molecular processes and the phenomena of consciousness. This is a rock on which materialism must inevitably split whenever it pretends to be a complete philosophy of life. What is the moral, my Lucretian? You and I are not likely to indulge in ill-temper in the discussion of these great topics, where we see so much room for honest differences of opinion. But there are people of less wit, or more bigotry (I say it with humility) on both sides, who are ever ready to mingle anger and vituperation with such discussions. There are, for example, writers of note and influence at the present day who are not ashamed to assume the 'deep personal sin' of a great logician to be the cause of his unbelief in a theologic dogma. And there are others who hold that we, who cherish our noble Bible, wrought as it has been into the constitution of our forefathers, and by inheritance into us, must necessarily be hypocritical and insincere. Let us disavow and discountenance such people, cherishing the unswerving faith that what is good and true in both our arguments will be preserved for the benefit of humanity, while all that is bad or false will disappear."

It is worth remarking that in one respect the Bishop was a product of his age. Long previous to his day the nature of the soul had been so favourite and general a topic of discussion, that, when the students of the University of Paris wished to know the leanings of a new Professor, they at once requested him to lecture upon the soul. About the time of Bishop Butler the question was not only agitated but extended. It was seen by the clear-witted men who entered this arena that many of their best arguments applied equally to brutes and men. The Bishop's arguments were of this character. He saw it, admitted it, accepted the consequences, and boldly embraced the whole animal world in his scheme of immortality.

Bishop Butler accepted with unwavering trust the chronology of the Old Testament, describing it as "confirmed by the natural and civil history of the world, collected from common historians, from the state of the earth, and from the late inventions of arts and sciences." These words mark progress: they must seem somewhat hoary to the Bishop's successors of to-day.* It is hardly necessary to inform you that since his time the domain of the naturalist has been immensely extended—the whole science of geology, with its astounding revelations regarding the life of the ancient earth, having been created. The rigidity of old conceptions has been relaxed, the public mind being rendered gradually tolerant of the idea that not for six thousand, nor for sixty thousand, nor for six thousand thousand, but for æons embracing untold millions of years, this earth has been the theatre of life and death. The riddle of the rocks has been read by the geologist and palæontologist, from subcambrian depths to the deposits thickening over the sea-bottoms of to-day. And upon the leaves of that stone book are, as you know, stamped the characters, plainer and surer than those formed by the ink of history, which carry the mind back into abysses of past time compared with which the periods which satisfied Bishop Butler cease to have a visual angle. Everybody now knows this; all men admit it; still, when they were first broached these verities of science found loud-tongued denunciators, who proclaimed not only their baselessness considered scientifically, but their immorality considered as questions of ethics and religion: the Book of Genesis had stated the question in a different fashion; and science must necessarily go to pieces when it clashed with this authority. And as the seed of the thistle produces a thistle, and nothing else, so these objectors scatter their germs abroad, and reproduce their kind, ready to play again the part of their intellectual progenitors, to show the same virulence, the same ignorance, to achieve for a time the same success, and finally to suffer the same inexorable defeat. Surely the time must come at last when human nature in its entirety, whose legitimate demands it is admitted science alone cannot satisfy, will find interpreters and expositors of a different stamp from those rash and ill-informed persons who have been hitherto so ready to hurl themselves against every new scientific revelation, lest it should endanger what they are pleased to consider theirs.

The lode of discovery once struck, those petrified forms in which life was at one time active, increased to multitudes and demanded classification. The general fact soon became evident that none but the simplest forms of life lie lowest down, that as we climb higher and higher among the superimposed strata more perfect forms appear. The change, however, from form to form was not continuous—but by steps, some small, some great. "A section," says Mr. Huxley, "a hundred feet thick will exhibit, at different heights, a dozen species of Ammonite, none of which passes beyond its particular zone of limestone, or clay into the zone below it, or into that above it." In the presence of such facts it was not possible to avoid the question:—Have these forms, showing, though in broken stages and with many irregularities, this unmistakable general advance, been subjected to no continuous law of growth or variation? Had our education been purely scientific, or had it been sufficiently detached from influences which, however ennobling in another domain, have always proved hindrances and delusions when introduced as factors into the domain of physics, the scientific mind never could have swerved from the search for a law of growth, or allowed itself to accept the anthropomorphism which regarded each successive stratum as a kind of mechanic's bench for the manufacture of new species out of all relation to the old.

Biassed, however, by their previous education, the great majority of naturalists invoked a special creative act to account for the appearance of each new group of organisms. Doubtless there were numbers who were clear-headed enough to see that this was no explanation at all, that in

* Only to some; for there are dignitaries who even now speak of the earth's rocky crust as so much building material prepared for man at the Creation. Surely it is time that this loose language should cease.

point of fact it was an attempt, by the introduction of a greater difficulty, to account for a less. But having nothing to offer in the way of explanation, they for the most part held their peace. Still the thoughts of reflecting men naturally and necessarily simmered round the question. De Maillet, a contemporary of Newton, has been brought into notice by Professor Huxley as one who "had a notion of the modifiability of living forms." In my frequent conversations with him, the late Sir Benjamin Brodie, a man of highly philosophic mind, often drew my attention to the fact that, as early as 1794, Charles Darwin's grandfather was the pioneer of Charles Darwin. In 1801, and in subsequent years, the celebrated Lamarck, who produced so profound an impression on the public mind through the vigorous exposition of his views by the author of the 'Vestiges of Creation,' endeavoured to show the development of species out of changes of habit and external condition. In 1813 Dr. Wells, the founder of our present theory of Dew, read before the Royal Society a paper in which, to use the words of Mr. Darwin, "he distinctly recognizes the principle of natural selection; and this is the first recognition that has been indicated." The thoroughness and skill with which Wells pursued his work, and the obvious independence of his character, rendered him long ago a favourite with me; and it gave me the liveliest pleasure to alight upon this additional testimony to his penetration. Professor Grant, Mr. Patrick Matthew, Von Buch, the author of the 'Vestiges,' D'Halloy, and others,* by the enunciation of views more or less clear and correct, showed that the question had been fermenting long prior to the year 1858, when Mr. Darwin and Mr. Wallace simultaneously but independently placed their closely concurrent views upon the subject before the Linnean Society.

These papers were followed in 1859 by the publication of the first edition of 'The Origin of Species.' All great things come slowly to the birth. Copernicus, as I informed you, pondered his great work for thirty-three years. Newton for nearly twenty years kept the idea of Gravitation before his mind; for twenty years also he dwelt upon his discovery of Fluxions, and doubtless would have continued to make it the object of his private thought had he not found that Leibnitz was upon his track. Darwin for two-and-twenty-years pondered the problem of the origin of species, and doubtless he would have continued to do so had he not found Wallace upon his track.† A concentrated, but full and powerful epitome of his labours was the consequence. The book was by no means an easy one; and probably not one in every score of those who then attacked it had read its pages through, or were competent to grasp their significance if they had. I do not say this merely to discredit them; for there were in those days some really eminent scientific men entirely raised above the heat of popular prejudice, willing to accept any conclusion that science had to offer, provided it was duly backed by fact and argument, and who entirely mistook Mr. Darwin's views. In fact the work needed an expounder; and it found one in Mr. Huxley. I know nothing more admirable in the way of scientific exposition than those early articles of his on the origin of species. He swept the curve of discussion through the really significant points of the subject, enriched his exposition with profound original remarks and reflections, often summing up in a single pithy sentence an argument which a less compact mind would have spread over pages. But there is one impression made by the book itself which no exposition of it, however luminous, can convey; and that is the impression of the vast amount of labour, both of observation and of thought, implied in its production. Let us glance at its principles.

It is conceded on all hands that what are called varieties are continually produced. The rule is probably without exception. No chick and no child is in all respects and particulars the counterpart of its brother or sister; and in such differences we have "variety" incipient. No naturalist could tell how far this variation could be carried; but the great mass of them held that never by any amount of internal or external change, nor by the mixture of both, could the offspring of the same progenitor so far deviate from each other as to constitute different species. The function of the experimental philosopher is to combine the conditions of nature and to produce her results; and this was the method of Darwin.* He made himself acquainted with what could, without any manner of doubt, be done in the way of producing variation. He associated himself with pigeon-fanciers—bought, begged, kept, and observed every breed that he could obtain. Though derived from a common stock, the diversities of these pigeons were such that "a score of them might be chosen which, if shown to an ornithologist, and he were told that they were wild birds, would certainly be ranked by him as well-defined species." The simple principle which guides the pigeon-fancier, as it does the cattle-breeder, is the selection of some variety that strikes his fancy, and the propagation of this variety by inheritance. With his eye still upon the particular appearance which he wishes to exaggerate, he selects it as it reappears in successive broods, and thus adds increment to increment until an astonishing amount of divergence from the parent type is effected. Man in this case does not produce the *elements* of the variation. He simply observes them, and by selection adds them together until the required result has been obtained. "No man," says Mr. Darwin, "would ever try to make a fantail till he saw a pigeon with a tail developed in some slight degree in an unusual manner, or a pouter until he saw a pigeon with a crop of unusual size." Thus Nature gives the hint, man acts upon it, and by the law of inheritance exaggerates the deviation.

Having thus satisfied himself by indubitable facts that the organization of an animal or of a plant (for precisely the same treatment applies to plants) is to some extent plastic, he passes from variation under domestication to variation under nature. Hitherto we have dealt with the adding together of small changes by the conscious selection of man. Can Nature thus select? Mr. Darwin's answer is, "Assuredly she can." The number of living things produced is far in excess of the number that can be supported; hence at some period or other of their lives there must be a struggle for existence; and what is the infallible result? If one organism were a perfect copy of the other in regard to strength, skill, and agility, external conditions would decide. But this is not the case. Here we have the fact of variety offering itself to nature, as in the former instance it offered itself to man; and those varieties which are least competent to cope with surrounding conditions will infallibly give way to those that are most competent. To use a familiar proverb, the weakest comes to the wall. But the triumphant fraction again breeds to over-production, transmitting the qualities which secured its maintenance, but transmitting them in different degrees. The struggle for food again supervenes, and those to whom the favourable quality has been transmitted in excess will assuredly triumph. It is easy to see that we have here the addition of increments favourable to the individual still more rigorously carried out than in the case of domestication; for not only are unfavourable specimens not selected by nature, but they are destroyed. This is what Mr. Darwin calls "natural selection," which "acts by the preserva-

* In 1855 Mr. Herbert Spencer ('Principles of Psychology,' 2nd edit. vol. i., p. 465) expressed "the belief that life under all its forms has arisen by an unbroken evolution, and through the instrumentality of what are called natural causes."

† The behaviour of Mr. Wallace in relation to this subject has been dignified in the highest degree.

* The first step only towards experimental demonstration has been taken. Experiments now begun might, a couple of centuries hence, furnish data of incalculable value, which ought to be supplied to the science of the future.

tion and accumulation of small inherited modifications, each profitable to the preserved being." With this idea he interpenetrates and leavens the vast store of facts that he and others have collected. We cannot, without shutting our eyes through fear or prejudice, fail to see that Darwin is here dealing, not with imaginary, but with true causes; nor can we fail to discern what vast modifications may be produced by natural selection in periods sufficiently long. Each individual increment may resemble what mathematicians call a "differential" (a quantity indefinitely small); but definite and great changes may obviously be produced by the integration of these infinitesimal quantities through practically infinite time.

If Darwin, like Bruno, rejects the notion of creative power acting after human fashion, it certainly is not because he is unacquainted with the numberless exquisite adaptations on which this notion of a supernatural artificer has been founded. His book is a repository of the most startling facts of this description. Take the marvellous observation which he cites from Dr. Crüger, where a bucket, with an aperture serving as a spout, is formed in an orchid. Bees visit the flower; in eager search of material for their combs they push each other into the bucket, the drenched ones escaping from their involuntary bath by the spout. Here they rub their backs against the viscid stigma of the flower and obtain glue; then against the pollen masses, which are thus stuck to the back of the bee and carried away. "When the bee, thus provided, flies to another flower, or to the same flower a second time, and is pushed by its comrades into the bucket, and then crawls out by the passage, the pollen-mass upon its back necessarily comes first into contact with the viscid stigma," which takes up the pollen; and this is how that orchid is fertilized. Or take this other case of the *Catasetum*. "Bees visit these flowers in order to gnaw the labellum; on doing this they inevitably touch a long, tapering, sensitive projection. This, when touched, transmits a sensation or vibration to a certain membrane, which is instantly ruptured, setting free a spring, by which the pollen-mass is shot forth like an arrow in the right direction, and adheres by its viscid extremity to the back of the bee." In this way the fertilizing pollen is spread abroad.

It is the mind thus stored with the choicest materials of the teleologists that rejects teleology, seeking to refer these wonders to natural causes. They illustrate, according to him, the method of nature, not the "technic" of a man-like Artificer. The beauty of flowers is due to natural selection. Those that distinguish themselves by vividly contrasting colours from the surrounding green leaves are most readily seen, most frequently visited by insects, most often fertilized, and hence most favoured by natural selection. Coloured berries also readily attract the attention of birds and beasts, which feed upon them, spread their manured seeds abroad, thus giving trees and shrubs possessing such berries a greater chance in the struggle for existence.

With profound analytic and synthetic skill, Mr. Darwin investigates the cell-making instinct of the hive-bee. His method of dealing with it is representative. He falls back from the more perfectly to the less perfectly developed instinct—from the hive-bee to the humble bee, which uses its own cocoon as a comb, and to classes of bees of intermediate skill, endeavouring to show how the passage might be gradually made from the lowest to the highest. The saving of wax is the most important point in the economy of bees. Twelve to fifteen pounds of dry sugar are said to be needed for the secretion of a single pound of wax. The quantities of nectar necessary for the wax must therefore be vast; and every improvement of constructive instinct which results in the saving of wax is a direct profit to the insect's life. The time that would otherwise be devoted to the making of wax is now devoted to the gathering and storing of honey for winter food. He passes from the humble bee with its rude cells, through the Melipona with its more artistic cells, to the hive-bee with its astonishing architecture. The bees place themselves at equal distances apart upon the wax, sweep and excavate equal spheres round the selected points. The spheres intersect, and the planes of intersection are built up with thin laminæ. Hexagonal cells are thus formed. This mode of treating such questions is, as I have said, representative. He habitually retires from the more perfect and complex, to the less perfect and simple, and carries you with him through stages of *perfecting*, adds increment to increment of infinitesimal change, and in this way gradually breaks down your reluctance to admit that the exquisite climax of the whole could be a result of natural selection.

Mr. Darwin shirks no difficulty; and, saturated as the subject was with his own thought, he must have known, better than his critics, the weakness as well as the strength of his theory. This of course would be of little avail were his object a temporary dialectic victory instead of the establishment of a truth which he means to be everlasting. But he takes no pains to disguise the weakness he has discerned; nay, he takes every pains to bring it into the strongest light. His vast resources enable him to cope with objections started by himself and others, so as to leave the final impression upon the reader's mind that, if they be not completely answered, they certainly are not fatal. Their negative force being thus destroyed, you are free to be influenced by the vast positive mass of evidence he is able to bring before you. This largeness of knowledge and readiness of resource render Mr. Darwin the most terrible of antagonists. Accomplished naturalists have levelled heavy and sustained criticisms against him—not always with the view of fairly weighing his theory, but with the express intention of exposing its weak points only. This does not irritate him. He treats every objection with a soberness and thoroughness which even Bishop Butler might be proud to imitate, surrounding each fact with its appropriate detail, placing it in its proper relations, and usually giving it a significance which, as long as it was kept isolated, failed to appear. This is done without a trace of ill-temper. He moves over the subject with the passionless strength of a glacier; and the grinding of the rocks is not always without a counterpart in the logical pulverization of the objector. But though in handling this mighty theme all passion has been stilled, there is an emotion of the intellect incident to the discernment of new truth which often colours and warms the pages of Mr. Darwin. His success has been great; and this implies not only the solidity of his work, but the preparedness of the public mind for such a revelation. On this head a remark of Agassiz impressed me more than anything else. Sprung from a race of theologians, this celebrated man combated to the last the theory of natural selection. One of the many times I had the pleasure of meeting him in the United States was at Mr. Winthrop's beautiful residence at Brookline, near Boston. Rising from luncheon, we all halted as if by a common impulse in front of a window, and continued there a discussion which had been started at table. The maple was in its autumn glory; and the exquisite beauty of the scene outside seemed, in my case, to interpenetrate without disturbance the intellectual action. Earnestly, almost sadly, Agassiz turned, and said to the gentlemen standing round, "I confess that I was not prepared to see this theory received as it has been by the best intellects of our time. Its success is greater than I could have thought possible."

In our day great generalizations have been reached. The theory of the origin of species is but one of them. Another, of still wider grasp and more radical significance, is the doctrine of the Conservation of Energy, the ultimate philosophical issues of which are as yet but dimly seen—that doctrine which "binds nature fast in fate" to an extent not hitherto recognized, exacting from every antecedent its equivalent consequent, from every consequent its equivalent antecedent, and bringing vital as well as physical phenomena under the dominion of that law of causal connection which, as far as the human understanding has yet pierced, asserts itself everywhere in nature. Long in advance of all definite experiment upon the subject, the constancy and indestructibility of matter had been affirmed; and all subsequent experience justified the affirmation. Later researches extended the attribute of indestructibility to force. This idea, applied in the first instance to inorganic, rapidly embraced organic nature. The vegetable world, though drawing almost all its nutriment from invisible sources, was proved incompetent to generate anew either matter or force. Its matter is for the most part transmuted air; its force transformed solar force. The animal world was proved to be equally uncreative, all its motive energies being referred to the combustion of its food. The activity of each animal as a whole was proved to be the transferred activities of its molecules. The muscles were shown to be stores of mechanical force, potential until unlocked by the nerves, and then resulting in muscular contractions. The speed at which messages fly to and fro along the nerves was determined, and found to be, not as had been previously supposed, equal to that of light or electricity, but less than the speed of a flying eagle.

This was the work of the physicist: then came the conquests of the comparative anatomist and physiologist, revealing the structure of every animal, and the function of every organ in the whole biological series, from the lowest zoophyte up to man. The nervous system had been the object of profound and continued study, the wonderful and, at bottom, entirely mysterious, controlling power which it exercises over the whole organism, physical and mental, being recognized more and more. Thought could not be kept back from a subject so profoundly suggestive. Besides the physical life dealt with by Mr. Darwin, there is a psychical life presenting similar gradations, and asking equally for a solution. How are the different grades and orders of Mind to be accounted for? What is the principle of growth of that mysterious power which on our planet culminates in Reason? These are questions which, though not thrusting themselves so forcibly upon the attention of the general public, had not only occupied many reflecting minds, but had been formally broached by one of them before the 'Origin of Species' appeared.

With the mass of materials furnished by the physicist and physiologist in his hands, Mr. Herbert Spencer, twenty years ago, sought to graft upon this basis a system of psychology: and two years ago a second and greatly amplified edition of his work appeared. Those who have occupied themselves with the beautiful experiments of Plateau will remember that when two spherules of olive oil suspended in a mixture of alcohol and water of the same density as the oil, are brought together, they do not immediately unite. Something like a pellicle appears to be formed around the drops, the rupture of which is immediately followed by the coalescence of the globules into one. There are organisms whose vital actions are almost as purely physical as that of these drops of oil. They come into contact and fuse themselves thus together. From such organisms to others a shade higher, and from these to others a shade higher still, and on through an ever-ascending series, Mr. Spencer conducts his argument. There are two obvious factors to be here taken into account—the creature and the medium in which it lives, or, as it is often expressed, the organism and its environment. Mr. Spencer's fundamental principle is, that between these two factors there is incessant interaction. The organism is played upon by the environment, and is modified to meet the requirements of the environment. Life he defines to be "a continuous adjustment of internal relations to external relations."

In the lowest organisms we have a kind of tactual sense diffused over the entire body; then, through impressions from without and their corresponding adjustments, special portions of the surface become more responsive to stimuli than others. The senses are nascent, the basis of all of them being that simple tactual sense which the sage Democritus recognized 2300 years ago as their common progenitor. The action of light, in the first instance, appears to be a mere disturbance of the chemical processes in the animal organism, similar to that which occurs in the leaves of plants. By degrees the action becomes localized in a few pigment cells, more sensitive to light than the surrounding tissue. The eye is here incipient. At first it is merely capable of revealing differences of light and shade produced by bodies close at hand. Followed as the interception of the light is in almost all cases by the contact of the closely adjacent opaque body, sight in this condition becomes a kind of "anticipatory touch." The adjustment continues; a slight bulging out of the epidermis over the pigment-granules supervenes. A lens is incipient, and, through the operation of infinite adjustments, at length reaches the perfection that it displays in the hawk and eagle. So of the other senses; they are special differentiations of a tissue which was originally vaguely sensitive all over.

With the development of the senses the adjustments between the organism and its environment gradually extend in *space*, a multiplication of experiences and a corresponding modification of conduct being the result. The adjustments also extend in *time*, covering continually greater intervals. Along with this extension in space and time the adjustments also increase in speciality and complexity, passing through the various grades of brute life, and prolonging themselves into the domain of reason. Very striking are Mr. Spencer's remarks regarding the influence of the sense of touch upon the development of intelligence. This is, so to say, the mother-tongue of all the senses, into which they must be translated to be of service to the organism. Hence its importance. The parrot is the most intelligent of birds, and its tactual power is also greatest. From this sense it gets knowledge unattainable by birds which cannot employ their feet as hands. The elephant is the most sagacious of quadrupeds—its tactual range and skill, and the consequent multiplication of experiences, which it owes to its wonderfully adaptable trunk, being the basis of its sagacity. Feline animals, for a similar cause, are more sagacious than hoofed animals,—atonement being to some extent made, in the case of the horse, by the possession of sensitive prehensile lips. In the *Primates* the evolution of intellect and the evolution of tactual appendages go hand in hand. In the most intelligent anthropoid apes we find the tactual range and delicacy greatly augmented, new avenues of knowledge being thus opened to the animal. Man crowns the edifice here, not only in virtue of his own manipulatory power, but through the enormous extension of his range of experience, by the invention of instruments of precision, which serve as supplemental senses and supplemental limbs. The reciprocal action of these is finely described and illustrated. That chastened intellectual emotion to which I have referred in connexion with Mr. Darwin is, I should say, not absent in Mr. Spencer. His illustrations possess at times exceeding vividness and force; and from his style on such occasions it is to be inferred that the ganglia of this Apostle of the Understanding are sometimes the seat of a nascent poetic thrill.

It is a fact of supreme importance that actions the performance of which at first requires even painful effort and deliberation, may by habit be rendered automatic. Witness the slow learning of its letters by a child, and the subsequent facility of reading in a man, when each group of letters which forms a word is instantly, and without effort, fused to a single perception. Instance the billiard-player, whose muscles of hand and eye, when he reaches the perfection of his art, are unconsciously co-ordinated. Instance the musician, who, by practice, is enabled to fuse a multitude of arrangements, auditory, tactual and muscular, into a process of automatic manipulation. Combining such facts with the doctrine of hereditary transmission, we reach a theory of Instinct. A chick, after coming out of the egg, balances itself correctly, runs about, picks up food, thus showing that it possesses a power of directing its movements to definite ends. How did the chick learn this very complex co-ordination of eye, muscles, and beak? It has not been individually taught; its personal experience is *nil;* but it has the benefit of ancestral experience. In its inherited organization are registered all the powers which it displays at birth. So also as regards the instinct of the hive-bee, already referred to. The distance at which the insects stand apart when they sweep their hemispheres and build their cells is "organically remembered." Man also carries with him the physical texture of his ancestry, as well as the inherited intellect bound up with it. The defects of intelligence during infancy and youth are probably less due to a lack of individual experience than to the fact that in early life the cerebral organization is still incomplete. The period necessary for completion varies with the race and with the individual. As a round shot outstrips a rifled one on quitting the muzzle of the gun, so the lower race in childhood may outstrip the higher. But the higher eventually overtakes the lower, and surpasses it in range. As regards individuals, we do not always find the precocity of youth prolonged to mental power in maturity; while the dulness of boyhood is sometimes strikingly contrasted with the intellectual energy of after-years. Newton, when a boy, was weakly, and he showed no particular aptitude at school; but in his eighteenth year he went to Cambridge, and soon afterwards astonished his teachers by his power of dealing with geometrical problems. During his quiet youth his brain was slowly preparing itself to be the organ of those energies which he subsequently displayed.

By myriad blows (to use a Lucretian phrase) the image and superscription of the external world are stamped as states of consciousness upon the organism, the depth of the impression depending upon the number of the blows. When two or more phenomena occur in the environment invariably together, they are stamped to the same depth or to the same relief, and indissolubly connected. And here we come to the threshold of a great question. Seeing that he could in no way rid himself of the consciousness of Space and Time, Kant assumed them to be necessary "forms of thought," the moulds and shapes into which our intuitions are thrown, belonging to ourselves solely and without objective existence. With unexpected power and success Mr. Spencer brings the hereditary experience theory, as he holds it, to bear upon this question. "If there exist certain external relations which are experienced by all organisms at all instants of their waking lives—relations which are absolutely constant and universal—there will be established answering internal relations that are absolutely constant and universal. Such relations we have in those of Space and Time. As the substratum of all other relations of the Non-Ego, they must be responded to by conceptions that are the substrata of all other relations in the Ego. Being the constant and infinitely repeated elements of thought, they must become the automatic elements of thought—the elements of thought which it is impossible to get rid of—the 'forms of intuition.'"

Throughout this application and extension of the "Law of Inseparable Association," Mr. Spencer stands on totally different ground from Mr. John Stuart Mill, invoking the registered experiences of the race instead of the experiences of the individual. His overthrow of Mr. Mill's restriction of experience is, I think, complete. That restriction ignores the power of organizing experience furnished at the outset to each individual; it ignores the different degrees of this power possessed by different races and by different individuals of the same race. Were there not in the human brain a potency antecedent to all experience, a dog or cat ought to be as capable of education as a man. These predetermined internal relations are independent of the experiences of the individual. The human brain is the "organized register of infinitely numerous experiences received during the evolution of life, or rather during the evolution of that series of organisms through which the human organism has been reached. The effects of the most uniform and frequent of these experiences have been successively bequeathed, principal and interest, and have slowly mounted to that high intelligence which lies latent in the brain of the infant. Thus it happens that the European inherits from twenty to thirty cubic inches more of brain than the Papuan. Thus it happens that faculties, as of music, which scarcely exist in some inferior races, become congenital in superior ones. Thus it happens that out of savages unable to count up to the number of their fingers, and speaking a language containing only nouns and verbs, arise at length our Newtons and Shakespeares."

At the outset of this Address it was stated that physical theories which lie beyond experience are derived by a process of abstraction from experience. It is instructive to note from this point of view the successive introduction of new conceptions. The idea of the attraction of gravitation was preceded by the observation of the attraction of iron by a magnet, and of light bodies by rubbed amber. The polarity of magnetism and electricity appealed to the senses; and thus became the substratum of the conception that atoms and molecules are endowed with definite, attractive and repellent poles, by the play of which definite forms of crystalline architecture are produced. Thus molecular force becomes *structural.* It required no great boldness of thought to extend its play into organic nature, and to recognize in molecular force the agency by which both plants and animals are built up. In this way out of experience arise conceptions which are wholly ultra-experimental.

The *origination* of life is a point lightly touched upon, if at all, by Mr. Darwin and Mr. Spencer. Diminishing gradually the number of progenitors, Mr. Darwin comes at length to one "primordial form;" but he does not say, as far as I remember, how he supposes this form to have been introduced. He quotes with satisfaction the words of a celebrated author and divine who had "gradually learned to see that it is just as noble a conception of the Deity to believe He created a few original forms, capable of self-development into other and needful forms, as to believe that He required a fresh act of creation to supply the voids caused by the action of His laws." What Mr. Darwin thinks of this view of the introduction of life I do not know. Whether he does or does not introduce his "primordial form" by a creative act I do not know. But the question will inevitably be asked, "How came the form there?" With regard to the diminution of the number of created forms, one does not see that much advantage is gained by it. The anthropomorphism, which it seemed the object of Mr. Darwin to set aside, is as firmly associated with the creation of a few forms as with the creation of a multitude. We need clearness and thoroughness here. Two courses and two only are possible. Either let us open our doors freely to the conception of creative acts, or abandoning them let us radically change our notions of Matter. If we look at matter as pictured by Democritus, and as defined for generations in our scientific text-books, the absolute impossibility of any form of life coming out of it would be sufficient to render any other hypothesis preferable; but the definitions of matter given in our text-books were intended to cover its purely physical and mechanical properties. And taught as we have been to regard these definitions as complete, we naturally and rightly reject the monstrous notion that out of *such* matter any form of life could possibly arise. But are the definitions complete? Everything depends on the answer to be given to this question. Trace the line of life backwards, and see it approaching more and more to what we call the purely physical condition. We reach at length those organisms which I have compared to drops of oil suspended in a mixture of alcohol and water. We reach the *protogenes* of Haeckel, in which we have "a type distinguishable from a fragment of albumen only by its finely granular character." Can we pause here? We break a magnet and find two poles in each of its fragments. We continue the process of breaking, but however small the parts, each carries with it, though enfeebled, the polarity of the whole. And when we can break no longer, we prolong the intellectual vision to the polar molecules. Are we not urged to do *something* similar in the case of life? Is there not a temptation to close to some extent with Lucretius, when he affirms that "Nature is seen to do all things spontaneously of herself without the meddling of the gods"? or with Bruno, when he declares that Matter is not "that mere empty *capacity* which philosophers have pictured her to be, but the universal mother who brings forth all things as the fruit of her own womb"? The questions here raised are inevitable. They are approaching us with accelerated speed, and it is not a matter of indifference whether they are introduced with reverence or with irreverence. Abandoning all disguise, the confession that I feel bound to make before you is that I prolong the vision backward across the boundary of the experimental evidence, and discern in that Matter, which we in our ignorance, and notwithstanding our professed reverence for its Creator, have hitherto covered with opprobrium, the promise and potency of every form and quality of Life.

The "materialism" here enunciated may be different from what you suppose, and I therefore crave your gracious patience to the end. "The question of an external world," says Mr. J. S. Mill, "is the great battle-ground of metaphysics."* Mr. Mill himself reduces external phenomena to "possibilities of sensation." Kant, as we have seen, made time and space "forms" of our own intuitions. Fichte, having first by the inexorable logic of his understanding proved himself to be a mere link in that chain of eternal causation which holds so rigidly in nature, violently broke the chain by making nature, and all that it inherits, an apparition of his own mind.† And it is by no means easy to combat such notions. For when I say I see you, and that I have not the least doubt about it, the reply is, that what I am really conscious of is an affection of my own retina. And if I urge that I can check my sight of you by touching you, the retort would be that I am equally transgressing the limits of fact; for what I am really conscious of is, not that you are there, but that the nerves of my hand have undergone a change. All we hear, and see, and touch, and taste, and smell, are, it would be urged, mere variations of our own condition, beyond which, even to the extent of a hair's breadth, we cannot go. That anything answering to our impressions exists outside of ourselves is not a *fact*, but an *inference*, to which all validity would be denied by an idealist like Berkeley, or by a sceptic like Hume. Mr. Spencer takes another line. With him, as with the uneducated man, there is no doubt or question as to the existence of an external world. But he differs from the uneducated, who think that the world really *is* what consciousness represents it to be. Our states of consciousness are mere *symbols* of an outside entity which produces them and determines the order of their succession, but the real nature of which we can never know.‡ In fact, the whole process of evolution is the manifestation of a Power absolutely inscrutable to the intellect of man. As little in our day as in the days of Job can man by searching find this Power out. Considered fundamentally, it is by the operation of an insoluble mystery that life is evolved, species differentiated, and mind unfolded from their prepotent elements in the immeasurable past. There is, you will observe, no very rank materialism here.

The strength of the doctrine of evolution consists, not in an experimental demonstration (for the subject is hardly accessible to this mode of proof), but in its general harmony with the method of nature as hitherto known. From contrast, moreover, it derives enormous relative strength. On the one side we have a theory (if it could with any propriety be so called) derived, as were the theories referred to at the beginning of this Address, not from the study of nature, but from the observation of men—a theory which converts the Power whose garment is seen in the visible universe into an Artificer, fashioned after the human model, and acting by broken efforts, as man is seen to act. On the other side we have the conception that all we see around us, and all we feel within us—the phenomena of physical nature as well as those of the human mind—have their unsearchable roots in a cosmical life, if I dare apply the term, an infinitesimal span of which only is offered to the investigation of man. And even this span is only knowable in part. We can trace the development of a nervous system, and correlate with it the parallel phenomena of sensation and thought. We see with undoubting certainty that they go hand in hand. But we try to soar in a vacuum the moment we seek to comprehend the connexion between them. An Archimedean fulcrum is here required which the human mind cannot command; and the effort to solve the problem, to borrow an illustration from an illustrious friend of mine, is like the effort of a man trying to lift himself by his own waistband. All that has been here said is to be taken in connexion with this fundamental truth. When "nascent senses" are spoken of, when "the differentiation of a tissue at first vaguely sensitive all over" is spoken of, and when these processes are associated with "the modification of an organism by its environment," the same parallelism, without contact, or even approach to contact, is implied. There is no fusion possible between the two classes of facts—no motor energy in the intellect of man to carry it without logical rupture from the one to the other.

Further, the doctrine of evolution derives man, in his totality, from the interaction of organism and environment through countless ages past. The Human Understanding, for example—that faculty which Mr. Spencer has turned so skilfully round upon its own antecedents—is itself a result of the play between organism and environment through cosmic ranges of time. Never surely did prescription plead so irresistible a claim. But then it comes to pass that, over and above his understanding, there are many other things appertaining to man whose prescriptive rights are quite as strong as that of the understanding itself. It is a result, for example, of the play of organism and environment that sugar is sweet and that aloes are bitter, that the smell of henbane differs from the perfume of a rose. Such facts of consciousness (for which, by the way, no adequate reason has ever yet been rendered) are quite as old as the understanding itself; and many other things can boast an equally ancient origin. Mr. Spencer at one place refers to that most powerful of passions—the amatory passion—as one which, when it first occurs, is antecedent to all relative expe-

* 'Examination of Hamilton,' p. 154.

† 'Bestimmung des Menschen.'

‡ In a paper, at once popular and profound, entitled 'Recent Progress in the Theory of Vision,' contained in the volume of Lectures by Helmholtz, published by Longmans, this symbolism of our states of consciousness is also dwelt upon. The impressions of sense are the mere *signs* of external things. In this paper Helmholtz contends strongly against the view that the consciousness of space is inborn; and he evidently doubts the power of the chick to pick up grains of corn without some preliminary lessons. On this point, he says, further experiments are needed. Such experiments have been since made by Mr. Spalding, aided, I believe, in some of his observations by the accomplished and deeply lamented Lady Amberley; and they seem to prove conclusively that the chick does not need a single moment's tuition to teach it to stand, run, govern the muscles of its eyes, and peck. Helmholtz, however, is contending against the notion of pre-established harmony; and I am not aware of his views as to the organization of experiences of race or breed.

rience whatever; and we may pass its claim as being at least as ancient and as valid as that of the understanding itself. Then there are such things woven into the texture of man as the feeling of awe, reverence, wonder, and not alone the sexual love just referred to, but the love of the beautiful, physical and moral, in Nature, Poetry, and Art. There is also that deep-set feeling which, since the earliest dawn of history, and probably for ages prior to all history, incorporated itself in the religions of the world. You who have escaped from these religions into the high and-dry light of the understanding may deride them; but in so doing you deride accidents of form merely, and fail to touch the immovable basis of the religious sentiment in the emotional nature of man. To yield this sentiment reasonable satisfaction is the problem of problems at the present hour. And grotesque in relation to scientific culture as many of the religions of the world have been and are—dangerous, nay, destructive, to the dearest privileges of freemen as some of them undoubtedly have been, and would, if they could, be again—it will be wise to recognize them as the forms of a force, mischievous, if permitted to intrude on the region of *knowledge*, over which it holds no command, but capable of being guided by liberal thought to noble issues in the region of *emotion*, which is its proper sphere. It is vain to oppose this force with a view to its extirpation. What we should oppose, to the death if necessary, is every attempt to found upon this elemental bias of man's nature a system which should exercise despotic sway over his intellect. I do not fear any such consummation. Science has already to some extent leavened the world, and it will leaven it more and more. I should look upon the mild light of science breaking in upon the minds of the youth of Ireland, and strengthening gradually to the perfect day, as a surer check to any intellectual or spiritual tyranny which might threaten this island, than the laws of princes or the swords of emperors. Where is the cause of fear? We fought and won our battle even in the Middle Ages: why should we doubt the issue of a conflict now?

The impregnable position of science may be described in a few words. All religious theories, schemes, and systems which embrace notions of cosmogony, or which otherwise reach into its domain, must, in so far as they do this, submit to the control of science, and relinquish all thought of controlling it. Acting otherwise proved disastrous in the past, and it is simply fatuous to-day. Every system which would escape the fate of an organism too rigid to adjust itself to its environment, must be plastic to the extent that the growth of knowledge demands. When this truth has been thoroughly taken in, rigidity will be relaxed, exclusiveness diminished, things now deemed essential will be dropped, and elements now rejected will be assimilated. The lifting of the life is the essential point; and as long as dogmatism, fanaticism, and intolerance are kept out, various modes of leverage may be employed to raise life to a higher level. Science itself not unfrequently derives motive power from an ultra-scientific source. Whewell speaks of enthusiasm of temper as a hindrance to science; but he means the enthusiasm of weak heads. There is a strong and resolute enthusiasm in which science finds an ally; and it is to the lowering of this fire, rather than to a diminution of intellectual insight, that the lessening productiveness of men of science in their mature years is to be ascribed. Mr. Buckle sought to detach intellectual achievement from moral force. He gravely erred; for without moral force to whip it into action, the achievements of the intellect would be poor indeed.

It has been said that science divorces itself from literature: the statement, like so many others, arises from lack of knowledge. A glance at the less technical writings of its leaders—of its Helmholtz, its Huxley, and its Du Bois-Reymond—would show what breadth of literary culture they command. Where among modern writers can you find their superiors in clearness and vigour of literary style? Science desires not isolation, but freely combines with every effort towards the bettering of man's estate. Single-handed, and supported not by outward sympathy, but by inward force, it has built at least one great wing of the many-mansioned home which man in his totality demands. And if rough walls and protruding rafter-ends indicate that on one side the edifice is still incomplete, it is only by wise combination of the parts required with those already irrevocably built that we can hope for completeness. There is no necessary incongruity between what has been accomplished, and what remains to be done. The moral glow of Socrates, which we all feel by ignition, has in it nothing incompatible with the physics of Anaxagoras, which he so much scorned, but which he would hardly scorn to-day. And here I am reminded of one amongst us, hoary, but still strong, whose prophet-voice some thirty years ago, far more than any other of this age, unlocked whatever of life and nobleness lay latent in its most gifted minds—one fit to stand beside Socrates or the Maccabean Eleazar, and to dare and suffer all that they suffered and dared—fit, as he once said of Fichte, "to have been the teacher of Stoa, and to have discoursed of Beauty and Virtue in the groves of Academe." With a capacity to grasp physical principles which his friend Goethe did not possess, and which even total lack of exercise has not been able to reduce to atrophy, it is the world's loss that he, in the vigour of his years, did not open his mind and sympathies to science, and make its conclusions a portion of his message to mankind. Marvellously endowed as he was—equally equipped on the side of the Heart and of the Understanding—he might have done much towards teaching us how to reconcile the claims of both, and to enable them in coming times to dwell together in unity of spirit and in the bond of peace.

And now the end is come. With more time, or greater strength and knowledge, what has been here said might have been better said, while worthy matters here omitted might have received fit expression. But there would have been no material deviation from the views set forth. As regards myself, they are not the growth of a day; and as regards you, I thought you ought to know the environment which, with or without your consent, is rapidly surrounding you, and in relation to which some adjustment on your part may be necessary. A hint of Hamlet's, however, teaches us all how the troubles of common life may be ended; and it is perfectly possible for you and me to purchase intellectual peace at the price of intellectual death. The world is not without refuges of this description; nor is it wanting in persons who seek their shelter and try to persuade others to do the same. I would exhort you to refuse such shelter, and to scorn such base repose—to accept, if the choice be forced upon you, commotion before stagnation, the leap of the torrent before the stillness of the swamp. In the one there is at all events life and, therefore, hope; in the other none. I have touched on debatable questions, and led you over dangerous ground—and this partly with the view of telling you, and through you the world, that as regards these questions science claims unrestricted right of search. It is not to the point to say that the views of Lucretius and Bruno, of Darwin and Spencer, may be wrong. Here I should agree with you, deeming it indeed certain that these views will undergo modification. But the point is, that, whether right or wrong, we claim the freedom to discuss them. The ground which they cover is scientific ground; and the right claimed is one made good through tribulation and anguish, inflicted and endured in darker times than ours, but resulting in the immortal victories which science has won for the human race. I would set forth equally the inexorable advance of man's understanding in the path of knowledge, and the unquenchable claims of his emotional nature which the understanding can never satisfy. The world embraces not only a Newton, but a Shakespeare—not only a Boyle, but a Raphael—not only a Kant, but a Beethoven—not only a Darwin, but a Carlyle. Not in each of these, but in all, is human nature whole. They are not opposed, but supplementary—not mutually exclusive, but reconcilable. And if, still unsatisfied, the human mind with the yearning of a pilgrim for his distant home, will turn to the Mystery from which it has emerged, seeking so to fashion it as to give unity to thought and faith, so long as this is done, not only without intolerance or bigotry of any kind, but with the enlightened recognition that ultimate fixity of conception is here unattainable, and that each succeeding age must be held free to fashion the mystery in accordance with its own needs—then, in opposition to all the restrictions of Materialism, I would affirm this to be a field for the noblest exercise of what, in contrast with the *knowing* faculties, may be called the *creative* faculties of man. Here, however, I must quit a theme too great for me to handle, but which will be handled by the loftiest minds ages after you and I, like streaks of morning cloud, shall have melted into the infinite azure of the past.

Parliamentary and Law Proceedings.

Conviction under the Pharmacy Act, 1868.

Mr. George Day, of No. 3, Farringdon Road, Clerkenwell, was summoned before Mr. Arnold, at the Clerkenwell Police Court, for an offence under the 17th section of the Pharmacy Act, 1868, by having sold oxalic acid without affixing the name of the article, and the name and address of the seller, to it.

The case was first brought before the magistrate on Wednesday, the 5th inst.; but, as the accused was not present, the summons was adjourned until the 12th, when Mr. Flux appeared for the prosecution. The accused was undefended.

Mr. Flux opened the case, explaining the circumstances to the magistrate, and commenting upon the section of the Act infringed, and said, as he did not wish to occupy the time of the Court, he would at once call William West.

The accused here interposed, and protested against his own servant being called against him, but the magistrate said, as he was called, he must give evidence or he would be committed.

William West was then sworn. He deposed that he was the manager of the shop, at No. 3, Farringdon Road—that the business belonged to Mr. Day, that he (Mr. Day) resided at the Clerkenwell public-house, three doors from the shop, and that he remembered selling the poison on the 4th of this month. Cross-examined by the accused, said that he had been thirty years in the profession, and considered he was perfectly qualified to manage the shop. Re-examined, said that he was not on the Register of Chemists and Druggists.

Mr. Ward, clerk to Messrs. Flux and Co., deposed to having, on the 4th August, purchased at the shop, at No. 3, Farringdon Road, a packet of oxalic acid which he produced; it bore the name of a Mr. Howse, and the address, 29, Exmouth street, Clerkenwell.

Dr. Redwood, Professor of Chemistry to the Pharmaceutical Society and public analyst for Clerkenwell, proved the analysis of the packet, and that it was oxalic acid.

Mr. Flux then addressed the magistrate, saying that the prosecution was instituted solely for the protection of the public, and to restrain unqualified persons from carrying on the business of a chemist and druggist, and without any vindictive feelings at all.

The accused then said that he admitted that the shop belonged to him. He was a contractor, and had a large property there, and he had taken the shop from the previous occupier to save himself from loss, and in the agreement was a clause authorizing him to use the name of Mr. Howse. He had since moved the shop from 29, Exmouth street, to 3, Farringdon Road, three doors off. If he had done wrong it was unwittingly.

Mr. Flux here put in a correspondence which had passed between Mr. Bremridge, the Registrar appointed under the provisions of the Pharmacy Act, 1868, and the accused, showing that, as far back as November last, he had been warned that he was carrying on the business illegally.

In the end the magistrate said that there had evidently been a breach, but he thought it was not a fraudulent one, and, therefore, he should bind the accused over in his own recognizances to come up for judgment when called upon.

BOOKS RECEIVED.

Tea, Coffee, and Cocoa. A Practical Treatise on the Analysis of Tea, Coffee, Cocoa, Chocolate, Maté (Paraguay Tea), etc. By J. Alfred Wanklyn, M.R.C.S., etc. London: Trübner and Co. 1874. From the Author.

Materia Medica and Therapeutics. Vegetable Kingdom. By Charles D. F. Phillips, M.D., F.R.C.S.E. London: J. and A. Churchill. 1874. From the Author.

Nouveau Dictionnaire des Falsifications et des Altérations des Aliments, des Médicaments et de quelques Produits employés dans les Arts, l'Industrie et l'Économie domestique. Par J. Léon Soubeiran. Paris: J. B. Baillière et fils. 1874. From the Author.

Obituary.

Notice has been received of the death of the following:—

On the 30th July, 1874, Mr. Henry Brooke Muriel, Pharmaceutical Chemist, of Wentworth Street, Brighton. Mr. Muriel was one of the founders of the Pharmaceutical Society.

On the 2nd March, 1874, Mr. William Goodess, Chemist and Druggist, of Leicester.

On the 4th July, 1874, Mr. W. H. J. Ford, Chemist and Druggist, of Shiffnal.

On the 11th July, 1874, Mr. Walter T. W. Elkington, Chemist and Druggist, of Leicester.

On the 11th July, 1874, Mr. Robert Durden, Chemist and Druggist, of Fulham Road, London.

On the 17th July, 1874, Mr. John P. Cadby, Chemist and Druggist, of Margate.

On the 28th July, 1874, Mr. Joseph James Harrison, Chemist and Druggist, of Market Harborough. Mr. Harrison had been an Associate of the Society since 1869.

On the 29th July, 1874, Mr. Sedgwick Hodgkinson Cooper, Chemist and Druggist, of West Hartlepool.

On the 1st August, 1874, Mr. Joseph Steele Smith, Chemist and Druggist, of Westminster.

On the 5th August, 1874, Mr. B. L. Burrows, Chemist and Druggist, of Norwich.

On the 5th August, Mr. Thomas Dunlop, Chemist and Druggist, of Newcastle-on-Tyne. Mr. Dunlop was recently elected an Associate of the Pharmaceutical Society.

On the 5th of August, 1874, Mr. Thomas Hall Dunlop, Chemist and Druggist, of Newcastle-on-Tyne.

On the 8th August, 1874, Mr. George Noble, Chemist and Druggist, of Hull.

Notes and Queries.

"AUREOLINE."—Will any correspondent kindly furnish me with a formula for a golden hair-dye, so extensively used at the present time?—Querist.

Can any reader oblige by informing me how I can dye brown or auburn hair, a light golden colour.—F. A. B.

Correspondence.

THE SESSIONAL PRIZES.

Sir,—I observed, with not a little surprise, in the last number of your Journal, that the Council in London had awarded the "£2 Prize of Books" to a candidate who also carried off the "Pereira Medal." Now as the Book Prize is intended for those who have passed the "Minor Examination" in honours, while the Medal is attainable only by those taking honours in the "Major," it surely follows that anyone attempting the higher honour should render himself ineligible in the same year to compete for the lesser one, thus depriving many a deserving youth of the prize he had hoped for, and who probably had worked harder for the same end than the student fresh from Bloomsbury Square, after a training of several sessions of college tuition under learned professors.

Further, I think it is scarcely just that the competition is only open to candidates who present themselves in London or Edinburgh, after so many centres have been made for conducting the "Preliminary," and both are written Examinations: thus again throwing a great obstacle in the way of country Associates, who have little encouragement to pursue their studies, and still less opportunity of testing their knowledge, and who, though willing and possibly quite as able as their more advantageously situated friends, are deprived of the trial in so far as no sensible person would risk travelling expenses (which might exceed the value of the prize) on merely a chance of success. Apologizing for occupying so much of your space, I am, etc.,

August 12th, 1874. FAIRPLAY.

THE LADIES' CLOAK-ROOM.

Sir,—Will you allow me to say a few words on behalf of myself and my fellow students in regard to the obstacle which at present bars our entrance to the laboratory of the Pharmaceutical Society at Bloomsbury Square, namely, the absence of a ladies' cloak-room. We quite agree with Mr. Sandford, that the privacy of the porter's bedroom should not be invaded; at the same time we are willing—without a murmur or reproach against the courtesy of the Pharmaceutical Society—to dispense altogether with a cloak room. If obliged to divest ourselves of cloaks and bonnets before entering the laboratory, we will gladly, if allowed, hang them up in the hall, or if that be not permitted, we will bear them on our backs and heads. In the present day, fashion does not inconvenience ladies with large and handsome cloaks, and as to bonnets, our aching heads puzzling over the mysteries of tests, precipitates, and crystallization, can scarcely be aware of their presence or absence.

We earnestly trust that a matter of detail so unimportant to the persons interested, will not be allowed to prevent us and other lady students from taking the best means to obtain the education we desire.

August 12th, 1874. ALICE HART.

THE OILS OF CHINESE PHARMACY AND COMMERCE.

Sir,—In reply to Mr. D. Hanbury, I beg to say that the statement that cassia oil is obtained by distillation from the leaves and twigs of the cassia tree is not the result of personal observation, but is based upon a statement of Dr. S. W. Williams, long a resident at Canton. He is now Chinese Secretary at the American Legation, Peking.

The oleum malabathri thus made has beeen so named from the old name of the leaves of the *Cinnamomum tamala*, called folia tamalapathri, shortened and corrupted into folia malabathri.

These folia malabathri were formerly exported from Canton, and, like many Chinese exports (such as "Indian ink," "India paper"), were sent to Western ports as the "Indian leaf." The oil has apparently taken the place of the leaves and been named after them. If Mr. Hanbury will refer to page 196 of Dr. Waring's 'Pharmacopœia of India,' London, 1868, or to page 113 of the fifth edition of the 'Chinese Commercial Guide' of Dr. S. W. Williams, he will find some account of the oil and leaves. Absence from home must be my apology for so late a reply.

Shepton Mallet, August 14th, 1873. F. PORTER SMITH.

W. F. Caunt.—A recipe for a cement for india-rubber was given in the *Pharmaceutical Journal* for January 31st last, p. 628.

W. Bill.—The reason why so many failed in the July examination is obvious. An unusually large number of young men presented themselves, either wholly unprepared, or entirely ignorant of the nature of the examination. They were doubtless induced to appear in consequence of the alteration in the examinations that will come into force in October next.

"*Minor.*"—(1) The works mentioned are among the best for the purpose, but it would be injudicious to confine your reading to one author on each subject. (2) 'Deschanel's Natural Philosophy,' or 'Ganot's Physics.'

W. Adams.—(1) *Aristolochia longa.* (2) *Acacia scandens.*

W. W. W.—You will find the subjects of the examination stated in the Regulations of the Board of Examiners, a copy of which may be obtained from the Secretary. We do not know that the questions have any relation to particular pages in the work mentioned.

W. H.—The Botanical Prize for the present year has been awarded; but one has been announced for 1875, information respecting which will be found in the *Pharmaceutical Journal* for April 25th last, p. 857.

H. Bennett.—No distinction between the sexes is made in the terms of the Arsenic Act.

"*Smilax.*"—There can be no doubt that the label sent would render a stamp necessary, because it recommends a certain preparation as a remedy for the cure or relief of disease, and also represents it to be a secret preparation.

F. W. H.—For full particulars you are referred to the Pharmacy Act, 1868.

M. G.—Apply to Mr. Gerrard, University College Hospital, Gower Street, W.C.

Frank Long, Murree, Punjab.—Mix the ingredients well together, avoiding the use of spirit in powdering the camphor, and add six grains of light calcined magnesia. On mixing well again, the mass will be found sufficiently hard and plastic to be rolled out easily into pills, which will retain their shape and take the silver readily. Avoid the use of more magnesia or the pills will be insoluble. The hard kind of assafœtida, should, of course, be selected for such a pill mass.

T. G. T.—The reaction would consist mainly in the reduction of the sulphuric acid, and the production of sulphurous and carbonic acids.

W. Bartholomew.—The mixture will have a precipitate and require shaking.

G. C. Druce.—We thank you for the account of the botanical ramble of the Northampton Pharmaceutical Association on the 15th May last, but are unable to avail ourselves of your kindness in consequence of the pressure of more recent matters.

H. G. R.—Probably Cooley's 'Cyclopædia of Practical Receipts,' the fifth edition of which, edited by Professor Tuson, was published in 1872, by J. and A. Churchill.

"*A Reader.*"—The particulars respecting the Library are published weekly among the official notices on the cover of the Journal.

J. Tomlinson.—Such a person not being an Associate of the Pharmaceutical Society would not be allowed to call himself one.

"*Student.*"—No certificate is given.

Exhibition of Objects relating to Pharmacy.—We have received a letter from Messrs. Roberts and Co., of New Bond Street, stating that the articles shown under their name in the above exhibition were sent from their London house, and that their Paris house was not represented. Merely from the note-heading and envelope used in this communication we should have thought the firms were identical, and that any correction of our report was unnecessary.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Allen, Mr. Hoffmann, Mr. Attenburrow, Mr. W. H. Symons, Mr. R. J. Shields, Mr. Roberts, Mr. Ireland, H. C., H. G. R., W. W., "Echo," "Ignoramus."

AUSTRALIAN JOTTINGS.

BY T. H. HUSTWICK.

It is a remark frequently made by fresh arrivals that, at first sight, the city of Melbourne presents very much of an English appearance; this impression, however, is gradually removed as the acquaintance becomes extended, and many details are brought to view which cannot fail to remind a "new chum" that though in a city of the British empire, he is not in Great Britain. A walk through the streets of Melbourne shows us, for instance, shops of all kinds and sizes, as thoroughly English in appearance as any in London or Liverpool, public buildings as extensive and imposing, and municipal institutions in full operation. Extend the walk beyond the line of shops, note the one-storied houses, with the lavish growth of passion-flower or jasmine clothing the verandah, and even the roof with their wealth of bloom and cool green foliage; perfumes unusual to English senses salute us as we pass, from myrtle, orange, and others of like fragrance; in the garden fences the prickly pear is conspicuous by its eccentric growth and forbidding spines; rising from the lawn of the trim villa is the Norfolk Island pine, most perfect and symmetrical of its species; elsewhere a beautiful palm raises its head of dark green above the surrounding shrubs, and here and there, in favoured spots, one comes across a lovely tree fern, characteristic of this southern land. Soon—perhaps too soon—the eye becomes accustomed to these new sights, and we turn to sights and occupations more in accord with our home feelings and experience. Among other trades and professions carried on here, that of the chemist and druggist occupies, as at home, a prominent position; to enter a druggist's shop is to an old hand to feel at home; all seems exactly similar to that which he has but lately left, even to the well-known diploma of the Pharmaceutical Society of Great Britain, and it is no exaggeration to say that the better shops of this kind in Melbourne can hold their own against many well-known London houses, either for excellence of appointments, amount and variety of stock, or skill and reputation of the proprietor. With much to commend, there is also that which should be contemned. Late into the night many red lamps and illuminated interiors show that the druggist competes with the tobacconist and others of that class for the last possible shilling of the day's trade, and on Sundays the shop-door kept half open throughout the day reveals the fact that the English institution of late hours and Sunday trade is in a flourishing state. In the country the case is not so bad; there the druggist can afford to dispense with these accessories; often he has no competitor for miles, perhaps within half a day's ride; as a consequence, a mutual understanding between him and his customers is in existence. As it was "up the country" where the writer first made acquaintance with Australian pharmacy, while on a visit to a relative engaged in the trade, perhaps a few words in regard to that aspect of it may not be out of place. Prior to this, a journey of 150 miles had to be accomplished, chiefly by coach. Of the incidents connected therewith this is not exactly the place to speak, save that to witness a sunrise in the bush, with its concomitant awakening of animal life, and to inhale the delicious odours exhaled by countless eucalyptus trees under the influence of the early sun, together with the novel and varied scenery gradually unfolded to our view, was more than sufficient compensation for a night spent inside a stage-coach. The establishment required by a country druggist need not be either elaborate or extensive. Provided he has a fair amount of room for his "fixings," he requires no display, for it is not by such that he will succeed; his reputation, for good or evil will spread rapidly enough from within. He must be steady, competent, handy at other acquirements than those of his own business, good at prescribing, dentistry, and minor surgery, able to perform such an operation as Halford's ammonia-injection for snake bite, and competent, on a pinch, to act as *locum tenens* to the doctor during illness or temporary absence. For the exercise of these faculties he is rewarded with a liberality unknown to many a practitioner at home, and with a cheerfulness surprising to a stranger. In dispensing too, he does well, seldom taking less than double the home prices, and often exceeding that. He need not be particular as to the style in which he sends out his medicines; any kind of a bottle, wine or beer, will do if clean, as medicine bottles are scarce and dear in the bush, costing much in carriage. White demy is not often used, except to fold powders in; an old newspaper will hide the shape and contents of the bottle as well as any other kind, neither is a boy requisite to carry out the physic in a neat basket; if the customers cannot come or send at the time, why, they just wait till they can. On the whole the life of an "up country" druggist is not an unpleasant one; business is generally prosperous; he is not eternally tied down to his counter; can shut up at dark; with a little management can get a day's shooting, fishing, or kangarooing, now and then, without business suffering, for if his intention be made known beforehand, customers are compliant, and do not grudge a holiday now and then. From his generally superior education, he is able to take a leading position amongst those around him, while, if steady in habits and clever in business, he commands a reputation over a wide extent of country. In the larger towns, the chemist's experience is much the same as at home, but though hampered by long hours and Sunday trade, competition is not so ruinously keen; though rents and expenses are high, he obtains good prices for his goods and services; purchases, too, are made for larger amounts than at home, the shilling usually being the unit of purchase-money. Altogether, I think the position of the chemist and druggist here superior to that at home. It is his own fault that he keeps unreasonable hours; he is better remunerated in every way, while the trade and payments have not, and I think are not likely to assume the contemptible proportions they so often present in many English towns; diligence and sobriety find a speedy reward, and to men of a scientific turn of mind, a congenial opening is often presented by the demands of mining pursuits, and the opening out of new industries where a knowledge of chemistry is desirable. When the Colonial Pharmacy Act becomes law its benefits will be as much appreciated as those of the English Act were; chief of them will be that clause confining the sale of poisons, which is something enormous, to its proper channels. Did time and space permit, I could give instances of the imperative necessity for such legislation. The remuneration of assistants is on a corresponding liberal scale, averaging quite double the home rate,—an ordinary hand receiving about £2 per week, indoors, occasionally rising to £3. I am informed that there is a steady demand for the services of English assistants, and my own observation is in favour of the assertion; indeed, no "new chum" in search of employment in our trade need be idle long if he can produce satisfactory evidence as to his capabilities and character; he will also find the possession of one or both of the certificates of the Pharmaceutical Society will be considerably to his benefit. The well-educated assistant, if scientifically inclined, will find much to engage his attention. If chemistry be his *forte*, the many compounds of the inorganic kingdom, in the way of mineral ores, will doubtless interest him; if a lover of botany, he will find an entirely new and gorgeous page of nature's book opened out to him; the study of zoology and entomology may abundantly occupy his leisure out of doors, while the microscope will afford the like solace for indoor leisure. What change could be more desirable for one wishful to enlarge his experience, or one weary of the anxieties of business at home, with its small and uncertain results, and the constant strain on the mind from the daily endeavours to make both ends meet, than to come to one of these antipodean colonies, where with a fresh start past anxieties may be forgotten, and where all the surroundings are conducive to health of body and strength of mind?

The character of the drug trade in the colony is, of course, much the same as at home, and as I before remarked, in the larger towns shops are found as elegantly fitted and as well supplied as there. Judging from the quantity of patent medicines sold, I imagine the consumption per head of the population to be very much greater than in England, and they form a considerable portion of the stock of nearly every country storekeeper, who, besides these and many domestic remedies, deals in such things as arsenic and strychnia, which are often purchased in large quantities by squatters for checking the ravages of the "dingo," or native dog, among their flocks. In addition to the well-known English cure-alls the colony is flooded with American nostrums, many of which are perhaps hardly known at home; these have an immense sale, and, considering their high prices, must be very remunerative to their proprietors. Another peculiarity of colonial pharmacy is the large trade in American herbs. Here at Sandhurst we keep in stock over a hundred varieties. They are prepared chiefly at Boston, and are sent out in a compressed state, roots, barks, and herbs, and are patterns of preservation, the colour and aroma of each parcel, even after the lapse of many months, being all that can be desired. The principal demand for these is from the "Spiritists" and Coffinites; of the former class, there is one practising as a physician in Melbourne, whose advice is sought far and wide, and who enjoys a degree of fame attained by but few of the legitimate profession; his manner of proceeding, I am told, is as follows:—All communications must be in writing, and contain, besides a lock of the patient's hair, a statement of his or her age, sex, and occupation—no symptoms need to be detailed, as the spirits supply all necessary information to their medium, the physician, who, in due time, forwards to the sufferer a paper containing a full description of the malady and the organs implicated therein. As pretty nearly every function of the body is mentioned in each case as being disordered, the probability is that the right one is included. Then follow the prescriptions, usually two, for herbal infusions and decoctions, concluding with a few directions as to diet, living, etc., the latter seemingly the most sensible part of the lot. Many of these prescriptions have come under my notice, and there is a very suspicious sameness throughout. It is by no means essential to be a believer in Spiritualism to enjoy these benefits, but it must require a large amount of gullibility and a capacity for swallowing any amount of nauseous physic not usually met with among enlightened people. Still, I am informed that many wonderful cures have been effected under the system, even after the treatment of the "schools," as Dr. Coffin says, has failed to produce benefit. For those who are curious in such matters, I enclose copies of some of these prescriptions; perhaps some of your readers who suffer from the symptoms here detailed may take a hint.

"Imperfect action of liver, stomach, and excretory functions, unhealthy condition of blood, derangement of reproductive organs, and want of nervous tone.

Remedy No. 1.

Infuse ½ oz. each—Agrimony, balmony, and bayberry in 1½ pints of boiling water.

Dose—a wine-glassful twice a day on an empty stomach.

No. 2.

Infuse—

Goldenseal	¼ oz.
Bittersweet	¼ "
Blue Cohoch	¼ "
Senna	1 dr.
Pennyroyal	3 drs.

in a pint of boiling water.

Dose—a large wine-glassful at bed-time.

Diet—Light and easy of digestion. As little slop as possible."

"Weakness of the lungs and pleura, spleen torpid, imperfect action of the liver, digestive and excretory functions, weakness in reproductive organs and lumbar-region, debility of blood, and want of nervous tone.

Remedy No. 1.

Put ¾ oz. of sassafras, ¼ oz. composition in 1½ pints of water, boil fifteen minutes and strain.

Dose—a large wine-glassful in warm milk early in the morning.

No. 2.

Infuse ¾ oz. red centaury in ¾ pint of boiling water; when cool, add a glass of good rum.

Dose—a wine-glassful at mid-day.

No. 3.

Infuse—

Blue Cohoch	¼ oz.
Dittany	¼ "
Elecampane	¼ "
Blood Root	¼ "
Mandrake	1 dr.

in a pint of boiling water.

Dose—A large wine-glassful at bed-time.

Take a warm sitz bath twice a week.

Diet—Light and easy of digestion—not much tea or other hot slop."

"The singing in the head cannot be cured except by a long course of mesmeric treatment, but the symptoms may be modified. The action of the liver, digestive and excretory functions are imperfect and the circulation bad. I annex prescription:—

Remedy No. 1.

Put 1¼ oz. sassafras into 1½ pints of water, and boil fifteen minutes.

Dose—a large wine-glassful twice a day on an empty stomach.

No. 2.

Infuse ¼ oz. of each—Mandrake, bittersweet, black root. and chamomile in a pint of boiling water.

Dose—a large wine-glassful at bed-time.

Well rub the right side with oil of eucalyptus and olives for about ten minutes daily. Eat plenty of fresh grapes, avoid stimulants, and take as little hot slops as possible."

In conclusion, I would observe to those who think they may improve their position by emigration, that many British Colonies have attained the limits of their development, and are well supplied with various trades and professions. Australian colonization, wonderful in its past, will probably be yet more so in its future; new settlements and townships are continually springing up, railways rapidly opening out the resources of the country, and already the telegraph spans the continent from ocean to ocean. Besides all this, there is an extent of country practically unlimited yet to be peopled. Here are advantages possessed by no other colony of the same age, and many generations yet to come will bear witness to the fufilment of the sentiment embodied in the motto of this land, "Advance Australia!"

SYRUP OF BROMIDE OF IRON.

BY M. H. STILES, M.P.S.

I noticed in a recent number of the Journal a formula for syrup of bromide of iron, taken from a French paper on the subject. About six weeks ago I had occasion to prepare some of the syrup for a prescription. This was made to contain three grains of bromide of iron in each fl. ʒj., which, from inquiries I have since made, is the strength usually recommended in this country.

The syrup made by M. Prince is only about one-seventh this strength, and is scarcely in accordance with English ideas of what such a preparation should be. The following is the process I adopted :—

Take of—

Thin Iron Wire, free from rust . . .	½ oz.
Bromine	320 grs.
Distilled Water	1 oz.

Put the wire and water in an 8-oz. flask, the lower portion of which is placed in a vessel of cold water, add the bromine gradually, corking the flask after each addition, and taking care that one portion is nearly neutralized before another is poured in. When all the bromine has been added, heat the flask gently until the brown colour disappears, and filter the solution, whilst hot, through paper; wash the wire with a little distilled water, filter the washings, add them to the filtrate, and make the resulting liquid measure fl. ℥ij. Mix this with fl. ℥xvj. of syrup. One fluid-drachm contains three grains of $FeBr_2$.

If the flask be not kept cool, and the process controlled in the manner directed, the action becomes so violent that a considerable portion of the bromine is lost.

Bromide of iron is also given in combination with bromide of quinine or bromide of strychnia, or with both, the amount of these in fl. ʒj of the syrup being one grain and $\frac{1}{32}$ grain respectively.

Hull, July 27th, 1874.

CHEMICAL CONSTITUTION.*

BY A. CRUM BROWN, M.D., F.R.S.E., ETC.

One hundred years have elapsed since the discovery of oxygen by Priestley. Perhaps we should say re-discovery, for there is no doubt that about one hundred years earlier Mayow prepared from nitre nearly pure oxygen, and observed and recorded some of its most marked properties. Mayow's discovery, however, led to nothing; while Priestley's was the most important step in that reconstruction of speculative chemistry which was commenced by Black and carried on with surprising energy and thoroughness by Lavoisier and his associates. I shall not detain you by enumerating the ways in which this discovery has affected chemistry, both practical and speculative. The pre-eminent position to which oxygen was at once elevated, and which it so long retained, makes this altogether unnecessary. I wish, however, to point out one character of the phlogistic controversy, which sharply distinguishes it from many others. The truth represented by the theory of Phlogiston was not recognized with sufficient distinctness by the supporters of that theory to give them any chance of success in opposition to a band of devoted adherents of a view which was clearly understood by all. The Phlogistists were completely defeated, and the theory ceased to exist. It has been left for chemical antiquaries to pick out, with difficulty and uncertainty, a meaning from the ruins.

I have mentioned this character because I wish to draw your attention to another, more recent, controversy, the result of which was very different.

The questions as to chemical constitution, raised about forty years ago by Dumas and the new French school in opposition to Berzelius, may now be said to be practically settled. The great majority of chemists are agreed as to what is to be understood by chemical constitution, and also as to the nature and amount of evidence required in order to determine the constitution of a substance. How has this agreement been produced? Some historical writers seem to wish us to believe that it is the result of the triumph of the ideas of Dumas, Gerhardt, and Laurent, and the defeat of the dualistic radical theory of Berzelius; that the arguments of Berzelius and his followers were only useful as giving occasion for a more full and convincing proof of the unitary substitution theory than would otherwise have been called for; that, in fact, the adherents of dualism played the part (not unfrequently supposed to be that of the Conservative party in politics) of checking and criticizing the successive developments of truth, and thus allowing them time to ripen.

In opposition to the view thus broadly stated, I would place another, and, for the sake of contrast, shall state it also in perhaps too broad a form. That the two theories—the dualistic radical theory and the unitary substitution theory—were both true and both imperfect; that they underwent gradual development, scarcely influenced by each other, until they have come to be almost identical in reference to points where they at one time seemed most opposed.

I have said that the development of the one theory was scarcely influenced by that of the other. Of course, the *facts* discovered by both parties were common property, and the development of both theories depended upon the discovery of these facts; but the explanation of facts, and the reasoning from them given by each party, seemed to the other scarcely worthy of serious consideration, and were treated as matter of ridicule. And the habit of mind created by this mode of viewing the opposed theory has rendered it difficult for those who were engaged in the controversy on either side to see how nearly the two theories have now come to coincidence. Their language still remains different; but, as the facts are the same for both, it is not difficult for a neutral critic to translate from

* Presidential Address delivered before the Chemical Section of the British Association, at Belfast, August 19 1874.

the one to the other, and if we do so we shall see that there is much real ageeement between the two modes of representing chemical ideas, historically derived, the one from Berzelius, the other from Dumas, Laurent, and Gerhardt.

In both, chemical constitution is regarded as *the order in which the constituents are united in the compounds*, and the same fundamental notion is indicated in the one by reference to proximate constituents, in the other by the concatenation of atoms. To show that this is so, and that the fundamental notion can be arrived at from the dualistic, as well as from the unitary starting-point, I shall cite an illustrative case. Every student of chemical history will remember the view of the constitution of trichloracetic acid propounded by Berzelius, and afterwards supplemented by a similar view of the constitution of acetic acid, and an explanation of the likeness of some of the properties of these two substances. This has sometimes been spoken of as a subterfuge of a not very creditable kind, by means of which Berzelius apparently saved his consistency while really yielding to the arguments of his opponents. But if, instead of looking at it in the light of the substitution controversy, we consider it in itself as a contribution to speculative chemistry, we at once recognize in it a statement, in Berzelian language, of the views we now hold as to the constitution of these acids. The view was that acetic acid is a compound of oxalic acid and methyl, trichloracetic acid a compound of oxalic acid and the sesquichloride of carbon. They differ considerably from each other, because the "copulæ" (methyl and sesquichloride of carbon respectively) are different, but their resemblance is strongly marked, because they contain the same active constituent, oxalic acid, and most of the prominent characters of the substances depend upon it, and not upon the copula. Let us first free this statement from what we may call archaisms of language. It will then assume something like the following form:—The carbon in acetic acid is equally divided between two proximate constituents, one of which is an oxide, the other a hydride of carbon; trichloracetic acid similarly contains an oxide and a chloride of carbon, between which the carbon is equally divided. The oxide is the same in both acids, and is that oxide which occurs in oxalic acid. The hydride and the chloride have the composition of the substances the formulæ of which are C_2H_6 and C_2Cl_6 respectively. Oxalic acid undergoes chemical change much more readily than the corresponding hydride or chloride, and therefore the chemical character of acetic and of trichloracetic acids depends much more on the oxidized than on the other constituent, and they thus have a marked resemblance. The oxidized constituent is united to the other in a manner different from that in which oxalic acid is united to bases in the oxalates, inasmuch as, while the basic water of hydrated oxalic acid is displaced when oxalic acid unites with a base, in hydrated acetic and trichloracetic acids there is the same proportion between the basic water and the oxidized carbon as there is in oxalic acid.

Now, has not this a great resemblance to the view entertained by most modern chemists, that acetic acid is a compound of the radical carboxyl (half a molecule of oxalic acid) and the radical methyl (half a molecule of methyl gas), that trichloracetic acid similarly contains the same radical carboxyl and the radical CCl_3, and that the prominent chemical properties of these bodies depend upon their containing carboxyl, and that they therefore resemble each other?

The modern view contains nothing inconsistent with that of Berzelius, but it no doubt contains something more,—it contains an explanation of the difference between the manner in which carboxyl is united to methyl in acetic acid, and the manner in which oxalic acid is united to bases in the oxalates; but it will surely be admitted that Berzelius was here far ahead of his opponents, —so far ahead that they altogether failed to see his meaning, and looked upon his argument as a clumsy device.

The treatment by Berzelius of the constitution of the sulpho-acids furnishes a precisely similar case. These are now considered as compounds of the radical SO_2OH (which we may call sulphoxyl). This radical is half a molecule of hyposulphuric acid, Berzelius considered them as coupled compounds of hyposulphuric acid, adopting at once the view first brought forward by Kolbe, in his classical memoir on the sulphite of perchloride of carbon, and the acids derived from it.

I might pursue the history of the carbon- and sulpho-acids further, and trace the development of the theory of their constitution through the discoveries of Kolbe and his beautiful application to the cases of carbon and sulphur of Frankland's far-sighted speculations on the constitution of the organo-metallic bodies,—pointing out the relation of Kolbe's views of the constitution of acids, alcohols, aldehydes, and ketones, to the Berzelian theory on the one hand, and to the opinions of modern chemists on the other; but the greater part of such a historical sketch has been given very recently by Kolbe himself, in the *Journal für praktische Chemie*, and I may therefore omit it.

It would be easy to bring forward cases to show that our present views can be directly derived from the substitution theory and the types of Dumas and Gerhardt, through the complications of multiple and mixed types and the labyrinthine formulæ to which these gave rise, to the wonderfully simple and comprehensive system of Kekulé; but that is unnecessary, as this development has been fully and ably described by more than one thoroughly competent writer.

We have been discussing a case in which Berzelius was right in considering a compound of carbon, oxygen, and chlorine as composed of two parts—an oxide and a chloride of carbon. It is only just that we should take some notice of cases, at first sight similar, in which modern chemists would be inclined to think that he was wrong. This is the more necessary as an examination of these cases will enable us to see what was the really valuable contribution made to speculative chemistry by the substitution theory.

Compounds containing three elements were formulated in two different ways by Berzelius:—1. One of the elements was represented as combined with a radical composed of the other two,—as hydrocyanic acid, $H_2.C_2N_2$; ether, $C_4H_{10}.O$. 2. The ternary compound was represented as composed of two binary compounds having one element common,—as caustic potash, $KO.H_2O$; chromochloric acid, $2\ CrO_3.CrCl_6$.

Phosgene gas was at first formulated in the former of these ways as $CO.Cl_2$; but latterly he was forced in consistency to give up all radicals containing oxygen or other strongly electro-negative element,* and to write the formula of phosgene gas $CO_2.CCl_4$. Similarly, in every case where a positive element or radical is combined with two negative elements or radicals, he represented the compound as composed of two binary compounds. Thus —chloride or acetyl, $2\ C_4H_6O_3.C_4H_6Cl_6$, as a compound of acetic acid and the corresponding terchloride.

This was in perfect consistency with the mode in which ternary compounds containing one negative and two positive elements or radicals were formulated,—as caustic potash, $KO.H_2O$; sulphate of copper, $CuO.SO_3$, etc., but it lacks the practical justification which can be given, for the formula $C_2H_6.C_2O_3$ for acetic acid. For phosgene acts readily on water, forming carbonic and hydrochloric acids, an action which does not take place with perchloride of carbon, and it is not easy to see why the latter substance should be more readily attacked by water when combined with carbonic acid than when free. This difference did not escape the attention of Berzelius, and led him to distinguish two modes of chemical union:—

* In 1838 Berzelius was inclined to regard C_2O_2, to which he gave the name "oxatyl," as the radical of oxalic acid and oxamide.

1. Where the constituents were held together by the electro-chemical force, and wholly or partially neutralized each other, as in the oxygen and sulphur salts; and 2. Where a so-called "copula" was attached by an unknown force to a substance without greatly modifying its chemical activity. The distinction seems arbitrary; but it was not, as is usually supposed, a mere artificial bulwark to protect the electro-chemical theory; it has a real and very important meaning—a meaning which the development of the substitution theory enables us to explain.

The phenomena of electrolysis, upon which the Berzelian system is based, bring forward into great prominence *one* of the chemical units, viz., the *equivalent*, and the pre-eminent position of oxygen as the most electro-negative element made it most natural to select the atom of oxygen as the standard of equivalence, so that an equivalent of any element or radical was defined as that quantity of it which was equivalent to one atom of oxygen. Gay Lussac's law of gaseous volumes, which was adopted by Berzelius, and which, by a curious accident, happens to be true for all elements gaseous at ordinary temperatures, led to the formulæ H_2 and Cl_2 for the equivalents of hydrogen and chlorine; but although these formulæ explicitly indicate the divisibility of the equivalents of these elements this divisibility was not recognized, and integral numbers of equivalents were alone tolerated. Thus hydrochloric acid was written H_2Cl_2, ammonia N_2H_6, etc., and the etymological meaning of the word "atom" was soon lost. The use of barred letters, to indicate two atoms, or one equivalent of such elements as hydrogen and chlorine, further contributed to hide the important fact of their divisibility.

The first great result of the substitution theory was to change the unit of equivalence, and to take as the standard the atom of hydrogen or of chlorine, instead of that of oxygen; and although it would be most unjust to forget the services of Dumas, Gerhardt, and Laurent, in this matter, the credit of removing the bars from H, Cl, and their comrades, and allowing the hitherto chained partners to walk at liberty, undoubtedly belongs mainly to our distinguished colleague and master, Professor Williamson.

The establishment of the water-type, or, to put it in another form, the proof that the atom of oxygen contains two units of oxygen, inseparably united but capable of separate action, led the way to the explanation of all the difficulties which beset the theory of radicals and copulæ. It at once explained how two oxides or two sulphides unite together,* and the idea of "polybasic," or as we should now say, polyad, atoms and radicals was soon used to explain the existence of polybasic acids, double salts, acichlorides, and many other kinds of ternary compounds.

But a fact does not cease to exist because it is explained. Quick-lime and water unite together, although we can now explain how they do so, and a useful purpose may still be served by the enumeration, as in the old dualistic formulæ, of the pairs of united equivalents. Although some of these equivalents belong to the same atoms, it is nevertheless true that they are united in pairs. Caustic potash might, then, be formulated $KO\frac{1}{2}, HO\frac{1}{2}$, or, $\frac{1}{2}(K_2O,H_2O)$; phosgene gas, $\frac{1}{2}(CO_2,CCl_4)$; and chlorochromic acid, $\frac{1}{3}(2CrO_3,CrCl_6)$. These formulæ are not so well suited for general use as those now current, but the consideration of them as accurate representations of facts may enable us to see that the copulæ of Berzelius had a real and valuable meaning. Take, for instance, the formula of acetic acid—

$$H_3C-CO-OH,$$

or $\frac{3}{4}CH_4,\frac{3}{4}CO_2,\frac{1}{2}H_2O,\frac{1}{4}C_2$. It is this last term which indicates the coupled character of the compound. If we look upon acetic acid as a compound of carbon, it is a coupled compound, because all the equivalents of carbon in it do not belong to the same atom, and the two atoms of carbon are directly united together, and replacement of the equivalents united to one of these atoms does not very greatly affect the function or chemical character of the equivalents united to the other.

I have, perhaps, spent too much of your time upon these historical questions. Let us now shortly consider what is the present state of our knowledge as to chemical constitution. This I have already defined as the order in which the constituents are united in the compound. We may indeed use metaphorical language, and speak of the relative position of atoms, perhaps deluding ourselves into the notion that such language is more than metaphorical, but the phenomena of combination and decomposition, although we cannot doubt that they depend solely upon the relative position and dynamical relations of the atoms, are not alone sufficient to prove even that atoms exist. Our knowledge of the intimate structure of matter comes from another source, from the study of the properties, rather than of the changes of substances, and of the transformations of energy which accompany the transformations of matter. This is strictly a branch of chemistry: the aim of chemistry is to connect the properties of substances and the changes they undergo with their composition, taking this word in its widest sense; and we must not allow our friends in Section A to cut our science in two, and appropriate the half of it. We all frankly admit that chemistry is a branch of physics, but it is so as a whole—no section of it is more purely physical than all the rest. To accept a narrower definition of chemistry is to reduce ourselves to the position which the collector occupies among naturalists; it is to admit that it is our business to provide part of the materials out of which a science in which we have no share may be constructed by others. But we need not fear that this so-called physical side of chemistry will ever be divorced from the study of chemical change. The names of Faraday and Graham among those who have left us, of Andrews among those who are still at work, are sufficient proof of this, and a study of their researches will conclusively show that great results can be looked for in this direction only from a physicist who is also a chemist.

There are three special directions in which such investigations have already influenced chemical theory:—

1. *Electrolysis*, which has confirmed the equivalent as a chemical unit, has proved that equivalents unite in pairs—thus forming the basis of the electro-chemical theory, and has shown us how to estimate the amount of energy involved in the union of a given pair of equivalents.

2. *Vapour Density*, from which Avogadro inferred the law of molecular volumes (since proved by Clerk Maxwell), which has given us the molecule as a chemical unit, and formed the basis of the unitary theory.

3. *Specific Heat*, from which Dulong and Petit inferred their empirical law, which gives us the most satisfactory physical definition of the atom as a chemical unit.

We naturally turn to the future, and try to guess whence the next great revolution will come. For although periods of quiet have their use, as affording time for filling up the blank schedules furnished by the last speculative change, such periods have seldom been long, and each has been shorter than its predecessor.

But it is impossible to make a certain forecast. Looking back, we see a logical sequence in the history of chemical speculation, and no doubt the next step will appear, after it has been taken, to follow as naturally from the present position. One thing we can distinctly see—we are struggling towards a theory of Chemistry. Such a theory we do not possess. What we are sometimes pleased to dignify with that name is a collection of generalizations of various degrees of imperfection. We cannot attain to a real theory of chemistry until we are able to connect the science by some hypothesis with the general theory of dynamics. No attempt of this kind has hitherto been made, and it is difficult to see how any such attempt can be made until we know something in reference to the absolute size, mass, and shape of molecules and of atoms.

* It does not explain the existence of double chlorides, bromides, etc. These compounds, apparently so similar to the double oxides and sulphides, are still unexplained.

the position of the atoms in the molecule, and the nature of the forces acting upon them. Whence can we look for such knowledge?

The phenomena of gaseous diffusion, of gaseous friction, and of the propagation of heat through gases, have already given us an approximation to the size and mass of the molecules of gases. It is not unreasonable to suppose that a comparative study of the specific heat of gases and vapours may lead to some approximate knowledge as to the shapes of their molecules, and a comparison of such approximate results, with the chemical constitution of the substances, may lead to a hypothesis which will lay the foundation of a real theory of chemistry.

Chemistry will then become a branch of applied mathematics, but it will not cease to be an experimental science. Mathematics may enable us retrospectively to justify results obtained by experiment, may point out useful lines of research, and even sometimes predict entirely novel discoveries, but will not revolutionize our laboratories; mathematical will not replace chemical analysis.

We do not know when the change will take place, or whether it will be gradual or sudden, but no one who believes in the progress of human knowledge, and in the consistency of Nature, can doubt that ultimately the theory of chemistry, and of all other physical sciences, will be absorbed into the one theory of dynamics.

THE CARBIDES OF HYDROGEN PRODUCED BY THE ACTION OF ACIDS UPON CAST-IRON OR STEEL.

In the course of a recent discussion in the French Academy* on the phenomena occurring during the conversion of iron into steel, M. Dumas remarked that some experiments of M. Cloez would appear to indicate to chemists the most natural process for the accomplishment of organic syntheses. In fact, when a metal is combined with a non-metallic body, and the compound is subjected to the action of a hydrogenated or aqueous acid, the metal seizes the negative element of the acid or the oxygen of the water, whilst the non-metallic body and the hydrogen unite conformably to the proportions set free. Thus, if a sulphide or a polysulphide be acted upon, in the first case sulphuretted hydrogen, and in the second a hydride of sulphur, is produced.

According, therefore, to the nature of the hydrogenated compound formed, the metallic combination from which it is derived can, with some degree of probability, be characterized. As the compounds of which M. Cloez has recognized the formation, belong to the series designated by the formula C_nH_n, it may be concluded that they are derived from a carbide of iron, FeC, which under the influence of water and an acid produces $FeO + CH$, the latter condensing more or less, and thus yielding various polymers of the series C_nH_n.

It would seem natural, consequently, to consider white cast-iron and tempered steel as iron holding in solution more or less of this carbide, FeC. The grey cast-iron and untempered steel would contain less of this carbide than their respective analogues, and present the greater part of their carbon in the free state under the form of graphite.

The question arises whether other carbides of hydrogen are formed than those of the series C_nH_n, when steel or cast-iron is dissolved by an aqueous acid.

The affirmative would lead to the conclusion that several carbides of iron are in solution in cast-iron and steel. However this may be, the formation of one or of many definite carbides of hydrogen by the action of aqueous acids upon steel or cast-iron, connects that reaction with those which are observed when those acids are brought into contact with the ordinary binary compounds, sulphides for example.

The simple contact of carbon and hydrogen in the nascent state under such circumstances, being thus sufficient to produce definite organic compounds, from which may be derived, by known processes of transformation, all the definite combinations of organic nature, M. Dumas considers that we are more than ever justified in uniting the chemistry of organic compounds with mineral chemistry, properly so called.

JAPANESE VEGETABLE WAX.

The *Japanese Mail* contains an account of the manner in which this article of commerce is obtained. The trees from which wax is made are the *urushi*, or lacquer tree, the *yama-urushi*, the *hage-urushi*, better known as the *ronoki*, and the *koganoki.* The wax is made from the rind of the fruit. In places where the wax is manufactured to any great extent, the *urushi* is not availed of for its lacquer. As the trees are not cut for several years, they may be seen in the wax-producing districts growing to a height of 35 or 40 feet. In districts where the trees are used for their lacquer or varnish, they are cut every seven or ten years. The mode of obtaining the wax from the *urushi*, or lacquer tree, is as follows:—

Late in the autumn the branches, heavy with fruit, are lopped off and taken into the house. The fruit is pounded with a pestle, and then shaken in a basket-sieve, so as to separate seed from rind. From this rind the wax is made. The mode of expressing it differs here and there, but in no very important particulars. The following brief description is taken from the mode as followed out in Sendai and Aidzu: Boiling water is got ready in an iron cauldron, over which a lattice-work of sticks is placed, and on these some matting. The sifted rinds of the fruit are then laid out on the matting and steamed, after which they are placed in hempen bags and again steamed. The bag, with its contents, is then put in a wooden trough, wedges or blocks are inserted in the trough, and driven home into the bag with heavy blows from a mallet. An aperture at the bottom of the trough provides for the egress of the wax. The trough and wedges are made of *kiaki* wood, and the mallets and blocks of wild mulberry—a very hard wood, and well suited for the purpose. A small quantity of oil, in the proportion of about one-tenth, is added to the wax, to allow of its being expressed more easily. It then goes through another steaming process, and is again pounded in the trough.

Wax from the *yama urushi*, or wild lacquer tree, is obtained thus:—The fruit is collected at the latter end of summer, and is at once steamed, without being pounded with a pestle, as is the case with the *urushi* wax. The wax is purified by melting. A large tub of cold water is taken and placed under a wooden tank having a small aperture close to the bottom. The melted wax is then poured into this tank, and escapes through the aperture into the tub beneath; while doing so it is stirred rapidly with the hand, after which it is placed either in matting or shallow boxes, and dried in the open air for about fifteen days.

The *hage-urushi*, from which wax is largely obtained, grows in the south-western part of Japan. This tree was first brought from the Loochoo Island to Sakurajima, an island near Satsuma. Its production has so increased that there are now no less than seven different species. The *hage-urushi* tree is raised from seed or from slips. *Koga* wax is made from the fruit of the *koga* tree, which differs from the *urushi* and *hage-urushi* trees. It is an evergreen, and is largely grown in Ossugori, in the northern part of Nagato. It flowers in the middle of summer, the fruit ripening in autumn, when it is plucked and soaked in water for four or five days, after which it is trodden out with the feet, thus separating the outer rind. The *koga* wax contains a large proportion of natural oil, which in a measure restricts its use to cold and temperate districts. Candles made of it show a very bright light, and if some contrivance could be hit upon for extracting the oil, the consumption of this wax would be increased, as it is very cheap, compared with the other kinds. Refuse wax is used for manuring purposes.—*Journ. Soc. Arts.*

The Pharmaceutical Journal.

SATURDAY, AUGUST 29, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

"ADVICE" BY CHEMISTS.

THE address of the President of the Pharmaceutical Conference this year will probably attract more than ordinary consideration, since it dealt almost entirely with subjects of a political nature. Although this is holiday season now with so many, and even the papers of the metropolis show signs of dulness, there have already been some indications that the opinions and statements put forward in the address have been criticized.

The first instance of the kind was in the *British Medical Journal*, where objection was taken to a remark in reference to co-operative drug stores, to the effect that advice could not be got from the stores. Our contemporary, with somewhat of an excess of zeal for the protection of his professional brethren, forthwith runs away with the notion that this "advice" signified "counter practice," lamenting that in an address to a pharmaceutical meeting such a thing should be mentioned as a special privilege enjoyed by druggists over co-operative drug salesmen, and not as a thing to be sternly repudiated and repressed.

Now, although the use of the word "advice" may have been unfortunate, no person who is accustomed to the routine of a chemist and druggist's business in a provincial town would have been likely to have construed it in the sense adopted by our contemporary. It was therefore without surprise that we read in the next issue of our contemporary a letter from Mr. GROVES, expressing his regret that his remarks had been susceptible of such a misunderstanding, and explaining the sense in which he used the word "advice."

The "advice" that is solicited from a chemist nd druggist, as Mr. GROVES points out, ranges through a great variety of subjects. A person will bring to a chemist and druggist a bundle of prescriptions, and, on the plea that his medical adviser is not accessible, ask him to select one written for a special purpose, or perhaps to point out how the dose should be altered for differences of age or circumstances. Another person inquires respecting disinfectants for the house, or deodorants for the drains, or it may be wishes to discuss the quality of the water supply or even some abnormal appearance in his secretions. These are some of the illustrations quoted by Mr. GROVES, which will be familiar to most of our readers. Therefore, when he is able to say from experience, "I might repeat fifty such queries that have been addressed to me, the customer eventually sailing away under cover of some trifling purchase and getting his more expensive materials at the store," it is evident he may fairly claim that he was justified in saying also that chemists are particularly liable to be injured by "gratuitous brain-sucking," and in cautioning his brethren accordingly.

Of course to expect that the time will ever come when the race of seekers for "advice gratis" will be extinct would be a Utopian idea, and none probably are more painfully convinced of this than the medical profession. Questions are and will continue to be put to the chemist and druggist, and a considerable amount of tact and ingenuity is continually required to enable him, while giving information on subjects within his domain, also to shelve a tabooed subject without giving offence to the customer.

We are glad, therefore, that our contemporary considers Mr. GROVES'S letter to be "a satisfactory reply" to the strictures drawn forth by the passage in his Presidential Address. We entirely sympathize with our contemporary in its aim, and heartily desire to see the cessation of the so-called "counter prescribing" of the chemist and druggist, as well as of the no less reprehensible custom of medical men keeping open shops for the retailing of drugs and chemicals.

INSECT-DEVOURING PLANTS.

IN two of our recent numbers (PHARM. JOURN., vol. iv., pp. 999 and 1035) we gave a summary of the facts at present known with respect to the anomalous power possessed by certain plants of catching and digesting insects by means of a viscid secretion from their leaves, the most striking instances being presented by the genera *Sarracenia* and *Drosera*. A most interesting and important addition to our knowledge of this subject has just been made by Mr. DARWIN, in a communication to the Scientific Committee of the Royal Horticultural Society. He has discovered that a similar property is possessed by the leaves of the common butterwort, *Pinguicula vulgaris*. In this bog-plant—as in *Drosera*—albumen, fibrin, meat, and cartilage, induce a secretion from the glands of the upper surface of the leaf, which is feebly acid, though not so decidedly as in the case of *Drosera*. This secretion is again absorbed, and causes an aggregation of the protoplasm in the cells of the glands, such as had been observed in other similar cases. When an insect or seed is placed near the leaf, or a number of them near its margin, either the nearest point of the leaf to the seed or insect, or the whole margin as the case may be, becomes curled considerably over in the course of two or three hours; but the apex of the leaf does not turn over towards the base. Small fragments of glass cause a similar movement, though to a less extent. The inflexed point or margin pours forth a secretion which envelopes the insects or seeds, but the pieces of glass caused very little, if any, increase of the secretion. It is difficult, however, to understand the use of this inflexion; since, in the course of less than twenty-four hours, the margin of the leaf turns back again to its original position, whether the substances which appear to supply it with food be removed or not. Every one interested in the physiology of vegetation will look with the greatest eagerness for the new work promised by Mr. Darwin, in which all these remarkable phenomena will be described, and their purpose discussed. It is not impossible that some new and unexpected light may be thrown on the mode in which plants obtain their food.

The subject was also last week brought before the Biological Section of the British Association in a most interesting address by Dr. Hooker, which formed one of the principal events of the recent meeting.

THE REBUILDING OF THE PARIS SCHOOL OF PHARMACY.

Notwithstanding the promise on behalf of the French Government that provision should be made for the expense of rebuilding the Paris School of Pharmacy, the budget did not contain any allusion to it. When that portion of the budget which related to education was under discussion, M. Bert challenged the Minister on the subject; he was met with much sympathy and a shifting of the responsibility upon the Minister of Public Works. That individual, however, escaped questioning through the necessity for the rapid discussion of the budget when the estimates for his department were reached. If M. Bert's statements, however, may be taken literally, the necessity of the case may soon be enforced by the fall of the building.

We notice that in another medical journal—written, we presume, by students for students—exception is taken in high-flown and exaggerated terms to the "chemistry of disease" being included in the scientific work of the pharmacist. Perhaps when the writer's studies have been further extended he will be able to appreciate the fact that some of the most important and valuable work in this department of research has been performed by pharmacists.

Dr. J.-Léon Soubeiran, Assistant-Professor in the Paris School of Pharmacy, Honorary Member of the Pharmaceutical Society of Great Britain, to whose courtesy these pages have frequently been indebted, has recently been nominated Professor of Pharmacy in the École Supérieure at Montpellier.

Mademoiselle Andréine Doumergue, having passed the necessary examinations, has recently been admitted as a pharmacienne at Montpellier.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of the above Association was held at the rooms, Halford Street, on Tuesday, August 4th; Mr. Wright, President, in the chair.

The Committee in submitting their report of the proceedings of the Society for the half-year, congratulated the members upon the fact, that during the past session the number of persons who have joined the Society has been greater than in any previous one. The Committee, however, expressed their regret that the attendance has been below the average. This they consider has been due, partly to the attractions consequent upon the season, and more especially to the almost general opinion that a student can obtain sufficient knowledge to enable him to pass the examinations by a very short course of study in London. The Committee are firmly persuaded that this plan is quite inadequate to attain the end in view, and that this has been shown by the recent large per-centage of failures in the examinations. They wished to impress upon the members the necessity of systematic study previous to presenting themselves before the Board of Examiners. The library, which now contains the text-books necessary for students, and many of the leading works in connection with the trade, has met with an increased circulation. The laboratory is in constant use, and fully justifies the outlay expended on it. The materia medica and chemical cabinet is now nearly complete. The Committee congratulated the Society upon the possession of such a well-selected and extensive museum. One member has passed the Major, three the Minor and Modified, and two the Preliminary Examinations, during the past session. The total number of members has been forty-one. The Treasurer's report showed an income during the half-year of £7 11*s.* 4*d.*, and an expenditure of £14 6*s.* 4*d.*, leaving a balance in hand of £1 14*s.* 3*d.* The report was unanimously adopted.

A ballot was then taken for the new Committee, and the officers were elected as follows:—Mr. W. B. Clark, President; Mr. T. Wright, Vice-President; Mr. J. A. Basker, Treasurer; Mr. A. W. Shakespeare, Hon. Secretary; Mr. E. H. Butler, Mr. S. H. Cadoux, Mr. E. J. Bishop.

A programme of lectures, classes, etc., extending to February 2, 1875, has been issued.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE

(*Continued from page* 146.)

Report on the Chemistry of the Aconitines.

I. Preparation of the Alkaloids.

BY T. B. GROVES.

The sum of £10, voted for the above purpose and derived from the Hill's fund, was intended to be expended mainly on the preparation of sufficient crystalline nitrate of aconitine, to justify Dr. C. R. A. Wright in undertaking an exhaustive inquiry as to its true chemical constitution. Enough of the pseudaconitine had already been prepared by me and exhibited at the Bradford meeting of this Conference.

Messrs. Hopkins and Williams having kindly offered to perform the preliminary operations, one cwt. of a fine sample of roots of *Aconitum Napellus* was purchased and entrusted to them for that purpose.

On February 20th, I received from them the acid washings of the crude ethereal solution of the whole alkaloidal matters of the roots soluble in that menstruum. The process adopted was a modification of that of Stas.

The bulk of this fluid having been reduced from one gallon to 1½ pints, it was digested with animal charcoal, alkalized with ammonia, and thoroughly washed with ether. The ethereal solution so obtained, shaken with half a fluid-ounce of nitric acid diluted with eight ounces of water, gave an aqueous solution of the alkaloids of acid reaction, which was allowed to evaporate spontaneously to a thin syrup. It showing no disposition to crystallize, a few crystals of nitrate of aconitine, reserved from the sample I made several years before, were sprinkled on its surface. Crystallization soon commenced, and was allowed to proceed until the mother-liquor became densely syrupy. A second crop was obtained, but the whole not amounting in the crude state to one ounce, it was thought advisable to commence operations on a second cwt. of roots. No sooner was the order given than Messrs. Hopkin and Williams set to work with most praiseworthy promptitude, and I found that when I wrote in haste, two days afterwards, to countermand the order, I was too late. The reason of my doing so was this—my residual mother-liquor had suddenly thrown down a mass of crystals that made what was previously liquid semi-solid.

These crystals were mostly needle-shaped, and of microscopic dimensions. Under thin glass, they appeared, after a time, to undergo change of form, and assume the rhombohedral shape characteristic of the aconitines.

These crystalline cakes were now set aside to be worked up with the proceeds of the second cwt., and the mother liquors were bottled for the same purpose, a little ether being previously added as a preservative.

On February 28th, I commenced the treatment of the second batch, which arrived in the state in which it left the still, after recovery of the spirit—an acid liquid measuring two gallons, with an oleo-resinous stratum measuring three pints floating on its surface. This latter was removed and washed. Ammonia having been added to the clear liquid, it was well washed with ether, and proceeded with as previously described.

The alkaloid so obtained required five fluid drachms of nitric acid for neutralization, and when set aside began to crystallize at once. I attribute this improvement to greater expedition in treating the liquid, and the avoiding of undue dilution.

Two considerable crops of crystals were obtained, and, by moderate washing and careful application of the press, were rendered nearly white.

Before proceeding to recrystallize these cakes, it was thought advisable to purify the last cake obtained from the first cwt. These fine silky crystals had entangled so much of their mother-liquor that the cake had become superficially brown. The yield was but small, about one-third of what I expected.

The recrystallization of the whole yielded 13 drachms of presumably pure nitrate of aconitine. That it was unfortunately not so will appear hereafter.

Treatment of the Mother-Liquors.—The whole of the mother-liquors were now mixed, well diluted, and rendered slightly alkaline with ammonia, so that it could be perceived by its smell. The dark-coloured alkaloid thrown down was separated by filter and dried in air. It weighed about four drachms, and was when dry perfectly black.

The filtrate containing an abundance of alkaloids precipitable by larger doses of ammonia, was now neutralized with hydrochloric acid, and evaporated to a small bulk. When approaching the volume of 10 oz., it appeared turbid, and when allowed to cool it deposited a stratum of a transparent, syrupy substance or varnish, measuring about two ounces. This matter was soluble in water, but not in its mother-liquor, except by the aid of an excess of hydrochloric acid. On heating the solution it immediately became turbid, and re-deposited the varnish which, when the liquid cooled, was again taken into solution.

After a good deal of experiment, which I need not repeat, I found that the precipitation of the varnish was determined by the presence of muriate of ammonia in sufficient quantity to form a dense solution, in which, when hot, this hydrochlorate was insoluble.

The varnish thus obtained was, as far as possible, freed from contamination by muriate of ammonia, diluted with water, in which it dissolved, and set aside for the night. In the morning it was found to be full of well-defined, colourless crystals, which, separated from the mother-liquor, washed, pressed, and recrystallized, were obtained pure. They evidently formed the crystalline portion of the varnish, the residue being for the most part, in all probability, an amorphous modification of it. These crystals weighed between two and three drachms. They were not very soluble in cold water. Their *dilute* solution was not precipitated by either ammonia, liquor potassæ, or carbonate of potash, except on the application of heat, when the alkaloid separated as a thick coagulum, fusible in boiling water. It was precipitated by iodo-mercurate, by tannin and by acid nitrate of silver. The alkaloid was soluble in ether and chloroform. The muriate crystallized readily from hot solutions in fine needles, which were but feeble polarizers, except in the case of a few larger crystals that formed at the edge of the slide.

Their taste was purely bitter and devoid of acridity. Colour reactions with sulphuric acid, do. plus nitric acid, nitric acid, and chromic acid could not be obtained with them.

A moderately strong solution, warmed with powdered muriate of ammonia, became turbid, and the heat being continued, deposited the whole of the alkaloid in well-defined crystals. This test seems to be of some value. It answers also when applied to the nitrate.

I have no doubt that this substance constituted the greater portion of the third crop of crystals from the first cwt. of roots.

The varnish, after several solutions and precipitations, became denser and darker in colour.

The supernatant liquor on each occasion showed signs of containing alkaloid, but considerably less in the last than in the first.

They were all mixed, and a rather strong dose of ammonia being added, an alkaloid was thrown down, that when dried seemed to be possessed of very considerable acridity—at least so I judge from involuntary experiments made upon my eyes and nose.

The remaining alkaloids were washed out with ether, which, when evaporated, left a fusible transparent alkaloidal substance similar to that obtained from *Aconitum ferox* under the same circumstances, and which has been incorrectly termed Napellin.

Examination of the Nitrate of Aconitine.

It will be remembered that one of the characters of pure crystallizable aconitine was this, that when its ammoniacal solution was heated to boiling point (care must be taken that it does not actually boil), it deposits well-formed crystals of the alkaloid.

Presuming that my new product would do the same, the experiment was tried on 30 gr. The result was *nil.* Tried again on a much smaller scale, there still was no result. Examined microscopically, it was evident that there were two sorts of crystals present, one resembling true nitrate of aconitine, the other composed of radiating needles. Seen by help of polarized light, the former polarized splendidly, the latter scarcely perceptibly. Compared with the nitrate of aconitine prepared by the iodo-mercurate process, its colours were decidedly more brilliant.

There was a similar difference observable between the pseudaconitines. That made by the iodo-mercurate process crystallized in rhomboidal plates, which were fairly good polarizers. That made by Stas' process, of which I have one and a half ounces for experiment, showed few of these rhomboidal shapes. It crystallized with difficulty in groups of very long needles, that measured at least one-third of the width of the slide, and it polarized much more beautifully than its twin brother, though I afterwards observed that lapse of time seemed to make them approximate.

After consultation with Dr. Wright, it was thought advisable to attempt their purification by converting them into iodo-mercurates and regenerating the alkaloids.

This was done, in the usual way, with 100 grains of each substance. As soon as the nitrate of aconitine so obtained was set aside to crystallize, a considerable number of colourless, stout, transparent needles, arranged in stars, made their appearance and increased in number and size till the next day, when crystals of another character beginning to show themselves, they were removed and purified by recrystallization. They weighed nearly 20 grains, and proved, on examination, to be the nitrate of the unknown alkaloid of which the muriate has already been described.

Its crystals, viewed as they were obtained, showed here and there only a trace of colour, when examined by polarized light; but when a strong solution was allowed to crystallize under thin glass, both their shape and character entirely changed. They closely resembled those of aconitine, and were brilliant polarizers. Although apparently inert, they form, I have no doubt, one of the aconitine series—perhaps are the active principle found in *Aconitum heterophyllum*, by Mr. J. Broughton, the quinologist, and named by him atisine.

The roots from which my alkaloid was obtained were imported from Germany, and from inquiries kindly made by Mr. Holmes, I learn that there is no reason for suspecting that the Indian *A. heterophyllum* was mixed with it.

Aconitum heterophyllum, called in India "atees," is sold everywhere in the bazaars as a popular bitter tonic. It possesses no acridity whatever.

From experiments I have made with the uncrystallizable alkaloids of *Aconitum ferox*, I believe that this bitter alkaloid is present there also in small quantity.

The nitrate of aconitine now crystallized out in hard but small crystals, attached to the sides and bottom of the vessel. Microscopic examination, however, showed that they were not quite pure, and on trying their degree of solubility in ammonia water, it was found that, instead of 520, they required only 460 parts for solution, and again that, on heating this to boiling point, no crystals were obtainable. It was decided, therefore, not to be sufficiently pure for chemical purposes.

The regenerated pseudaconitine, when its ethereal solution was set aside, commenced to crystallize in about an hour, by depositing on the sides of the beaker brilliant rhombohedra. As the liquid became more concentrated these increased in number, but at the same time a crystalline crust crept up the sides, and had from time to time to be scraped down into the liquid. Its crystallizing tendency had, as in the case of the nitrate of aconitine, been very much improved by the process. Crystallized from spirit of wine, under thin glass, it showed no tendency to form the long needles I have mentioned as characteristic of its original condition, but, on the other hand, there were present some very suspicious tufts that evidently were not pseudaconitine. The rest of the substance crystallized very nicely and polarized splendidly. Its solubility in ammonia water was tried, and found very much less than it should be. Its employment had, therefore, also to be given up.

These processes had consumed a great deal of time, and the meeting of Conference was rapidly approaching. Feeling that it would be impossible to purify the alkaloids sufficiently for Dr. Wright's examination prior to the meeting, I determined on sacrificing my old specimens of aconitine and pseudaconitine, made originally by the iodo-mercurate process, and presumably pure. I had just sufficient for two combustions of each alkaloid.

Dr. Wright, at considerable inconvenience to himself, undertook the work, and, after a short time, sent me his results, which were, indeed, surprising.

All three alkaloids, aconitine, pseudaconitine, and the bitter alkaloid, furnish identical or very closely corresponding centesimal numbers. It would be premature to publish these numbers before Dr. Wright has had opportunities of repeating and varying his experiments, but, so far as he has gone, he has obtained good evidence that these substances, so widely differing, both chemically and physiologically, are either isomers or polymers, most probably the latter.

The researches of Dr. Wright on the polymerides of morphia and codeia reveal many examples of complete change of physiological character caused by polymerization, but I doubt whether the drop from aconitine to a substance apparently inert will ever be exceeded, equalled. Mr. Broughton has this day informed me that he is quite certain that his alkaloid does not give the same centesimal numbers as aconitine. My alkaloid in that case must be quite distinct from atisine.

Since our last meeting, Dr. T. R. Frazer has published some results on the physiological action of crystalline aconitia and pseudaconitine. He found that a very remarkable and exceptional difference of toxicity for different species of animals existed; for whilst aconitia was for frogs about five times more powerful as a toxic agent than pseudaconitine, the latter substance was for rabbits about twice as powerful as the former. It was ascertained that this difference depended on aconitia possessing a more energetic action on the heart, and a less energetic action on the respiratory movements, than pseudaconitine.

Professor Bentley: It is my pleasing duty as Vice-President to move a cordial vote of thanks to our President for the further admirable report which he has just read, for those who are familiar with the meetings of the Conference in former years know very well that this is only one of a series. I cannot of course speak as a chemist, but all who have had an opportunity of discussing this subject will agree with me as to the great accuracy and originality of those papers. We have been told to-day that it would be the work of a lifetime to investigate opium, cinchona, or digitalis, and I am sure all here will hope with me that our President may long live, and will give us many further reports of his investigations into the aconite bases.

The vote of thanks was passed unanimously.

Mr. Hanbury: I much regret that Mr. Broughton is not in the room, for I had hoped he would have been here, and have told us something about the alkaloid he has obtained from the root *Aconitum heterophyllum*,—which is called "*Atis*" in India—and which he has not yet described in print. I think the name "*Atisine*" provisionally placed on Mr. Groves's phials, is rather doubtful, inasmuch as we are not at all sure that the substance is the same as that which has been obtained by Mr. Broughton in India from the true *Atis*.

The President: I am not at all certain about the name, or that this substance is the same, but I showed some slides under the microscope to Mr. Broughton last evening, and he thought they were similar, and, from what he remembered of the chemical reactions, I have a very strong doubt whether mine is really a new thing. I certainly do not want to claim it unless it is, because it would be unpleasant to withdraw such a claim. However, it is very interesting to find that the muriate of aconitine should be so powerful a poison, while this is directly the contrary.

Mr. Hanbury: I should like to ask what evidence you have that it is inactive on animals?

The President: The evidence is that I have taken it myself in half-grain doses, and that it has had no effect whatever; it is simply bitter.

The next paper read was:—

The Official Plasters.—Improved Formulæ for their Preparation.

BY A. W. GERRARD,

Dispenser and Teacher of Pharmacy to University College Hospital.

From a knowledge of the unsatisfactory character of most of the forms given for the preparation of the official plasters, I was induced to undertake a number of experiments with a view to their improvement.

My principal reason for attempting this work is the hope that at some future day the compilers of that book with which our calling is more closely associated than any other, may deem it necessary to give these preparations their attention.

The official plasters are fourteen in number, and will be treated upon in the order of their sequence, with the exception of cantharides plaster, which I hope to make the subject of a future special communication. I may inform you that I have made a number of experiments upon this plaster, but as they are not yet concluded any remarks would be premature.

Emplastrum Ammoniaci cum Hydrargyro.—The ingredients of this plaster are ammoniacum, mercury, olive oil, and sulphur. The first part of the process for its preparation is to dissolve the sulphur in the oil. This forms what is known as balsam of sulphur, and is then used for the extinction of the mercury. When this is accomplished, it is added to the liquefied ammoniacum, and mixed well.

In the Pharmacopœia instructions, too much is left to the judgment of the manipulator, the means for the liquefaction of the ammoniacum, and the necessary provision of straining, being omitted.

Solution of the ammoniacum may be effected by heat, water, or alcohol. Water is the most economical, one pound requiring twelve ounces of water, heating in a water bath, straining through muslin, and finally evaporating to a plaster consistence. This plaster, as supplied by wholesale druggists, is sometimes so soft that when spread upon calico it cannot be rolled for fear of sticking together; at other times so hard that when rolled and unrolled it cracks into a multitude of minute fragments, which at once separate from the calico. Two causes may be ascribed for this, one the amount of evaporation the strained ammoniacum has received; the other and most important, the kind of gum resin used in its preparation.

There are two varieties of ammoniacum in the market; one in hard brittle distinct tears, the other in softish masses of agglomerated tears, containing a large amount of impurity. In my experience, the best plaster is made from the tears. I find, after evaporating the whole of the water from the softer kind, it is then too sticky to make a good plaster.

Doubling the quantities of sulphur and oil for reducing the mercury would be an advantage, as saving time. I also find the addition of some yellow wax is an improvement, rendering the plaster more pliable.

The following is the form I would recommend:—

Take of—

Ammoniacum, in tears . . .	10 ounces.
Water	8 „
Yellow Wax	2 „
Mercury	3 „
Olive Oil	4 drachms.
Sulphur	16 grains.

Heat the oil and sulphur together, stirring until they unite; with this mixture triturate the mercury until globules are no longer visible; dissolve the ammoniacum in the water by means of a steam bath, strain, and evaporate the strained product to the proper consistence for a plaster; add the wax, and, when melted, stir in the prepared mercury and mix thoroughly.

Emplastrum Belladonnæ.—This is one of the most important and best of this class of preparations, and I believe the most frequently prescribed; when correctly prepared, it is a valuable topical application. In the last London Pharmacopœia it was ordered to be made by mixing together equal parts of extract of belladonna and soap plaster—a proceeding not easy to accomplish, unless by the addition of water; on evaporating this water a large portion of the extract, probably the chlorophyll and albumen, separated to the bottom of the vessel, changed to a brown colour. Perhaps, from a knowledge of these defects, the authors of the B. P. deemed it advisable to alter the formula to the following:—

"Take of

Extract of Belladonna } Resin Plaster . . }	of each 3 ounces.
Rectified Spirit . .	6 fluid ounces.

Rub the extract and spirit together in a mortar, and when the insoluble matter has subsided, decant the clear solution, remove the spirit by distillation or evaporation, and mix the alcoholic extract thus obtained with the resin plaster, melted by the heat of a water bath."

The originator of the above no doubt intended it to be of the same strength as the P. L. plaster; if the spirit accomplished a thorough exhaustion of the active principles of the extract—which it does not by a long way—it really would be stronger, as the London Pharmacopœia extract contained the albumen, but the B. P. extract does not.

The present form was badly devised and cannot be commended, either as an economical or a pharmaceutical achievement; it was a little advance in the right direction, but still not what it might have been. Is it not waste of labour and material to prepare one extract from another, and that inefficiently, when the materials are at hand for its direct preparation?

Following are some experiments I made upon the dried root and leaf of belladonna, exhausting them with rectified and proof spirits; also upon extract of belladonna, exhausting it with rectified spirit; the object of this was to determine which yielded the best and most economical plaster.

Twenty-five drachms of dried belladonna leaf were coarsely powdered and macerated in half-a-pint of proof spirit for twenty-four hours, then transferred to a percolator, and treated with a pint of proof spirit, and displaced with water; the product was evaporated, and yielded six and a-half drachms of softish extract = to 26 per cent. This extract did not mix well with lead plaster.

Three samples of dried root, treated as above, yielded respectively 25·5, 26·3, and 28· per cent. of extract, being a mean of 26·6 per cent. This extract mixed better than the above with the lead plaster, but required a good deal of stirring to accomplish it.

The same quantities of each of the above roots and leaf were treated with rectified spirit; the leaf gave $7\frac{1}{2}$ per cent. of extract, and the aggregate yield of the root was 5 per cent.

250 grains of extract of belladonna gave, with 500 minims of rectified spirit, $42\frac{1}{2}$ grains of extract = to 18 per cent.

Most of the above results have been verified by a note to me on the subject by Mr. Umney.

The greatest yield of extracts, as would be expected, was obtained from the proof-spirit exhaustions, but, as I have before stated, they do not mix well with lead plaster, and must be passed over as unsuited for my purpose. It therefore remains to decide between the alcoholic extracts of the leaf, root, and watery extract. The last-named gives the greatest apparent result, but a little consideration of the subject will demonstrate that it is otherwise. 700 parts of fresh plant yield an average of 32 parts of official extract, and this official extract yields, with rectified spirit, 6 per cent. of extract of uncertain alcoholic strength. Now, 700 parts of fresh plant equal 100 of dried, and this yields, with rectified spirit, $7\frac{1}{2}$ per cent. true resinous extract; so that in one case, where the extract is used, the plant yields 6 per cent. of extract, of a strength somewhere between proof and rectified, and in the other, when the dried leaf is used, we obtain $7\frac{1}{2}$ per cent. It is, therefore, obvious that the dried leaf is to be preferred to the watery extract. It now remains to decide between the merits of root and leaf. Economically, the leaf is the best, it giving

7½ per cent. of resinous extract against 5 from the root, but the more important consideration is their respective therapeutic value. To decide this question, I shall quote from a paper of M. Lefort, "On the Distribution of Atropine in the Leaves and Roots of Belladonna," which was copied in the *Pharmaceutical Journal* of June the 2nd, 1872. He thus speaks on the subject :—

"Except in atropine, the composition of the leaf was far from resembling the root of the belladonna ; and this is a fact important to be remembered when it is sought to compare their physiological and therapeutic properties. In former experiments, the dried leaf was found to contain three per cent. of a fatty matter coloured by chlorophyll, giving off strongly the odour peculiar to the poisonous Solanaceæ. The dried root does not contain more than one per cent. of this matter. The nature of this poisonous principle, and the part that it plays in the preparations that contain it, is a subject worthy of investigation.

"Without doubt plants produce upon the animal economy physiological effects as much more decisive as their chemical composition is more pronounced, but it must not be forgotten that their special therapeutic properties are often as much due to the combined action of the constituent principles as to the predominance of one, so that, considering the difference existing in the composition of the belladonna leaf and the root, it is difficult to make a comparison between them as to their therapeutic action, and they should rather be looked upon as relatively than absolutely similar.

"The principal conclusions of the author as affecting this subject are (1), that in general composition the root differs notably from the leaf ; (2), that though the root is frequently richer in atropine than the leaf, the proportion is much more variable, and therefore the leaf would have more uniform therapeutic properties."

These results, with my own experiments, I consider justify me in deciding that a resinous extract of the dried leaf of belladonna is a more correct and uniform representative of the plant than the root, and therefore would be the best to use in preparing this plaster. The form I propose is the following :—

Take of—

Dried Belladonna Leaf	50 parts.
Rectified Spirit	a sufficiency.
Lead Plaster	a sufficiency.

Macerate the belladonna leaf with fifty parts of spirit for twenty-four hours, pack in a percolator, and exhaust with more spirit ; distil or evaporate the spirit until of a proper extract consistence. To every part of this extract add eleven parts of lead plaster, and dissolve by the heat of a steam bath, and mix well.

I have mentioned rectified spirit for the exhaustion of the belladonna, but this is an instance in which there can be no reasonable objection to the use of methylated spirit. I have compared the extracts prepared both ways, and cannot distinguish them.

We have a belladonna plaster in the University College Hospital Pharmacopœia, introduced by Mr. Martindale, and prepared with a resinous extract of the root, as suggested by the late Mr. Balmer, from which excellent results are obtained ; the proportions are one of extract to nine of lead plaster. This is, I think, rather too strong, as it frequently produces an unpleasant eruption upon the patient. The same effect, even to a more marked extent, has been produced from a plaster of the same strength, prepared from the leaf, so that I considered it advisable to reduce the proportions as above.

The United States Pharmacopœia orders its belladonna plaster to be prepared by exhausting one pound of root with spirit, and adding the resulting extract to make one pound with lead plaster: this does not give uniform results, the yield of extract varying from three to eight per cent.

Emplastrum Calefaciens.—This plaster was originally in some of the older editions of the London Pharmacopœia, but was omitted from the latter, probably on account of the small particles of Spanish-fly it contained causing too much irritation, it being made with powdered cantharides and Burgundy pitch. For this reason, on its introduction to the B. P., the method and materials of its preparation were wisely changed. It is now made by exhausting cantharides with boiling water, evaporating and mixing the result with expressed oil of nutmeg, yellow wax, resin, soap plaster, and resin plaster. The expressed oil of nutmeg is an elegant addition, but it and the wax together weaken the adhesiveness of the plaster. To remedy this, the soap plaster present might be substituted by resin plaster, as it is the most adhesive. I have found this an improvement. The formula would then be as follows :—

Take of—

Cantharides, in coarse powder	of each 4 ounces.
Expressed Oil of Nutmeg .	
Yellow Wax	
Resin	
Resin Plaster	5¼ pounds.
Boiling Water	1 pint.

It is matter for regret that no better means have yet been adopted for the exhaustion of cantharides in the preparation of plasters than the wasteful processes at our disposal. Acetic ether would be an improvement upon anything in present use, and probably for this purpose it is now official.

Emplastrum Cerati Saponis.—This plaster is made by boiling together vinegar and oxide of lead until they have combined, then add soap, and boil again until most of the moisture has evaporated ; finally add wax and olive oil melted together, stir well and continue the heat until, by the evaporation of the remaining moisture, the product is of the proper consistence for a plaster.

This was originally in the L. P. as soap cerate, and was first classed among the plasters in the B. P. 1864, to which preparations it more correctly belongs. It is a curious combination of ingredients involving several chemical changes for its preparation. In the first place boiling the vinegar and oxide of lead together yields subacetate of lead ; to this is added the hard soap or oleate of soda, which decomposes a portion of the lead salt, forming oleate of lead, and acetate of soda, then is added olive oil and wax, the olive oil decomposing another portion of subacetate of lead, forming oleate of lead, glycerine, and free acetic acid.

This plaster contains a larger proportion of lead than any other in the Pharmacopœia, and essentially consists of oleate and acetate of lead. The method I adopt for its preparation differs from the B. P., in that I use eighteen ounces of acetic acid instead of the gallon of vinegar. Practically I find this the correct quantity to dissolve the oxide of lead; it also yields a more uniform plaster, and saves about two hours in the process.

The spread plaster of this preparation is a great favourite with some surgeons, and, when spread upon a special material, is the principal ingredient of what is known as dreadnought plaster.

Emplastrum Ferri is prepared by mixing hydrated peroxide of iron with melted Burgundy pitch and lead plaster. This is used as a strengthening plaster, but its value may more correctly be attributed to the protection and mechanical support it affords, than to any tonic effect of the iron.

Prepared as above, and spread during the hot weather, it takes some days to dry, the surface loses its gloss, and is covered with a greyish film. I find the omission of the Burgundy pitch obviates this, and improves the plaster.

If a good coloured plaster is desired, a dark coloured oxide of iron must be used. That which has been subjected to a strong heat is the best, and pale coloured oxides may be thus changed ; it should be passed through a fine sieve before mixing with the other ingredients.

Some plaster makers have used the resin of dragon's blood for improving its colour; this practice is now, I believe, abandoned.

Emplastrum Galbani.—This is seldom used, and samples I have prepared of it are satisfactory; all I have to suggest is that the same instructions be given for dissolving the gum resins as I have pointed out for ammoniacum and mercury plaster.

Emplastrum Hydrargyri.—In this plaster the proportions of olive oil and sulphur might be doubled with advantage; otherwise it is satisfactory.

Emplastrum Opii.—Prepared by mixing one part of opium in fine powder with nine parts of resin plaster. The above is the form of the last Dublin Pharmacopœia; in the L.P. it was made from extract of opium, lead plaster, and frankincense. The substitution of resin plaster for lead plaster and frankincense is an improvement, but I should have preferred the continuation of extract of opium. The powder of opium, on mixing with the resin plaster, has a tendency to agglomerate into particles which are difficult to separate, and when spreading, it cannot be kept equally diffused through the plaster; the particles are also likely to irritate. The mixing of a watery extract of opium with resin plaster is, however, not to be accomplished unless some intervening agency be employed, and I find glycerine to answer the purpose; each ounce of extract requires half an ounce each of glycerine and water. When thus prepared, it mixes readily with the resin plaster, and yields a smooth, uniform, and comparatively elegant preparation.

Calculating opium to yield half its weight of extract, the form would stand thus:—

Take of—

Extract of Opium	1 ounce.
Glycerine, Water } of each	$\frac{1}{2}$ "
Resin Plaster	18 ounces.

Dissolve the extract in the glycerine and water by a gentle heat, mix this with a small portion of melted resin plaster, gradually add the remainder, and stir well.

I have no doubt that a resinous extract of opium would be most compatible with resin plaster, but, in choosing the watery extract, I have borne in mind that it more nearly represents the combined constituents of opium than the former.

Emplastrum Picis.—Pitch plaster is seldom or never used as a strapping, but generally spread upon leather for local application. The water in the present form serves no purpose, so that it might be omitted.

Emplastrum Plumbi.—This is the most extensively used plaster of the Pharmacopœia, forming the principal basis of nine of the fourteen. It is prepared from oxide of lead, olive oil, and water. On mixing these ingredients and applying the necessary heat, the fatty acids, assisted by the steam generated from the water, decompose the oxide of lead with the formation of oleate of lead, glycerine is set free and partly carried off by the steam. If the whole of the water be evaporated, the plaster becomes opaque, assuming a velvety appearance; the source of heat should then be removed. as when it arrives at this point it is in the best condition for spreading.

In the London, Dublin, and Edinburgh Pharmacopœias, the proportions of its ingredients were very approximate; the United States Pharmacopœia orders one-fifth more oxide of lead. In the first B.P., the proportions were altered by reducing the oxide of lead about one-fifth. The reason for this is said to be its previous deficiency in adhesiveness. It certainly was hard and brittle, and required some alteration, but as it now stands it errs in the opposite direction, by being too soft and sticky. I will allow that the present plaster can be made harder by adding more water and continued boiling, but this is at the cost of labour, time and fuel, which the addition of a little more oxide of lead would economize, and yield a superior product.

From a large number of experiments I have decided that the following proportions give the best plaster, and, in deciding upon these, I have borne in mind that its principal requirements are adhesiveness and flexibility:—

Take of—

Oxide of Lead, in fine powder . .	6 pounds.
Olive Oil	10 pints.
Water	4 "

Boil these ingredients together gently by the heat of a steam bath, stirring constantly until they unite and acquire the proper consistence for a plaster; more water may be added during the process if necessary.

The B. P. instructions are to simmer four or five hours, made as above, in a proper steam pan; one hundredweight can be completed in an hour and a half.

Good fresh Italian oil only should be used, as it produces a superior and more pliable plaster than any other kind.

A very good lead plaster can be made from nut oil, which I believe is used by some makers; a sample I prepared from it appeared equally as good as that made from olive oil. As to its adhesive and keeping properties I have no experience, but believe, considering nut oil is less prone to rancidity than olive oil, it would be found quite equal, if not superior, in these respects.

Emplastrum Plumbi Iodidi.—The form for this plaster is the worst in the series, and reflects no credit upon its author; had it been submitted to a practical pharmacist for preparation before it was made official, it never would have disgraced the Pharmacopœia.

Though made with iodide of lead, it contains scarcely any, it being nearly all decomposed by the soap present in the soap and resin plasters with which it is mixed; the fatty acid of the soap combining with the lead to form lead plaster, and the soda of the soap with the iodine to form iodide and iodate of soda. The resulting plaster, instead of being bright yellow, is of a whitey-brown colour.

To improve this formula, all that is necessary is to omit the soap and prepare as follows:—

Take of—

Iodide of Lead, in fine powder . .	2 ounces.
Resin	$1\frac{1}{2}$ "
Lead Plaster	1 pound.

Melt the resin and lead plaster, then stir in the iodide of lead.

Emplastrum Resinæ.—This is the best and most adhesive strapping plaster in the Pharmacopœia, forming, when spread upon good stout linen or calico, an excellent preparation for the surgeon's use.

The B. P. proportions do not give a good plaster all the year round; spread during the cold winter weather it is satisfactory, but in the hot summer weather it is so sticky that it cannot be rolled without spoiling. To overcome this difficulty it is necessary that the plaster spreader should use his judgment in apportioning the resin according to the season of the year. My experience in this matter—and I have spread some thousands of yards of the plaster—is to use the B. P. form in winter, in the spring use half, in the summer and autumn one-fourth the quantities of soap and resin ordered in the official form. I have always found this give the greatest satisfaction.

Next to a good plaster, the material upon which it is spread is of importance. A stout linen sheeting that has been partly worn so as to deprive it of its stiffness and dress, is from long experience found to be the very best material for the surgeon's and operator's use. From its pliability it has the property of adapting itself to the irregularities of a limb without the formation of folds or creases to irritate and annoy the patient.

Mr. T. Bryant in his work on "Surgery," in speaking of the value of a good strapping for the treatment of indolent ulcers, says, "It should be spread upon good stout linen instead of the sleazy material usually sold." Next to linen a very good material is calico of a kind called the Croydon finish. This is very good and cheap, but is not quite so strong and adhesive as the linen.

A very good plaster for ordinary use may also be spread upon what is called pillow calico. This has a linen finish, and would be scarcely known from linen.

Emplastrum Saponis.—This plaster is generally used for the same purposes as the foregoing. It differs from it in containing more soap and less resin, and is therefore less adhesive. Its special uses as compared to resin plaster I am not acquainted with, and as far as my experience extends, there seems no necessity for alteration.

Now that I have finished my review, before I leave you I feel desirous of introducing to your notice the existing apparatus (so far as my knowledge extends) used for plaster-spreading. Here is a machine invented by Mr. Martindale. I will not enter into a minute description of its parts, but for the information of those who require it, they will find it in the *Pharmaceutical Journal*, vol. ii., page 33. To any one who understands the principles of its construction, with a little practice they may soon learn to spread plasters, but let them not attempt it unless they make up their minds to spoil the first 50 yards.

Here is another machine for making what I define as hand-spread plasters. It is composed of two trestles, the top rails, which are eighteen inches wide, being studded with tenter hooks at intervals of 1¼ inches. These trestles are placed at a distance apart equal to the length of plaster to be spread; the ends of the linen or calico are then fixed on the tenter hooks and strained tight by pulling a trestle ; a portion of melted plaster is then poured upon the linen at one end, and drawn along its surface by the edge of a thick spatula ; this operation is repeated a second and third time, when the plaster may be trimmed and removed from its frame. That is a pharmaceutical operation which, perhaps, you have never before witnessed; it has, however, been practised in a large metropolitan hospital, viz., Guy's, for upwards of a century, and is still in use. This method of spreading requires even more practice and certainly more skill and dexterity than the former ; it nevertheless might be found useful to some, as the cost of the apparatus is trifling.

Besides what I have shown and told you, there is a large amount of technical knowledge required for the successful practice of plaster-making and spreading. This is only to be acquired by frequent practice, such as the general pharmacist cannot be expected to obtain. For these reasons this branch of pharmacy must remain to a large extent a speciality.

There is one more subject I desire to touch upon. It is that of shaped marginal plasters upon leather. Most of us know how well those of some makers are spread, but how this is accomplished we, or at least I am at present in the dark.

I have often thought what a great convenience it would be in a pharmacy if, instead of the unsatisfactory plaster spatula we now use, some cheap and simple apparatus could be devised for spreading shaped plasters in a neat and workmanlike manner. I therefore suggest that the Executive of our Conference could not better dispose of any surplus funds than by offering a portion as a premium for such an invention.

In conclusion, the results I have arrived at, and the suggestions I have made with reference to plasters, were obtained in each case from several experiments, varying the proportions of material. I do not wish to force upon you that they yield the very best results, for I am but a novice, and know that my experience in the subject is limited as compared with others. There may be those here to-day who have something to contribute to what I have stated, or whose experience differs with mine. If these expressions succeed in withdrawing their knowledge from its solitude and conservation, it will be the means of lending a helping hand to the progress of pharmacy.

The PRESIDENT: We are highly indebted to Mr. Gerrard for the very conscientious way in which he has worked out his subject, and I am sure Mr. Hills would be greatly pleased, were he here, to see what the result of spending his money has been. To properly discuss this question would take a long time, but I think it would be better, if we attempt to do anything of the sort, to do it methodically, and to take each plaster separately; but I will first ask you to pass Mr. Gerrard a vote of thanks.

The vote of thanks was passed unanimously.

The PRESIDENT : The Emplastrum belladonnæ will probably offer more scope for discussion than the first one on the list. The great objection to the present emplastrum is its messiness; it is such a dark green colour that if it at all flows beyond the margin of the leather, it soils the clothes of the patient. I should have been glad to have heard that the root could be properly used instead of the leaf, so as to avoid the green colour produced by the chlorophyll, though I do not much believe in any plaster myself, except the Emplastrum cantharides.

Mr. MARTINDALE : I have had a little experience in making this plaster according to the formula which I introduced into the University College Hospital, altered from that of the B. P., on account of the disadvantages Mr. Gerrard has pointed out. Making an extract of an extract is a very wasteful mode of making a plaster. I took the Hospital formula from Mr. Balmer, who published a paper in the *Pharmaceutical Journal* some years ago for making it with an extract prepared from the root of the belladonna. Remembering the good effects of the liniment so made introduced by Mr. Squire, Mr. Balmer thought this would be a better preparation than anything made from the leaf or from the crude extract. He, himself, told me that he had derived great relief from the application of such plasters. I accordingly adopted it, and I used the strength he gave for some time at the University College Hospital, I think it was one part of the alcoholic extract of the root to two or three of lead plaster ; but it was complained of, that it produced an eruption almost similar to that of scarlet fever. The physiological action it produced—that of dilating the pupil of the eye—when applied externally being so powerful, in many cases I desisted from making it so strong, and, with the sanction of the Dispensary Committee, reduced it to one part to nine. Mr. Gerrard now says that even this has been found in some cases too strong, and raises an eruption when persons are at all subject to any erysipelatous tendency. It may therefore be necessary in some cases to make it more dilute. Lead plaster, which makes it sufficiently adhesive, is to be preferred to resin plaster, as the resin may assist in producing the eruption sometimes complained of. With regard to the merits of the two kinds of plasters made with alcoholic extract from the leaf, and that made from the root, I think one great objection to that prepared from the leaf is that it is a deeply-coloured plaster. In the Pharmacopœia process the alcohol naturally absorbs the colouring matter of the extract ; and although I believe that chemists prefer it with the bright green colour, it is very disagreeable to the patient who has to wear it. I therefore prefer it made from the root, and seeing the good effect of liniments so produced, I cannot see any advantage in the preparation from the leaf. I believe, as a sedative plaster in allaying pain of various kinds, especially in affections of the heart, it is very valuable.

Mr. HAMPSON : I entirely agree with what Mr. Martindale has said, and having had some experience in making belladonna plasters from the root and from the leaf, I am inclined to think—in fact I am sure—that that prepared from the root is better in every respect.

Mr. MARTINDALE : I should like to ask Mr. Gerrard if it is quite correct where he says that when the oxide of lead is dissolved in vinegar in making Emplastrum cerati saponis, a solution of subacetate of lead is produced ?

Mr. GERRARD : The calculated proportions of lead and acid would leave a subacetate.

The President: With regard to the Emplastrum opii, perhaps some gentleman can offer an opinion as to the relative merits of the powder and the extract.

Mr. Martindale: There is a great advantage in using the extract if it can be mixed in the way Mr. Gerrard has suggested. I have not tried the experiment of dissolving it in glycerine, and getting the solution to mix with the basis; but if it does mix it will be a decided improvement over the use of powdered opium, because, as Mr. Gerrard has pointed out, in spreading such a plaster you are apt to get the powder agglomerated together in particles.

Mr. Gerrard: There is a sample of each of the plasters on the table.

Mr. Giles: From my experience I prefer the plaster in the form in which we now have it, by reverting to the old Pharmacopœia process, using the powder instead of the extract, as being much more convenient to make. I cannot say that operating in the small quantities one requires for one's own use, I have found any difficulty in mixing in the powdered opium, though it may be a difficult matter in making a large quantity. But you have a considerable difficulty in mixing the extract, and I must therefore say I was very glad to find that we had reverted to the old method.

The President: If you use the extract, it is important to have it well diluted, because, if you try to mix it up too stiff, you cannot do it.

Mr. Umney: With regard to the Emplastrum plumbi, I look upon the present proportions given in the Pharmacopœia as a mistake. The proportions given in the London Pharmacopœia, as far as I can remember, would be about five parts of litharge to nine by weight of olive oil; but in the B. P., the litharge has been decreased to four parts, and herein I think is a very serious error. In fact, almost all the plasters of the B. P. on this account are too sticky, and I think a much better plaster can be prepared by using the formula of the London Pharmacopœia; it is too, in my opinion, a better basis for other plasters.

Mr. Martindale: With regard to this plaster, as I have said before in this room, the Pharmacopœia directions are somewhat vague, and I should like to hear the best mode of getting rid of the aqueous moisture, and also of the glycerine contained in it. Makers generally like to send it out opaque, white and free from discolouration; though, in my opinion, it should never be white, but of a somewhat translucent appearance, something like ordinary fresh yellow resin; it is only when we get it evaporated to that consistency that it is in a fit state for spreading by a machine. Mr. Gerrard can corroborate me that it is impossible to try to spread a plaster such as is generally sent out by wholesale druggists by a machine; it contains too large a quantity of water and some portion of glycerine, and unless they are evaporated out by continued stirring and heat, it is impossible to get the plaster when passed through the machine, or even when spread by hand, to take the cloth; it will not "bite," and you often get a large piece in the centre which is not coated at all. I should like to know if it would be well to pour the plaster, when nearly finished, into a large quantity of water, and knead it so as to wash out the glycerine.

Mr. Gerrard: My own experience is that the heat can be continued after the union has taken place between the oil and the lead until the whole of the moisture is evaporated. The plaster then assumes a semi-opaque appearance; it retains a little glycerine, but that is not at all a disadvantage. The larger portion passes off with the steam, and the small portion which remains is, according to my experience, an advantage, because it renders the plaster more flexible; too much, however, retards its adhesion. In the plaster sent out by some wholesale houses, the object seems to be to retain as much water as possible.

Professor Redwood: I should like to make one observation with respect to the subject now before us, the Emplastrum plumbi, mainly arising from what has fallen from Mr. Umney, who has referred to the alteration made some years ago in the proportion of oxide of lead and olive oil. That alteration was made after a very considerable investigation of the subject mainly amongst those practically engaged in making plasters upon a large scale. One remark of Mr. Umney's tends rather to confirm the propriety of the conclusion then come to, for he stated that the plaster is rendered more sticky in consequence of the alteration in the proportions. Now, that is the very object that was contemplated. You are probably aware that many years ago there was a plaster much used in London, known by the name of Dr. Scott's plaster; it was, in fact, a plaster used by a medical man celebrated in wound cases at that period. It was much sought after by many persons, and for a considerable time there was a good deal of mystery as to the way in which it was prepared. It was sufficiently adhesive, but was entirely devoid of the ordinary source of stickiness in adhesive plaster. The object contemplated in the alteration referred to was to give to the plaster a certain amount of adhesiveness without the addition of resin. That has been accomplished by the alteration in the proportion of the ingredients, and it certainly is more sticky. Mr. Squire has just reminded me that I omitted to notice one element in the new plasters, namely, long boiling. That, together with the increased proportion of oil, are the means by which the Emplastrum plumbi is, as we conceive, now produced, which possesses adhesive properties.

Mr. Giles: I think what has been said is a very sufficient answer to the remarks made with regard to Emplastrum plumbi as a plaster standing by itself, but it leaves us in the same embarrassment with reference to the production of this plaster as a basis for other plasters. Undoubtedly the consequence of the change has been to make the other plasters of the Pharmacopœia inconveniently sticky; and, as a matter of fact, I believe wholesale houses have modified the form, and that we do not now get them strictly according to the B.P. I do not know that there is any harm in that, but in a future edition it might be advisable to introduce an Emplastrum adhesivum where a sticky plaster is required, and the old Emplastrum plumbi as a basis for other plasters. I recollect a great many years ago noticing a peculiar plaster which is used in France under the name of adhesive plaster; it is much softer than our own and excessively sticky, and it has this great advantage, that you can apply it with facility to a sore, and can take it off again. It is a very useful plaster in many cases in surgery.

The President: Does that French plaster contain much resin, because that would be rather an irritant constituent?

Mr. Giles: I do not know.

The President: The next plaster on the list is the Emplastrum plumbi iodidi. In one of the plasters exhibited on the table, undoubtedly the ordinary iodide of lead is not present, but it may be more efficient than the other.

Mr. Martindale: I think the explanation given with regard to the iodide of lead plaster is scarcely that which either Mr. Gerrard now states or Dr. Redwood gave some time ago in this room. I believe the lead plaster dissolves the iodide of lead without decomposition, and that the decolorization is not so much due to the soap which it contains as it is to the lead plaster. If a little more heat had been applied, I think Mr. Gerrard's yellow plaster here would become quite colourless. I once tried the experiment, and though I should like to repeat it before speaking positively, I found I got the iodide of lead dissolved by the lead plaster, and that it became decolorized just as much as the Pharmacopœia plaster.

Mr. Gerrard: My experience of that plaster is, that if the lead plaster is made according to the B.P., an excess of oil being used, the iodide of lead is really decomposed with the addition of soap or resin, and more especially so with the Pharmacopœia lead plaster than with one made with a large proportion of litharge. It is very curious that in the combination which takes place no iodine is evolved.

Professor REDWOOD: There is no doubt that the present formula for preparing iodide of lead plaster is a mistake. I believe, of course, that the iodine is present, and it may be in as active a condition as if it remained iodide of lead, but the very fact that the plaster changes its colour is an objection. The reason why the other plaster was ordered in that formulary was, that it makes a plaster which retains its flexibility better. The one made smooth with lead cracks very easily, whilst one made with soap retains its flexibility.

Mr. MARTINDALE: I believe it was first intended to be an iodine plaster, but it was found, in making it, an iodide of lead plaster was formed, and that it became like like the ordinary lead plaster in colour. In giving directions for another iodide of lead plaster, I think clear instructions should be given, so as to get the iodide of lead, if soluble, dissolved in the lead plaster, and not to have that uncertain, changeable yellow colour. With regard to the Emplastrum resini and Emplastrum saponis, I do not see why they should both be retained, as they contain the same ingredients, only in rather different proportions. It is inconvenient to have to keep stocks of so many different kinds of plasters which are seldom used.

The PRESIDENT: I think the Emplastrum saponis is a redundancy. It is generally kept about until it will no longer stick to the calico, and then it is thrown away.

(*To be continued.*)

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of the above Society was held on Wednesday, July 1st, under the presidency of M. Planchon. The chairman announced that M. Chatin had been elected a member of the Academy of Sciences in the place of the late M. Gay, and he remarked that this nomination was an honour to the Society of Pharmacy, M. Chatin being one of its honorary members. Amongst the papers which had been received were the following:—

A note from M. Stanislas Martin upon the textiles furnished by the residues of the manufacture of cane sugar, accompanied by specimens of the crude filaments of the cane trash, and of the paper pulp obtained from that substance.

A letter from M. Demetrius Phollides, of Bucharest, thanking the Society for its reception of a former note on emulsions, and containing some practical observations upon the preparation of compound suppositories. The process he prefers is to triturate the fat body in a mortar with the active substance previously pulverized, and to add a few drops of oil of sweet almonds so as to obtain a homogeneous paste, which is divided and afterwards shaped by the hand into the proper suppository form.

A memoir by M. Carles, of Bordeaux, upon iron reduced by hydrogen, and the use of a titrated solution of iron as a means of ascertaining its purity. In reference to this subject, M. Bussy remarked that the sulphide which exists in nearly all the reduced iron of commerce presents more inconvenience than the oxide of iron which had specially occupied the attention of M. Carles. M. Bussy added that formerly, for ascertaining the quantity of metallic iron contained in reduced iron, he employed a solution of sulphuric acid, and measured the volume of hydrogen produced.

M. Adrian presented, on behalf of M. Nativelle, a note on a new method of preparing crystallized digitalin. This it is proposed to publish in a future number.

M. Lefort presented a note by M. Brètet, of Cusset, on Dragon's-blood and its adulterations.

M. Méhu communicated to the Society an investigation which he had undertaken upon the density of cholesterin.

M. Ferdinand Vigier presented a memoir entitled "The Preparation of Cinchona Wine and the Estimation of the Alkaloids that it contains."

THE INTERNATIONAL PHARMACOPŒIA.

M. Boudet then read a report which he had drawn up, and which it was suggested might be used for a preface to the projected International Codex. The text of this report has not at present been published, but its tenour is indicated somewhat by the discussion that follows:—

M. Bussy thought it was not necessary to speak of secret remedies or to omit from the international formulary certain preparations which were perhaps a little empirical, but much used. He considered it would be best to leave to each country its usages. He insisted upon the importance of the definitions and tests of the primary substances which should be indicated in the work.

Dr. Poggiale disagreed with M. Bussy as to the passage respecting secret remedies. He had heard that part of the report with lively satisfaction; he wished the Society to oppose strongly not only secret remedies, but also the special remedies which are not contained in the Codex, and which do such grave injury to the interests and reputation of pharmacists. He was of opinion that the report of M. Boudet should not be modified, and that their delegate should be empowered to defend the principles of the Society at the St. Petersburg International Congress.

M. Boudet informed M. Bussy that the commission had not modified the formulæ—sometimes not very scientific—which it had taken from the pharmacopœias of different nations; it had sought, however, as much as possible, to produce a work which should be abreast of the progress of science. As to secret remedies, he had thought it his duty to speak of them, in order that foreign pharmacists, who were very hostile to them, might see that the Paris Society of Pharmacy shared their views upon the subject.

M. Hoffmann thought that France was wrong in retaining in her Codex certain old formulæ which might be replaced by more rational preparations.

To the explanations already given, M. Mayet added that the commission had selected, and not modified, formulæ, and that the International Commission would be at liberty to introduce new ones, since the work which is to be presented at St Petersburg will be entirely provisional. He said further that the weights employed in England and America had created some difficulties in the expression of the quantities, and that the commission had proposed by the side of the true formulæ others which were very slightly modified, but more simple.

M. Boudet announced that the Pharmaceutical Society of Great Britain had appointed two delegates to represent it at the Congress at St. Petersburg.

The subject was then discussed in committee, and M. Méhu was selected to represent the Société de Pharmacie de Paris at the International Congress.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

On Thursday morning, August 20th, the meetings of the sections commenced. In section A (Mathematical and Physical Science), which met in the Queen's College, the President, the Rev. Professor J. H. Jellett, delivered an address in which he discussed the tendency of scientific progress to a reduction of all physical science under the power of mathematical analysis, in the gradual development of connexions between the different members of that great group to which we give the name of physical science. Among the instances of such growing relationship, he alluded in the following words especially to the—

CONNEXION BETWEEN OPTICS AND CHEMISTRY.

"In speaking of the connexion between Optics and Chemistry, the topic which will occur first to every one is the spectroscope; but on this part of the subject it is not necessary that I should dwell. It has so largely occupied the attention of physicists, and has been so fully treated by those who have made it their special study, that I could not hope to add anything to what they have said.

I would only observe that the spectroscope has enabled chemistry to overleap a barrier which Comte pronounced to be insurmountable, and which would have excluded from the objects of chemical research anything lying without the limits of our earth. Comte warned us that our knowledge of the planetary worlds was necessarily limited to their geometrical and mechanical properties—to the nature of their movements, and the forces by which they are produced—and that all inquiry into the constituent elements of the planets or their atmospheres was for ever, and by the necessities of the case, interdicted to us. But the spectroscope has told quite another story.

"But there is another point of contact between optics and chemistry,—another spot on the border-land between these two sciences which, I think, promises also to be fertile in discovery—I mean the use of polarized light as an instrument of chemical analysis. It is true that the application of this instrument is limited in its extent. The physical property on which this application depends, namely, the power possessed by certain liquids to change the plane of polarization of a transmitted ray, or, as it is commonly called, the rotatory power, is altogether confined to the organic world, and it is not universal even there. Still, within this limited range, the application of polarized light is capable of solving, or aiding to solve, chemical problems which chemistry proper would probably find very difficult. Let me give you two examples.

"1. Is it true that an acid salt is decomposed by solution? Or, taking the question in another form: If to a solution of a neutral salt there be added, atom for atom, a quantity of its own acid, does that additional atom of acid enter into combination, or does it remain free? It has been usually inferred from the thermic researches of Dr. Andrews, followed up by Favre, Silbermann, Berthelot, and others, that the second alternative is the true one, the solvent being water. Now, if the problem be varied a little by making spirit the solvent, the application of polarized light gives us this important information:—

"If to an alcoholic solution of the ordinary nitrate of quinia there be added an additional equivalent of acid, this additional equivalent *does* enter into combination with the nitrate.

"This information leaves to us the alternative of supposing that the ordinary nitrate, sulphate, etc., of quinia are not neutral but basic salts, or of admitting that an acid salt is not always decomposed by solution, at least in spirit.

"2. When an acid is added to a solution containing two bases, the salts formed being also soluble, does the acid divide itself between the bases? and if so, what is the law which governs the division?

"The application of polarized light enables us to solve this question for some of the organic bases, proving that there is a continuous partition of the acid, and enabling us in one case, and probably in many others, to assign the law according to which the partition is made.

"One more instance may suffice to exemplify the advantage which chemistry proper has already derived from its union with optics. I take this instance from the general problem of saccharometry.

"We have long known how to analyse, both optically and chemically, a solution containing two kinds of sugar, one of which is sucrose. But, as each of these methods gives but two equations, it is plain that neither is sufficient where the unknown quantities are more than two. If, then, as is very commonly the case, there are present in the solution three kinds of sugar, we cannot obtain a complete analysis, either from optics or from chemistry. But, as Dr. Apjohn has recently shown, this problem, insoluble by either method taken alone, is readily solved by a combination of both methods. An important step is thus made in the application of optics to chemistry. Instead of merely giving to chemistry a new solution of a problem which chemistry could solve without any assistance, optics has aided chemistry to solve a problem which chemistry unaided might have found very difficult."

B. Chemical Section.

In this section the proceedings were opened by an Address from the President, Professor A. Crum Brown, on Chemical Constitution. The Address will be found printed at page 163.

Amongst the papers set down for reading before this section were the following:—

Thursday, August 20th.

Professor G. C. Foster—On Siemens' Pyrometer.
Professors Roscoe and Williamson—Report of Committee for superintending the monthly reports of the Progress of Chemistry.
W. Chandler Roberts—Report of Committee on Essential Oils.
Professor Hodges—The Chemical Composition of Jute Fibre.
Professor Brown and Dr. E. A. Letts—Methyl-thetine.
Dr. C. R. Wright—On some Opium derivatives.

Friday, August 21st.

Professor Corfield—Report of the Committee for the Utilization of Sewage.
Dr. Carpenter, F.R.S.—On the replacement of Organic Matter by Silicious Deposits in the process of Fossilization.
Professor Hodges—On the Silicified Rock of Lough Neagh.
Professor Roscoe, F.R.S.—On a self-registering Apparatus for measuring the Chemical Action of Light.
Professor Roscoe, F.R.S.—On certain abnormal Chlorides.
Professor Thorpe—On the Specific Volumes of certain Liquids.
Messrs. Braham and Gatehouse—On the Dissociation of Nitric Acid.

Monday, August 24th.

Professor Andrews, F.R.S.—Experiments at High Pressures.
Dr. Dewar—On the Latent Heat of Liquefied Gases.
Dr. Dewar—Report of the Committee on the Estimation of High Temperatures.
Professor Debus—On Spontaneous Generation, from a Chemical point of view.
Mr. Ogilvie—On the Estimation of Phosphoric Acid as Pyrophosphate of Magnesia.
W. Jesse Lovett—On an improved form of Filter Pump.
Professor Emerson Reynolds—Notes on the preparation of the Sulphur-Urea.
Professor Emerson Reynolds—On the action of the Sulphur-Urea in Metallic Solutions.
Lowthian Bell, F.R.S.—On the joint action of Carbonic Acid and Cyanogen on Oxide of Iron and on Metallic Iron.
Professor Gladstone, F.R.S., and Mr. Tribe—Electrolytic experiments on Metallic Chlorides.
Chandler Roberts—Gold Assays.
Professor Hodges—Analyses of Indian Teas.
W. J. Cooper—Composition of certain kinds of Food.

Tuesday, August 25th.

Professor Maxwell Simpson, F.R.S.—On the Chlor-Bromides and Brom-Iodides of the Olefines.
Professor Andrews, F.R.S.—On an Aspirator.
Professor Delffs—On an Aspirator.
Mr. Fairley—New reactions of Oxygen, Chlorine, Peroxide of Hydrogen, Hypochlorous Acid, and Ozone.
Mr. Fairley—Hypochlorous Acid and Ozone. Synthesis of Perchloric Acid.
Professor Clifford, F.R.S.—On the General Equations of Chemical Decomposition.
Dr. T. L. Phipson—On the presence of Cyanogen in Commercial Bromine, and a means of detecting it.

Dr. T. L. Phipson—On a Sesqui-sulphide of Iron.
Professor Armstrong—Report on Isomeric Cresols.
W. Charley J.P.—On the injurious effects of "dew-rotting" Flax.

D. Biology.

In the department of Zoology and Botany of this section, on Friday, the President, Dr. Hooker, delivered before a crowded audience an Address on the Carnivorous Habits of some Plants. In moving a vote of thanks, Professor Huxley expressed a hope that the Address would be published; and in a future number we shall probably be able to reproduce it.

E. Economic Section.

The Metric System.—In the Economic Section, on Saturday, the Report of the Metric Committee was read, in which they "reiterate their firm conviction that the uniformity of the weights, measures, and coins will tend to the economy of time in the ordinary transactions of life, the extension of education and science, and the general advance of commerce and international intercourse."

Reform in the Work of the Medical Profession.—On Monday, in this section, Miss Mary E. Theedy, M.A., read a paper so entitled, in which she said:—

"The work of the medical profession at the present time seemed to be remedial rather than preventive, and physicians attained fortune and reputation for the most part not by preventing the occurrence of diseases, but by effecting remarkable cures from protracted or severe cases. As medical practice was at present conducted, a strong temptation was unavoidably offered to physicians to promote rather than prevent ill-health. It would be better for the morality of the profession, as well as the health of society, that the physician should assume such a relation to those under his care that his reputation and income should depend upon his success. Such a relation towards society would give the practitioner the keenest stimulus to acquaint himself with all the conditions that affected the health and physical development, and also the strongest inducement to enforce correct physical habits upon those under his care. She suggested a new system for the education of physicians, and the employment of male physicians for men and woman physicians for women."

A short discussion followed, in which a general opinion was expressed that ladies should be admitted to the practice of medicine, especially among women and children, but that no ground whatever existed for making any change as to medical men, who were well known to have written and laboured in the most disinterested manner for the prevention of disease.

Sir John Lubbock's Lecture.

On Friday evening, Aug. 21, a lecture was delivered in the Ulster Hall, by Sir John Lubbock, on "Common Wild Flowers considered in Relation to Insects." We hope to print the lecture in a future number.

Professor Odling's Lecture.

On Saturday Professor Odling delivered a lecture in the Workmen's Institute, before a crowded audience, on the "History of the Discovery of Oxygen"

The Next Meeting of the Association.

On Tuesday a meeting of the General Committee was held at 3 o'clock p.m. Sir John Hawkshaw was unanimously appointed President for the meeting in 1875 which is to be held at Bristol, on the 25th August. A deputation from Glasgow invited the Association to visit that city in 1876, and it was unanimously resolved to accept the invitation. A deputation from Plymouth urged the claims of that town for a visit in 1877.

Concluding Meeting.

The concluding general meeting was held in the Ulster Hall, on Wednesday. Mr. Griffiths, the assistant secretary, read a list of the papers which had been discussed in the different sections, and mentioned that the number of tickets issued amounted to 1950.

Various votes of thanks were passed to the local authorities to whom the Association was indebted for accommodation during its meeting, and a vote of thanks to the Preisdent brought the business to an end.

It is stated that no less than nine different excursions have been arranged, one being to the Giant's Causeway, to which numerous invitations have been issued by the Mayor of Belfast.

Parliamentary and Law Proceedings.

Prosecution under the Adulteration Act.—Alleged Adulteration of Red Precipitate.

At the Hyde (Cheshire) Petty Sessions, on Monday, Mr. Samuel Booth, chemist and druggist, was summoned at the instance of Captain Arrowsmith for selling to him, on the 9th July, as unadulterated, half an ounce of red precipitate, which was, to the defendant's knowledge, impure.—Defendant pleaded, Not guilty.—The Clerk informed defendant that the Act of Parliament said he was to prove that the article was pure, and unless he did so he was supposed to have a knowledge of the adulteration. Captain Arrowsmith was not bound to prove that it was adulterated. Defendant was to show that he did not know it was.—Defendant said he did not know it was adulterated. He sold it as he bought it.—The Clerk: Chemists ought to be very careful indeed.—Captain Arrowsmith stated the case. He said that on the 9th of July he purchased from Mr. Booth, who was a chemist and druggist at Broadbottom, an ounce of red precipitate. On the following day he conveyed it to the county analyst, from whom he had received a certificate, which stated that the article had been analysed and found to contain five parts per cent. of oxide of lead. The Captain further observed that red precipitate was used very largely by people as an ointment, and it was very necessary that it should be pure. He had procured other articles from Mr. Booth, among which was some white precipitate, and it was found to be pure. He had no wish to press for a heavy penalty. Probably Mr. Booth had been taken in by the dealer, and he would not say that Mr. Booth was aware of it.—Defendant said he was very sorry. He had been in business above thirty years, and he had never had any complaints before. He should be on his guard in future.—Captain Arrowsmith said it was very necessary that the public should be protected. The Bench said it was possible that the precipitate powder was as defendant received it, but it must be understood that it was the duty of all people who sold drugs and other things which concerned the health of the inhabitants to know beforehand that they were pure.—The case was dismissed on defendant's promising to pay the costs.—*Local Newspaper.*

Suicide of a Chemist and Druggist.

An inquest has been held, at Cardiff, on the body of Mr. David Benjamin Jones, chemist and druggist, late of Adam Street, Newtown.

It appeared from the evidence that on Tuesday morning, August 11, about a quarter to eight, he ran into the house of his next-door neighbour, and exclaimed, "Let me sit down; I shall be dead in two minutes." He immediately began to show symptoms of internal suffering; medical assistance was obtained, and the usual remedies were speedily applied, but without avail.

Dr. Buist said that he was called to see deceased, and found him on the floor, apparently unconscious. Deceased afterwards said he had taken laudanum, but after making an examination witness asked him whether it was not strychnine. Very soon afterwards deceased went into violent convulsions, his whole body becoming rigid, and his teeth clenched; he never really recovered from this, gradually relaxing and dying. Some hours afterwards witness examined the powder found by Sergeant Wallbridge, and felt sure it was strychnine; Mr. Drane, chemist, was of the same opinion. He had no doubt Mr. Jones died from the effects of strychnine, and he thought it right to add that he believed deceased had been of unsound mind for several days previously.

The jury returned a verdict that the deceased had taken the poison from which he died while he was in a condition of unsound mind.—*Hereford Times.*

Suicide by Laudanum.

An inquest was held at the Sunderland Infirmary, on Tuesday, August 11, by Mr. Coroner Maynard, concerning the death of a man who had been found by a police-constable in the street in an insensible condition. Two small bottles had been found upon deceased, which were labelled "Laudanum," one being empty, the other full.

Mr. William Leavenswaite, junior house-surgeon at the Infirmary, said he was present when the deceased was brought to the institution in an insensible state, not being able to give any account of himself. He heard some one remark that deceased had taken laudanum, and he and Mr. Hopgood commenced to apply the different remedies. The face of the deceased was livid, and the pupils of his eyes were contracted. They treated deceased on the assumption that he had poisoned himself. They did not examine the body to see whether there were any wounds to cause the insensibility; they only examined the head. The deceased was brought into the Infirmary at half-past two o'clock, and died at half-past three. He was of opinion that deceased died from opium-poisoning.

Mr. Jeremiah Burton Gilbert, chemist and druggist, trading under the name of Sayers and Gilbert, at Monkwearmouth, said deceased was a stranger to him. On Monday morning, about a quarter past nine, he sold deceased twopenny-worth of laudanum in a bottle which was labelled "Poison." Asked deceased what he wanted it for, and if he knew how to use it, and he said he used it for the tic-doloureux, and he perfectly understood the nature of it. He appeared to be perfectly cool and collected when he purchased it, or witness would not have sold it.

A long discussion here took place as to the meaning conveyed by the label on the bottle, which was to the effect that the contents of the bottle were "soothing and narcotic," and "twelve to twenty drops could be taken, according to the constitution of the patient."

Mr. Sanderson, of whom deceased purchased a bottle of laudanum, said that laudanum was "soothing and narcotic" only to a certain extent.

The Coroner: Now, don't you think that twenty drops is a very large dose for a weak person who has never taken it before?

Mr. Sanderson considered it a strong dose, but not sufficient to do harm.

The Coroner thought that the label was a miserable advertisement from the beginning to the end, and he was only sorry that there was not an Act of Parliament to stop it at once. He really believed that the deceased had died from taking a dose of opium, and that there was no evidence as to what state of mind he was in at the time he took it.

The jury, after a short consultation, identified deceased as James Henry Sinclair, and that he "Died from poison administered by his own hand while in an unsound state of mind."—*From the Sunderland Times.*

Review.

Tea, Coffee, and Cocoa Analysis. By J. Alfred Wanklyn, M.R.C.S., &c. London: Trübner and Co.

This book, we learn by the preface, "is intended to form one of a series of manuals for the use of Public Analysts under the Adulteration Act," for which purpose we certainly consider the book but very imperfectly adapted. After the well-known and deservedly valued works of Mr. Wanklyn on the analysis of water and of milk, it is disappointing to find that his latest contribution to scientific literature bears unmistakable signs of having been hastily compiled from the works of others, and apparently without the author having taken the trouble to verify their results for himself.

How far Mr. Wanklyn is from having succeeded in rendering his work complete, is evident from the fact that we find no allusion throughout the book to facing or colouring of tea, or to adulteration by ferruginous matters or catechu; admixture with other leaves is barely mentioned, and their botanical characters are left quite unnoticed, while the tea-leaf itself is stated to "bear some resemblance to the willow."

On page 3, the author observes that "in the tea trade, the besetting malpractice is the selling of partially exhausted tea, and the main efforts of the tea analyst should be directed to this form of adulteration; therefore Mr. Wanklyn gives special attention to the detection of this admixture, relying for this purpose on the per-centage of soluble ash, the proportion of tannin—Allen's process of titration by means of lead being described at length—and on the per-centage of extractive matter. The last method is founded on the old determinations of insoluble matter by Péligot, the author preferring to evaporate the aqueous solution, rather than to weigh the redried leaves.

Mr. Wanklyn also proposes to apply his well-known ammonia process to the examination of tea extract, based on the assumption of the constancy of composition of natural products like milk and tea. Apparently upon the strength of the examination of a single sample of tea for "albumenoid ammonia," which gave ·70 per cent., Mr. Wanklyn ventures to "confidently recommend this method of investigating the strength of tea-infusion," actually in the face of the only two comparative experiments, by which he obtained ·495 and ·50 per cent. of albumenoid ammonia from gooseberry leaves and Paraguay tea respectively! We are not informed what evidence Mr. Wanklyn has that other samples of tea would not have yielded as little ammonia as the gooseberry leaves, or what possible value there could be in a determination that shows so slight a distinction between tea and other leaves.

Mr. Wanklyn commits a similar error in the chapter on theine, where he says it would be a mistake to regard the varying amounts of theine recorded to have been found as showing that the actual proportion of theine was very variable. Yet it does not appear that Mr. Wanklyn has made any experiments in support of this statement, and he merely gives Péligot's process for the extraction of theine.

The section on coffee contains nothing that is new, and the article on cocoa is chiefly compiled from Mr. Holm's recent lecture before the Society of Arts, which was fully reported in our columns.

Almost the only novel matter in the book is that taken from Mr. Allen's articles on tea and coffee, and we are informed that the absence of all allusion to some very recent papers by Mr. Allen and Mr. Wigner is to be ascribed to the fact that part of the book has been in type since the beginning of May.

Notes and Queries.

CHLORAL HYDRATE SUPPOSITORIES.—The following formula for suppositories containing chloral hydrate is published in the *Journal de Pharmacie* (August, p. 128) by Dr. Constantin Paul :—

Cacao Butter	11	grams.
White Wax	7	„
Chloral Hydrate	6	„

For six suppositories.

[407.] COUGH MIXTURE.—Can any correspondent furnish me with a formula for making Cough Mixture, with honey, that will not ferment.—M.P.S.

Correspondence.

The Sessional Prizes.

Sir,—I agree with "*Fairplay*," whose letter appears in your last week's issue, that it is unfair that the man who carries off the Pereira Medal should be allowed to take the Prize of Books in the same year. But with the latter part of his letter I do not agree. He considers that any who competed, coming from a distance, must be devoid of sense. Those who did not win, and who risked "travelling expenses on only a chance of success" are doubtless very much obliged to him for the compliment. Happily men do not sit down and calculate the exact money value of prizes of this kind. Doubtless some of them had spent years in patient study, the time of study being drawn from that which should have been spent either in bed or in taking that amount of outdoor exercise which is so essential to health; and it is not likely that these men would be debarred from competing by the cost of a trip to London, especially as these prizes are the only ones open to men who have not spent a session at Bloomsbury Square, although they might feel the circumstances otherwise than encouraging.

All cannot win either the Pereira Medal or the Prize of Books, but unless a countryman does either the one or the other, he is no better off, so far as recognition by the Society is concerned, than the man who just manages to shuffle through his examinations: his name is placed at the head of the month's list, certainly, but the man himself has nothing to show. I think an extra certificate ought to be given, at least, to the men who pass the "Major" in Honours, and surely a second prize and certificates of merit might be awarded to men who were at all deserving in the competitions before mentioned.

It having been decided by the Council that the examinations for the Pereira Medal and Prize of Books should only be held in London and Edinburgh, I think the Council ought to defray the travelling expenses of the competitors.

A Country Pharmacist.

An Easy Method of taking the Specific Gravity of Thick Liquids.

Sir,—Being engaged in a pharmaceutical laboratory, where the preparation of liquid extracts, etc., are frequent operations, and as the specific gravity of many of these has to be taken before an accurate result can be arrived at, I have been much annoyed by the length of time required for properly cleansing the specific gravity bottle and filling the same with a thick liquid.

The necks of specific gravity bottles are usually so small as to necessitate the introduction of a thick liquid into the bottle by mean of a pipette and in the case of some such liquids (e.g., Ext. glycyrrh. liq., B.P.,) this causes the formation of many air-bubbles, which take some time to disperse; I ha e therefore found the following modification of an old and very well known method to be useful. The plan I adopt is this:—

I attach a piece of glass (a glass stopper answers well) by means of very fine platinum wire or horse hair, to one of the limbs of a balance, and find the weight in air is 667·9 grains, its weight in water is 372·6 grains. This shows that a bulk of water equal to that of the glass weighs 295·3 grains. Immersed in a non-official syrup, I find the glass weighs 280·6 grains; this also shows that the weight of a bulk of syrup equal to that of the glass is 387·3 grains, thus showing us the weights of equal bulks of water and syrup.

By a simple division sum we can of course immediately get the specific gravity of the syrup in question,

$$387{\cdot}3 \div 295{\cdot}3 = 1{\cdot}311.$$

For as the loss of weight in water is to the loss of weight in syrup so is 1·000 to the specific gravity of the syrup.

I have tried this method for other liquids with equally good results, but of course for limpid liquids the specific gravity bottle when at hand stands unequalled.

I do not place this before you as by any means a novel method, but I think it is one the usefulness and simplicity of which has been long overlooked, the advantages of the above process being that the specific gravity of any liquid can be accurately ascertained with much less trouble and in much less time than by means of the specific gravity bottle. And if a piece of platinum weighing about 10 grains be used (as was suggested by the original inventor of this method) instead of a piece of glass, the specific gravity can be accurately ascertained with as small a quantity as one fluid drachm of the liquid.

Norwich. W. H. Symons.

J. E. Hoult.—'How Crops Grow,' published by Macmillan, or Liebig's Letters on Agricultural Chemistry, and the papers by Lawes and Gilbert in the Journal of the Royal Agricultural Society of England.

Pharmaceutic.—You are recommended to apply to the Director of the Royal Gardens at Kew.

"*Ignoramus.*"—(1) Read the Preface to the Pharmacopœia. (2) The information would be best obtained by practical lessons in a laborato-y. (3) You do not say whether you want a recipe to produce them or to get rid of them; but in either case consult a bootmaker.

R. and J.—Probably washing with alcohol.

"*Echo.*"—It is usually about the same specific gravity.

X. Y. Z.—We must refer you to the Public Analyst of your district.

"*Smilax.*"—Your letter has been handed to the Secretary, with whom you are recommended to communicate.

G. R. G.—Good descriptions of the process are given in 'Ure's Dictionary of Arts, Manufactures,' etc., vol. i., and 'Muspratt's Chemistry,' vol i.

"*Socius.*"—The formula for Driffield Oils given in Cooley's Druggists' General Receipt Book is—Barbadoes tar, 1 oz., linseed oil, 1 lb., oil of turpentine, 3 oz., oil of vitriol, 1 oz.

"*Ceterach.*"—The medals are awarded by the Council upon the reports of the Professors. If you have any suggestion to make, or wish for information respecting any supposed irregularity, you are recommended to communicate with the Secretary.

A. P. S. and P. B. are referred to the regulation respecting anonymous communications.

W. S. T.—It would be unsafe to express an opinion without an inspection of the mortar. We thank you for your communication, but the rhymes are unsuited for publication in this Journal.

J. E. R.—We think the safest aud most economical plan would be to sacrifice the socks.

H. W. Harris.—A hydrocarbon oil, so called because first obtained from Rangoon petroleum, being the heavy portion of the distillate.

W. S.—The formula you ask for was given in volume i. of the present series, p. 446.

E. M. Smith.—The fault, we think, probably lies with your tartarated iron. Try another sample, dissolve it separately, and mix with the solution of the other salts.

W. Hallawell.—You are not too late to compete. You are recommended to read again the announcement carefully; nothing is said therein about giving notice in May.

C. Hawthorne.—You are recommended to communicate your views to the Secretary.

Communications, Letters, etc., have been received from Mr. Rimmington, Mr. Pollard, Mr. Darby, G. [illegible]

THE PRICE OF MEDICINE IN 1836 AND 1874.

BY CHARLES EVE.

In this slack season of the year when so many of our customers are enjoying a holiday, I have found time to classify several hundred formulæ taken from two of our prescription-books belonging respectively to the years 1836 and 1874. The result will surprise few who have given any thought to the subject, but it will serve to show, in strong relief, the altered character of modern prescribing, and the serious loss it entails on the dispenser. Let me add, that beyond the exclusion of external remedies, there was no selection of the formulæ; they were taken in the order in which they were copied.

	1836.	1874.
Mixtures, dose ℥ij and upwards	5·5 per cent.	1·5 per cent
" " ℥iss "	14·0 "	4·5 "
" " ℥j "	11·5 "	23·5 "
" " ℥ss "	1·0 "	17·5 "
" " ʒij "	2·0 "	2·5 "
Drops, " ʒj or less	5·5 "	10·5 "
Pills	42·0 "	32·0 "
Powders	7·5 "	5·5 "
Draughts	10·0 "	1·0 "
Electuaries	1·0 "	0·5 "
Suppositories	—	1·0 "

In 1836, the price of 50 bottles of mixture and drops, containing 338 doses, was £5 9*s.* 10*d.*, being rather more than 3¼*d.* a dose.

In 1874 the price of an equal number, containing 618 doses, was £5 11*s.* 8*d.* or almost exactly 2*d.* a dose, showing a difference in favour of the purchaser, in 1874, of rather more than 1½*d.* a dose.

Plough Court, E.C., August 28th.

NOTES ON A NEW PREPARATION OF MEAT

BY S. DARBY.

A preparation of meat claiming to possess very considerable renovating powers has lately been introduced to the notice of the medical profession in Germany. As the nature of it appears to have been altogether misunderstood in this country, whilst the name given to it would foster this error, a slight note as to its constituents may probably be of interest.

The preparation referred to is named the "Leube Rosenthal'sche Fleisch solution," and the method given by Dr. Mirus, in the *Chemisches Centrall Blatt* of July 16th, 1873, for its production is as follows:—

"Two hundred and fifty grammes of finely minced meat are put into a half-quart mineral water bottle; this is then filled to three-fourths of its contents with water to which has been added 1 per cent. of hydrochloric acid, and the lumps of meat broken up by well shaking. The bottle and its contents are placed in a steam boiler and heated under pressure for fifteen hours continuously. The bottle is now removed and the mixture rubbed up, so as to obtain it in a uniform state, after which it is again heated as before for fifteen hours. The acid mixture is to be exactly neutralized with carbonate of soda, and evaporated to the consistence of gruel.'

This preparation, as obtained from Dr. Mirus, was a light pinkish coloured emulsion, and the contents of one tin, weighing 52½ drachms, yielded on evaporation to dryness a residue which weighed 12½ drachms. Two hundred and forty grains of this dry solid were thoroughly exhausted by repeated washings with tepid water, the residue dried and the watery solution evaporated to dryness. The dried soluble extractive weighed 79·5 grains, whilst the insoluble portion weighed 157·5 grains.

I then boiled finely chopped lean fresh meat (a portion of which, when dried, gave 26 per cent. of residue) with five times its weight of water, in a Pappin's digester, for thirty hours; filtered, well washed, and dried the residue, and evaporated the solution with the washings also to dryness. From 1000 grains of meat were obtained 82·2 grains dry soluble extract, and 182·0 grains insoluble residue.

BY COMPARISON,

Meat digested with water only in a Pappin's digester gave for 1000 parts:—		The Leube Rosenthal'sche preparation gave for 1000 parts:—	
Soluble Extract	88·2	Soluble Extract	76·0
Insoluble Residue	182·0	Insoluble Residue	153·0
Water	729·8	Water	771·0
	1000·0		1000·0

or, comparing the relative proportion of soluble to insoluble, in the dried matter,

Meat simply digested in a Pappin's digester gave for 100 parts:—		The Leube Rosenthal'sche preparation gave for 100 parts:—	
Soluble	32·7	Soluble	33·2
Insoluble	67·3	Insoluble	66·8
	100·0		100·0

a difference so slight as to warrant a belief that the solution of other matters than those soluble in cold water was altogether due to the stewing under pressure, and in no way affected by the dilute acid used in preparing the Leube Rosenthal product; and that this preparation, as might have been anticipated, is meat, the fibrine of which is merely in a very finely divided condition, and not changed into peptone. The term applied to it of "flesh solution," although convenient, is evidently, therefore, altogether a misnomer.

Von Wittich states that dilute acids alone will convert fibrine into peptone, but according to his experiments, it required a digestion of twenty-four hours' duration, at a temperature from 86° to 104° Fah., to change only 1 per cent. of the fibrine into peptone, and although it remains to be shown that by a prolonged action the whole of the remaining fibrine (99 per cent.) would be converted, and without undergoing further change, yet anyone conversant with the treatment of meat needs not be told that even were it so, and at the rate previously indicated, such a method would be totally inapplicable for any considerable quantity.

It is not, in my opinion, assuming too much to state that at present no other method is known by which the fibrine of flesh can be changed to a soluble condition and the whole meat rendered soluble and acceptable as an article of diet, than that by means of pepsin and dilute acid, as in the case of the preparation known as "fluid meat."

The authors of the Rosenthal'sche Fleisch solution, so far as I am aware, do not claim that they convert the fibrine into peptone, and any mention of "fluid meat" would be uncalled for here, were it not that the two preparations have been mistaken as identical, and that it has been assumed that they both consist of peptones.

It has been clearly shown that the German preparation does not consist of peptone, and that it is principally insoluble material, in no respects possessing the properties of "fluid meat." To this latter substance the late Baron Liebig unconsciously alluded when he wrote:—"Were it possible to furnish the market at a reasonable price with a preparation of meat containing in itself the albuminous (*i.e.*, fibrine and albumen) together with the extractive principles, such a preparation would have to be preferred to the *Extractum carnis*, for it would contain all the nutrient constituents of meat." Contrary to Baron Liebig's doubt that "there is no prospect of this being realized," it has been not only accomplished—by an artificial process closely allied to the natural one—but a long-continued employment of the so changed meat in many difficult and most trying circumstances has proved that it does contribute all the nourishment of ordinary meat, and under conditions where this would not be available. Cases are now recorded of impaired and even suspended power of digestion, both from natural and accidental causes, in which "fluid meat" has not only sustained life during long periods, but enabled a restoration of the digestive functions to become effected.

HERB CULTIVATION AT MITCHAM.*

Mitcham has long been celebrated for its herb fields, from which the London herbalists derive their mint, sage, liquorice, and similar herbs. Of these, as a rule, distillations are made by the growers, and they are disposed of in a semi-refined condition, or the herbs themselves are brought into market as soon as they are harvested.

Chamomile.—To this several acres are devoted, the double-flowered kind being preferred on account of the weight of the produce; but both single and double sorts are grown. In March, old and somewhat "spent" plantations are broken up and the plants divided into good-rooted slips, which are planted in well-prepared ground in rows 2½ feet apart, and 2 feet asunder in the rows. A common practice, however, is to plant as thick again as this, and to thin out the plants afterwards to the distances just named. The plantations are intercropped with lettuces in spring. As soon as the blooms begin to expand, they are fit for gathering, and from that time, as long as they yield sufficiently to pay, the flowers are gathered several times in a season by women, who are either paid a regular day's wage, or a penny, or thereabouts, per pound for picking.

Lavender.—This is extensively cultivated at Mitcham, both farmers and cottagers bestowing special attention on it; and this district presents a lovely sight in the last fortnight in July, when the different fields of it are in full bloom, the air for miles around being loaded with its fragrance. Lavender is increased by means of rooted slips, planted out, in rows about 18 inches apart and half that distance asunder, in March or April. Sometimes the sets are planted as wide in the row as the drills are apart. For the first year the produce amounts to but little; and, therefore, parsley or lettuce is planted between the rows. As soon as the plants have grown sufficiently to become crowded, every alternate row, and also every alternate plant in the rows left, are lifted—say in spring—and transplanted into another field, so as to form a new plantation. Thus the plants stand 3 feet apart each way, or 3 feet one way and 18 inches the other. Coleworts, lettuces, or other early and quickly matured crops are raised amongst the lavender in the early part of the year; but after June, all such catch-crops are removed. The flowers are usually harvested in the first fortnight of August.

Liquorice.—This was once largely grown at Mitcham, but, although it is still grown in considerable quantities, it is not now so extensively cultivated there as formerly, on account of the cost attending its culture. It entirely occupies the ground for three years, and during that time requires great attention in the way of cleaning, besides the ultimate cost of trenching out the roots, or rather, underground stems. The ground being deep, is heavily manured in autumn or winter, when it is trenched and laid up in ridges, in a rough state, till spring. It is then levelled, marked off in drills about 2 or 3 feet apart, and some 3 or 4 inches deep, and in these the sets are planted in March. The sets consist of finger-length pieces of the old root-stems, each containing an eye or two. During the first year the ground is usually intercropped, as is also the case in the earlier portion of the second year; but after the middle of the second summer, and throughout the whole of the third year, the liquorice requires all the room. When the stems are matured in the autumn of each year, they are cut over close to the ground, and if time can then be spared, the soil between the rows is forked over, some well-decayed manure being occasionally worked into it at the same time. The lifting of the crop, which usually takes place in the end of the third season, is a difficult operation, involving much labour. A deep trench is cast out, lengthways, alongside the first row, and by means of forks, pulling-ropes being even sometimes employed, the root-stems are extracted. In this manner the whole of the rows are treated, until all are successively lifted. The roots may then be stored in sand or pits, like beets, carrots, or potatoes. Growers of liquorice do not always harvest the crop; but sometimes sell it as it stands in the field.

Mint.—Both spearmint and peppermint are largely grown at Mitcham, particularly the latter; indeed this crop ranks second in importance only to lavender. It is first planted in rows 13 inches apart each way, and in the end of the next two seasons it is ploughed in. The plantations are kept free from weeds during the summer by means of hoes; and about the end of the first week, or during the second week of August, is the usual time for cutting mint for distillation. In the Fulham fields, and in other districts in which market-gardening is carried on, mint is largely grown for sale in a green state. For this purpose the dampest piece of ground is selected for its culture, if it is to be a permanent plantation, but it will grow in almost any soil. It is planted in rows a foot apart, and the ground is intercropped the first year, but afterwards it runs through the soil in such a way that it becomes a complete mass of under-grown stems and roots. It is cut and bunched for market as required, the greatest demand for it being during the pea season. It is also forced in large quantities. I have seen a range of 43 light frames filled with mint alone. These beds are made up in December or January, when the ground they occupy is excavated to a depth of 20 inches, and filled in with fermenting manure packed firmly. A few inches deep of soil are then added, and in this the mint roots are thickly planted. Linings of manure are placed round the frames, the sashes during the night and in cold days being covered with it.

Poppies.—Of the white kind several acres are grown. They are sown in rows in spring, some 20 or 24 inches apart, and require no further care, beyond a little thinning and cleaning, till August, when their seeds ripen.

Sage.—This forms an important crop, which, under favourable circumstances, is pretty remunerative; the stalks being cut over, bunched, and sent to market at once. New plantations are formed with rooted slips, obtained by dividing the old plants; they are inserted, late in spring, in rows 1 or 2 feet apart, and about a foot asunder in the row. During the first season parsley or lettuces form an inter-crop, which also occupies the ground during the earlier part of the succeeding ones. Except hoeing and cleaning, the plantations need no care so long as they continue in a thriving condition; and, when the lines get broken, and blanks and sickly plants occur, the plantation is broken up. Both the reddish and green-leaved kinds are cultivated.

Squirting Cucumbers.—These are raised in frames, like vegetable marrows, and are planted out, about the end of May, in rows some 4 or 6 feet apart, and 4 feet asunder in the row. They flower and fruit at the same time, and the fruits are gathered before they are ripe, otherwise a mere touch would burst them.

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SOCIETY'S EXAMINATIONS.

WE have recently received so many inquiries in reference to the new regulations which are to come into force in future examinations that we think it desirable to regard these inquiries as indicative of a general desire for information on this subject, and to give here a detailed explanation of the changes that will have to be taken into account and provided for by future candidates.

First, as regards the Minor Examination, which still remains the portal to the practice of pharmacy as a principal, there will be no more examinations under exactly the same conditions as heretofore. On and after the first of October next, when the examinations will be resumed, certain alterations will be made, and the chief one among these is the requisition of practical knowledge of the chemical processes by which medicinal agents are produced. It will also be demanded that candidates shall be able practically to determine, by means of tests, the presence of certain substances in solutions given them for that purpose, and to explain the reactions which take place in the tests they apply in each case. In short, they will be required to give evidence of a fair knowledge of qualitative analytical chemistry. That this requirement is consistent with existing conditions will, we think, be obvious from the fact that there is a very general disposition on the part of pharmacists to undertake the duties of public analysts. That the general nature of the pharmacist's avocations are quite in harmony with the performance of such duties will, we think, be admitted without argument, and we have long since urged that there is no class of the community more fitted for holding this office. If that be the case, it is important that some means should be adopted of ensuring competence on the part of pharmacists qualified legally by examination, and the introduction of the new feature of requiring evidence of practical acquaintance with chemical analysis is, we think, to be regarded as a wise step in pursuance of the old policy of the Society, to raise the character of the pharmacist's business, and improve his position.

We are aware that there are some who do not share these opinions, that among those who aspire to the qualification for carrying on business on their own account, there are some who think it a hardship that they are required to prove they possess the knowledge which is essential for the proper performance of their duties, while, on the other hand, there are, among those engaged in business as principals, some who deprecate the introduction of the changes here referred to, on the ground that they render it difficult to obtain assistants.

As regards the objections of the former class, they probably demand no great consideration; but those of the latter class are more serious, and it will be well for all who have the interest of pharmacy at heart to endeavour to counteract this (as we think) mistaken opposition to progress. If we seek to ascertain how it is that increased stringency of the examinations can operate in restricting the supply of assistants and apprentices, we fail altogether to find any justification of the hostility with which the new examination regulations are regarded by some. For it must be remembered that the Minor Examination is not one necessary for the performance of the duties of an assistant. It is in order to commence business on their own account that candidates seek to pass the Minor. How, then, can the stringency of this examination limit the supply of assistants? Is it not more likely that it would augment that supply? Would not young men, desirous of passing the Minor with a view to commencing business for themselves, be the more readily induced by the stringency of that examination to engage themselves as assistants, where they would have opportunities of acquiring the knowledge requisite for passing it with credit?

Besides the main feature of alteration to which we have referred as having been introduced in the Minor Examination, there is also an addition to what has hitherto been demanded in regard to prescriptions. The candidate must now show that he has a general knowledge of Posology, that he is able to detect errors and discover unusual doses, as well as to render, in good Latin, ordinary prescriptions, written in English. He must also possess a practical knowledge of the processes by which the extracts, tinctures, etc., of the Pharmacopœia are made, as well as a knowledge of the principles involved in those processes.

These are the chief features of alteration which will come at once into force as regards the Minor Examination. On and after the 1st of January, 1875, however, there will be a further demand made upon candidates, inasmuch as they will, from that time, have to produce certificates of having attained the full age of twenty-one years. Then, again, on and after the 1st January, 1877, each candidate must, in addition to other requirements, produce certificates to the effect that he has for three years been registered and employed as an apprentice or student, or has otherwise been practically engaged for three years in the translation and dispensing of prescriptions.

From the time when this latter regulation was adopted by the Council up to the time when it is to come into force, three years will have elapsed, so that any one who has failed to comply with this condition cannot have any reason to complain of hardship, except such as may arise from his own negligence.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, September 2nd, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

Present—Messrs. Betty, Greenish, Hampson, Owen, Radley, Rimmington, Robbins, and Sutton.

The minutes of the last meeting were read and confirmed.

Mr. BETTY suggested that the Committee recently appointed to consider the educational arrangements of the School in Bloomsbury Square should have the scope of their inquiry somewhat enlarged, so as to include the question of all pharmaceutical education in any way subsidized by the Society, whether in London or in the provinces.

Mr. HAMPSON thought if the question of the education in London were satisfactorily settled, the rest would arrange itself.

After some conversation it was considered best to make no alteration in the terms appointing the Committee, but the name of Mr. Mackay was added to the list of members.

The name of a former member who had neglected to pay his subscription in due time, was restored on payment of the subscription for the current year and a fine.

ELECTIONS.

MEMBERS.

Chemists and Druggists.

The following registered Chemists and Druggists were elected Members of the Society:—

Blackhurst, William Swarbrick...Kirkham.
Cox, Samuel................................Maidstone.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society:—

Minor.

Chesterton, William Peter ......Birmingham.
Churchman, James ....London.
Hindson, James Alfred ....Old Brompton.

Modified.

Hancorn, John Thomas ....Torquay.
Young, John Matthew ....Girvan.

The following having passed the Minor Examination were elected "Associates" of the Society:—

Amery, John ....Taunton.
Broadbent, Sidney ....Greenfield-in-Saddleworth.
Cumine, Rupert Henry ....Kingston-on-Thames.
Cuttle, Arthur Edward ....Scarborough.
Hodgkinson, Peter James ......Congleton.
Kimber, Benjamin Tindall ......Southampton.
Midgley, James Herbert ....Edinburgh.
Newitt, Herbert Henry ....Bicester.
Oakes, Henry.........................Pickering.
Partington, John James ....Macclesfield.
Robbie, William ....Aberdeen.
Stedman, Harry Bernard.........Bayswater.
Stiling, John Edward ....Exeter.
Wells, John ....Sleaford.
Wigginton, Alfred ....Islington.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Batchelor, Alfred Ernest.........Fareham.
Beacock, Joseph Henry ....Barton-on-Humber.
Blyth, William Graves ....Goole.
Cowgill, Benjamin Rangdale ...Bingley.
Dester, Dester .... Warton.
Hayes, Frank ....Gainsborough.
Howe, Oliver George ....Stony Stratford.
Lodge, George Henry ....Rotherham.
McGuffog, Robert ....Dumfries.
McKenzie, Thomas Daniel ......St. Helen's.
Parkinson, Charles ....Preston.
Searle, Samuel ....Newton Abbott.
Thomas, Henry James............Llandilo.
Whittles, John Dencer............Birmingham.

The name of Robert Dixon, of 41, Upper Brook Street, Derby, was restored to the Register of Chemists and Druggists.

FINANCE.

The report of this Committee was received and adopted, and various accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee was read. It recommended the grant of £20 to a former member of the Society who had suffered from a severe accident; £5 to one of the candidates for an annuity; and £15 to a former member at Dover. Several applications were deferred for further inquiries.

The SECRETARY said these applications to the Benevolent Fund were of great importance, and he thought it would be well if special meetings of the Committee were called to consider them.

Mr. GREENISH remarked that wherever possible it was very desirable that the applicant should attend the Committee personally.

Mr. ROBBINS said this was generally done in other benevolent societies in London. It was also desirable that some one should make inquiries into these cases and report to the Committee.

Mr. SUTTON observed that this was always done in country cases.

Mr. HAMPSON said the Committee could not be too particular in their inquiries in all these cases.

The PRESIDENT believed that generally speaking some one of known position recommended the applicants from personal knowledge.

Mr. GREENISH said it was sometimes found on pressing further inquiries that the answers were not so satisfactory as might have been expected from the first communications.

The report was adopted, and the recommendations ordered to be carried out.

HOUSE COMMITTEE.

This Committee reported that in doing some of the repairs which had recently been directed it was found that one of the chimneys was in a very dangerous condition and required to be rebuilt. An estimate had been obtained for the necessary work, which was now submitted. The Surveyor now attended the Council, and after hearing his opinion upon the subject, the report was received, and the necessary work ordered to be done at once.

A PHARMACY ACT FOR IRELAND.

The SECRETARY submitted to the Council communications from the Secretary of the Irish Chemists' and Druggists' Association, on the subject of extending the provisions of the Pharmacy Act to Ireland.

The PRESIDENT said this correspondence referred to a very important question, and he would suggest that its consideration be deferred to the next meeting of Council, particularly as the attendance was so limited on the present occasion. This was unanimously agreed to.

THE ST. PETERSBURGH CONFERENCE.

Mr. GREENISH stated that his colleague, Mr. Sutton, and himself were preparing a full report of the proceedings at this Conference, but it was not quite finished, and they therefore thought it better not to present it incomplete, but to defer it until the next meeting.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page 176.*)

The Application of Oleic Acid in Pharmacy.

BY C. R. C. TICHBORNE, PH.D., F.C.S., ETC.

It is extraordinary to what an extent we are the slaves of habit, and how frequently the obvious royal roads to the goal are deserted to follow a beaten but circuitous tract.

The alkaline salts of oleic acid (soaps) used in pharmacy form a valuable and important class of preparations, and yet they are all procured by circuitous routes, at an extraordinary expenditure of time and money, but with an unsatisfactory result. Once upon a time (and not very long back) oleic acid was a chemical curiosity, valueless in the arts, and very little known, except to the scientific chemist. Now this is all past, and the acid is manufactured of considerable purity by the ton, and at a price before which no fats or oils suitable for pharmaceutical work could compete. Why this substance has not been made available in pharmacy is not so curious as might appear at first sight. It will be found from the experiments detailed that the so-called oleic acid of commerce presents some slight difficulties as regards its manipulation.

The first and only suggestion of importance that I am aware of for the use of oleic acid in pharmacy was Professor Attfield's paper upon the solution of the alkaloids in this acid, to be used in conjunction with cod-liver oil. These preparations have now gone out of use, and therefore a most valuable suggestion has fallen through. There cannot be two questions about the elegance and practicability of this method, and wherever a powerful alkaloid, such as aconitia in Ung. Aconitiæ is to be mixed with a fatty body, we should use the oleate. We thus obtain a solution in the fats, not a mechanical mixture.

There has been a second application of oleic acid, oleate of mercury; but from its appearance and other causes I do not think it will ever be much used.

I have had a series of experiments made with the view of practically introducing this so-called oleic acid, or the liquid fatty acid of commerce into the preparations where soap is introduced.

Many of the experiments so made, seemed at first to be unpromising; but as they were theoretically correct, they were persevered in until many excellent formulæ, as regards the appearance and general results, were produced.

In speaking of oleic acid as found in commerce, Messrs. Price and Co. gave me the following information which, I think, will be of sufficient interest to note here. There are one or two qualities in commerce, the best of which is known as pale cloth oil. The brown German oleic acid when bought by the ton is extremely cheap, but is much inferior in quality to the oil known under the above name or brand. It is, of course, a kind of by-product, procured by the splitting up of palm or other oils by superheated steam into glycerine and the fatty acids. The stearic acid and hard fatty acids are used in the manufacture of candles and for other purposes, whilst the fluid portion is pressed out, and is the article known as oleic acid of commerce. Although the oleates are perfectly harmless providing the base is so, the acid itself would appear to be therapeutically a poison. Thus, Messrs. Price and Co. point out that, although rats and mice are passionately fond of all neutral fats and oils, they carefully avoid oleic acid. It would be useful to determine how far this is the fact. Externally it seems to produce an irritability of the skin when used unneutralized.

It is my intention, on this occasion, to consider its application to the liniments, a class of preparations in which the oleates form an important part.

The soaps of the Pharmacopœia are as follow:—1. The hard soap, "Castile soap," supposed to be a hard soda soap made from olive oil, but very uncertain in its composition.

2. Soft soap.—An olive oil soap made with potash.

3. Animal soap, "curd soap," supposed to be a soda soap made with tallow, equally uncertain in its composition as the Castile soap.

The oleates, or soaps with which we have to do in this paper, I may as well describe in a concise manner, but it is necessary to bear in mind that this description applies to the oleic acid products as made from the commercial acid.

If we consider oleic acid as a bibasic acid the formulæ of the soaps will be $C_{36}H_{66}M''O_4$. The oleates differ from the palmitates and stearates in being perfectly soluble in alcohol—a most important point when considered in connection with liniments. The neutral oleate of ammonium is a very pectrous salt, capable of a very considerable amount of dilution before it gains a liquid consistency.

The oleate of sodium is practically insoluble in the cold, only a small proportion remaining dissolved, and the mass of it being deposited in a granular condition, or as a curd. It dissolves in weak spirit. The oleate of potassium is very soluble in cold water and pectizes easily.

I might enlarge upon this portion of my subject, but prefer to give a general outline of the practical application of this acid to the production of the liniments.

I may mention that the oleic acid, called "pale cloth oil," is admirably adapted for the production of liniments, but the acid does not improve by age, and very old samples do not pectize so easily as new ones; I may mention that the colour may be improved by digesting with pure animal charcoal.

Linimentum Ammoniæ.—This preparation, the old "oil and hartshorn," is, in the first stage of its existence, an emulsion of olive oil in the presence of an excess of ammonia. By degrees the oil is slowly saponified until we get nothing but a semi-solid ammonium soap.

I should prefer to make this liniment in the following manner:—

Take of—

Oleic Acid	℥ss.
Water	℥ij.
Strong Solution of Ammonia	ʒiss.

Mix the water and oleic acid, and add the solution of ammonia gradually, but with agitation.

The result will be a liniment having a definite and unchangeable composition.

Lin. Potassii Iodidi c. Sapone.—This preparation in the Pharmacopœia is a solution of iodide of potassium with an insoluble oleate of sodium and glycerine, etc. Nothing can be more unmanageable than this formula, and yet it is a useful addition to the medical practitioner's list. It is a powerful stimulating liniment, which can be used with ladies where tincture of iodine is not desirable. It has not come into more general use simply from the great uncertainty and ugly appearance which this curds-and-whey-like preparation presents. I propose to make it in the following manner:—

Take of—

Oleic Acid	6 ounces.
Carbonate of Potassium	2 "
Iodide of Potassium	7½ "
Glycerine	5 "
Oil of Lemon	5 drachms.
Water	2½ pints.
Solution of Potash, a sufficient quantity.	

Dissolve the carbonate of potassium with heat in 10 ounces of the water, and add the oleic acid, and after the effervescence has subsided, add the iodide of potassium, glycerine and oil of lemon mixed together, and then a sufficient quantity of the solution of potash to make it the requisite consistency, which it does by virtue of its power of producing a pectizing oleate.

Linimentum Saponis, B.P.—This has been a much-abused formula, and deservedly so. In this liniment a soda soap acts an important part, and as the fatty acids which are found in the ordinary soap of commerce are only partially soluble in spirits of wine, it only contains a minimum of the soap used. It is supposed to be a fluid liniment, and not a jelly like the original opodeldoc, of which it is a copy. If we obey the directions as regards temperature in making this liniment by maceration for seven days, we get a partial solution of the soap, and the stearates and other fatty salts are left, amounting to a large percentage.

My formula would be as follows:—

Take of—

Oleic Acid	8 ounces.
Carbonate of Sodium	4 ,,
Camphor	5 ,,
Oil of Rosemary	12 drachms.
Rectified Spirit	3 pints 12 ounces.
Water	8 ,,

Dissolve the carbonate of sodium in the water with aid of heat, and add gradually the oleic acid; when the effervescence has subsided, add the oil of rosemary and camphor dissolved in the spirit and filter if necessary.

The advantages are that we have a formula that contains all the soap in solution and in a perfectly neutral state, for if any excess of carbonate of sodium has been used, it is precipitated by the spirit. We are also enabled to make the liniment in as many minutes as it required days by the old process.

There are certain liniments which may be viewed as emulsions. Linimentum Terebinthinæ is typical of their preparation. Oleic acid behaves beautifully in such liniments.

Linimentum Terebinthinæ.—Take of—

Oleic Acid	1 ounce.
Oil of Turpentine	16 ,,
Camphor	1 ,,
Solution of Potash	q. s. ,,

The camphor and oleic acids are dissolved in the turpentine, and the liquor of potash is added gradually with constant agitation, until the whole emulsifies.

I do not pretend for a moment that these formulæ are the best that can be devised in connection with the use of oleic acid; but I do say, and have no hesitation in saying, that the days of the old formulæ are numbered, and that any one who makes the saponaceous liniments from oleic acid will never return to the soaps. I may, in conclusion, mention that no objection can be raised to oleic acid on the score of cost, as it will easily compete with the soaps in that respect. There are other applications of oleic acid which I must reserve to a future occasion. I have preferred to restrict my remarks to one class of medicaments.

The PRESIDENT: This is my first introduction to Professor Tichborne, but I hope we shall often have the pleasure of seeing him here again. His paper contains a great deal of interesting matter which well deserves the attention of the next Pharmacopœia Committee, whether that committee is composed partly of pharmacists and partly of medical men, or wholly of medical men. The subject is certainly worthy of further experiments; and I have no doubt many gentlemen who read the paper will further investigate the subject. I have now to ask you to pass a vote of thanks to Professor Tichborne.

The vote of thanks was passed unanimously.

Mr. FRAZER: I may state, as showing that Professor Attfield's suggestion has not altogether fallen to the ground, that our principal oculist in Glasgow had considerable difficulty in the application of aconite, and applied to myself to get a solvent for it. I applied to Mr. Morson, and he advised me to have it dissolved in oleic acid, and now, for a considerable time, it has been in daily use for this purpose by Professor Reid, lecturer on diseases of the eye in the University of Glasgow.

Professor ATTFIELD: I must say that I cannot altogether claim originality in suggesting the dissolving of matters in oleic acid, because when some seven or eight years ago the method of dissolving alkaloids in oils was published, I had brought to my notice the fact that some one had fifteen or twenty years ago, in the land of Lavoisier, stated that alkaloids could be dissolved in fatty acids.

Mr. SCHACHT: There is one observation I should like to make with reference to this paper, namely, that although one might see the desirability of employing oleic acid in the place of olive oil in the manufacture of soap, I could not help thinking it would be desirable, in most cases at least, that a definite compound should be first of all prepared rather than attempt to extemporize this formula at the moment of use, because the chances are, we should not get so perfectly neutral a preparation as would in many cases be desirable. But I wish to speak of that peculiar, and according to my experience very useful, preparation, the liniment of iodide of potassium and soap, which I believe owes its paternity to Messrs. Smith, of Cheltenham. A very satisfactory result was obtained by the use of one particular kind of soap—one which, I believe, contains very little oleate of soda, but a large proportion of stearate of soda, the curd soap of Messrs. Benbow. When that is used, you certainly do get a charming preparation, one which resembles clotted cream in consistency more than anything else. It is very constant, and maintains its consistency very perfectly for a great length of time, and you can produce the same article invariably by using the same materials. Of course, it is an open question whether much effect is produced by the external application of iodine in any form; if it is to be applied, however, this is a very elegant preparation. But if any one attempts to make it with oleate of soda, they will get a wretched result, neither solid nor liquid.

The PRESIDENT: Are you quite sure that the soap you refer to is a stearate soap, and that it contains no cocoa-nut oil? Because the cocoa-nut oil soaps have this property, that they can be dissolved in saline solutions, whereas stearate soaps cannot.

Mr. SCHACHT: I know that the oleic soap produces a very bad result, but I cannot speak absolutely with regard to cocoa-nut oil.

Mr. MARTINDALE: As oleic acid mixes well with alcohol, I think it might be suggested that it should be used in belladonna and aconite liniments in place of the camphor, as it would aid their absorption, and make them more compatible with liniments generally. It mixes with them, but not quite so well unless it be pure, and there is great difficulty in getting it of sufficient purity. With regard to the statement that all oxides dissolve in it, I have tried oxide of iron, and cannot get it dissolved in any way. It would be a great advantage if you could get oxide of iron dissolved in oleic acid, in order to mix with cod-liver oil.

The PRESIDENT: According to my experience the best way of dissolving peroxide of mercury in oil is to rub up in a warm mortar equivalent quantities of bichloride of mercury and powdered olive oil soap, and afterwards add a little boiling water to produce reaction and form the oleate. I have thus got a nearly white mercurial plaster that dissolved readily in hot oil, and kept well without turning black. By heating peroxide of mercury with the oleic acid I employed, I obtained a plaster that speedily became slate-coloured from reduction.

Mr. UMNEY: The specimen of oleic acid placed on the table by Professor Tichborne is far superior to any we see in trade in England at the present time. I believe many specimens would be better described as oxy-oleic acid; at any rate, that with which one meets in many shades darker than the specimen before us, and might be described as of a deep sherry colour.

Professor ATTFIELD: In reply to Mr. Martindale, I may say that oxide of iron is very slightly soluble in oleic acid; I dare say insufficiently so for any preparation to be used in pharmacy. With regard to varieties in the quality of oleic acid, I have seen some samples used in large quantities quite as good as that on the table; though, no doubt, the bulk of that met with in the trade is much darker. Oleic acid is now produced on an enormous scale, and is extensively used by clothworkers. As is well known, oils and fats of many kinds, which were formerly thrown away, being so impure as to be almost useless, are now recovered, as the phrase goes, and thus an immense amount of oleic acid is thrown into the trade. The better varieties, of course, command higher prices than the darker, but still there is a large quantity of light-coloured oleic acid to be had at a fairly reasonable rate, far more than is ever likely to be used in pharmacy.

Mr. RIMMINGTON thought the smell would be objectionable. The samples now shown had a peculiar smell, and so had every specimen he had seen, in most of them it being much more marked. It was a kind of burnt smell.

Dr. DE VRIJ: I should certainly object to the introduction of oleic acid into pharmacy, for of all the fatty acids I know none which varies so much in its composition. Everyone who has ever experimented with oleic acid knows that it rapidly absorbs oxygen from the air, and therefore it is very difficult to get it pure, so that if you use oleic acid you will have to prepare it yourself. I certainly should not advise its introduction.

Mr. HANBURY: I think it is really very questionable whether the by-product of a German manufacturer, which can be had at a few shillings the cwt., is, after all, such a very admirable substitute for the old-fashioned olive oil which we have been accustomed to use. No doubt, it is right to take advantage of these chemical improvements, but we may, perhaps, be in some danger of preferring cheapness to goodness.

Professor ATTFIELD: The oleic acid is very largely produced in England.

Professor REDWOOD: I may be allowed to express my thanks to the Professor for bringing this subject forward, and for having undertaken so many experiments in reference to it. You are probably aware that some time ago, and on more than one occasion, I have suggested to this Society the desirability of investigating the whole subject of the liniments used in pharmacy, for I consider those of the Pharmacopœia to be at the present time in a most unsatisfactory position. We are very much in want of some general principle upon which to proceed in the preparation of the liniments, and in devising formulæ for them, and here we have a suggestion certainly which may prove useful, and though, as has been stated, the formulæ put forward are, perhaps, not yet perfect, further investigation may lead to very valuable results. I may mention, in particular, the liniment of turpentine with acetic acid—a preparation containing ingredients which separate immediately, and which cannot be kept united. I have made several experiments with a view to getting a more homogeneous liniment as a substitute; in fact, the whole of them require revision, and I hope some day to see some general principle acted upon—some common menstruum adopted, which shall serve as a medium for the application of the more active constituents, and I look rather hopefully to the use of oleic acid.

Professor TICHBORNE: In connection with the objections which have been made, I will first of all make a remark in connection with Linimentum potassii iodidi cum sapone, and the recommendation to make it of curd soap. We have been discussing the merits of the formulæ contained in the Pharmacopœia, and though this liniment is there mentioned, unfortunately curd soap is not. It has lately been introduced into the Addendum, but of course did not exist at the time the formula for that liniment was given, so that it was evidently intended that it should be made from a soap which was an oleate of soda. While upon this subject I may dispose of the question of the purity of oleic acid, more particularly as one gentleman has objected to it as being indefinite, and thus unfit to be used as a substitute for soap. I must ask him did he ever go over a soap-works, and see the curious things that are sometimes put in the vats? Because, if he had, he would find that soaps are much more indefinite than commercial oleic acid. The sample on the table is a commercial sample, Messrs. Price's best quality; they have two, I believe. It is no pet specimen, it is just as any one would get it who ordered the best quality of oleic acid from that house. It is a very old sample, and was simply taken from a cask about half-an-hour before I left Dublin. It is, no doubt, true that, chemically speaking, a change takes place in oleic acid, and that it becomes chemically indefinite, and we have yet a great deal to learn on this subject. But it should be borne in mind I made a reservation, and said I was speaking of the properties of oleates as derived from commercial oleic acid. In connection with liniments, all we have to do with is the peculiar conditions they take as regards their consistence; and I think, on repeating my experiments, it will be found that, when made with oleic acid, it is quite immaterial whether they are one month or twelve months old. Of course this is an important point, but after all it is a question of consistency. There are, I know, some very inferior specimens of German manufacture in the market, but they are introduced for rough work, and no one would buy them for the purpose of making liniments any more than they would common soft soap made from fish oil. I do not think the smell is any practical objection. If you get oleic acid of inferior quality, no doubt it will have a strong smell, and you will find it varies in this respect very much, but I have no doubt, if there is any demand for it in pharmacy, that this little difficulty will be got over. I do not believe the smell has any connection with the oleic acid itself, as is shown by the fact that you find a different smell in different samples; but if you think for a moment that there is not one of these liniments on the table that does not contain a very strongly odoriferous substance, I think one might defy the most sensitive nose to detect the smell of oleic acid in any one of them.

Mr. WILLIAMS: I can well believe Professor Tichborne that the sample of oleic acid from Messrs. Price's he has shown us is an old one, for my experience is that you cannot get anything like it now. I have had a great deal to do with the preparation of oleate of mercury, and I find that oleic acid has become very bad of late, so that there is great difficulty in preparing an oleate that will keep, and be what it ought to be as a pharmaceutical preparation. I have tried many experiments to purify this acid, but I have not yet succeeded to my satisfaction, and shall be glad if any chemist or pharmacist will turn his attention to the subject. I believe there is a great future for this article, and that it must come largely into use, but certainly the commercial samples now in the market are not good enough for pharmaceutical purposes.

A MODIFICATION OF LIEBIG'S VOLUMETRIC PROCESS FOR THE ESTIMATION OF PHOSPHORIC ACID.

BY W. W. STODDART, F.C.S., ETC.

A short time ago, when examining some of the Somersetshire lias quarries, the author noticed the phosphoric appearance of some of the strata, but was too far away from laboratory assistance to prove the fact. In this emergency he applied to a country pharmacist, hoping to find some solution of iron that would enable him to roughly attempt the process devised by Liebig for estimating phosphoric acid. However, the only thing obtainable was the ordinary tincture. A trial, nevertheless, was made by means of that preparation, a little liquor ammoniæ and vinegar, with a small bit of ferrocyanide of potassium, and two long phials in lieu of a burette. The result, of course, only just enabled the author to choose for home examination those specimens that contained the largest percentage of phosphoric acid.

This little incident, after returning home, led to more extended experiments, which ended in the devising of what is believed to be an easy method, as well as a correct one, of determining the value of phosphates in manures and minerals.

This is often required by the agriculturist, geologist, and mineralogist, when both time and facility are of great moment. The magnesium method requires a considerable time for its completion, as well as delicate manipulation to avoid loss.

The uranium method, so well described by Mr. Sutton in his valuable work on volumetric analysis, requires so expensive and special a salt, that it is seldom found outside the well-appointed laboratory, where it is usually employed as extremely reliable and delicate.

It is to meet such cases as those mentioned that the method described in the following notes was devised:—

Long since it has been known that the solution of a soluble phosphate, mixed with an alkaline acetate and free acetic acid, is precipitated entirely by ferric chloride. Taking advantage of this reaction, Liebig suggested a volumetric process, and using ferrocyanide of potassium as an indicator. This is not so accurate a method as that with the uranium salt, and in practice is very troublesome from the decomposition of the precipitated phosphate into a more basic condition, and also from the fact that the precipitate itself will produce a blue colour with the indicator.

The present modification is intended to obviate this difficulty by substituting the sulphocyanide of potassium for the ferrocyanide. The determination of the phosphoric acid is thereby rendered as easy and correct as that of the chlorides by nitrate of silver.

The following solutions are recommended:—

No. 1.

Perchloride of Iron .	240 grains (or 24 grammes.)
Water	10,000 grains (1 litre.)

If not quite dissolved, add a few drops of hydrochloric acid. The liq. ferri perchlor., B.P., answers equally well.

No. 2.

Sodic Phosphate .	504·2 grains (or 50·42 grammes.)
Water	10,000 grains (1 litre.)

One c.c. of this solution = ·01 gramme or one ten-grain division of the burette = ·1 grain of phosphoric anhydride. This solution is of course for the purpose of ascertaining the value of No. 1.

No. 3.

Sodic Acetate . . .	2¼ ounces (or 100 grammes.)
Glacial Acetic Acid .	2¼ ounces (or 100 grammes.)
Water	10,000 grains (1 litre.)

The following is the mode of procedure in performing the analysis:—

Dissolve five grains of the sample in dilute hydrochloric acid, and to the filtered solution add about eight or ten drops of ammonia, and redissolve the precipitate with a little acetic acid. Then add one drachm of No. 3 and a few drops of the solution of sulphocyanide of potassium and make up to about an ounce with distilled water. Now run in the No. 1, previously titrated, till the creamy colour begins to assume a reddish tint. The reaction is then complete, and the volume of iron used indicates the proportion of phosphoric acid precipitated. To find out very exactly the moment when sufficient iron has been employed, and begins to appear free in the liquid, place on a white slab a filtered drop with one of the sulphocyanide, when the slightest reddish-brown tint will show the time of saturation or when sufficient iron has been taken. It is always better to use a very dilute solution of the phosphate under examination, or the red tint will be hidden by the precipitate.

The sulphocyanide of potassium may be readily made by boiling together for ten minutes, 120 grains each of common fused cyanide of potassium and sublimed sulphur in an ounce and a half of water.

The following comparative trials proves the constancy and accuracy of the sulphocyanide process, the result being calculated as tricalcic phosphate:—

	Magnesian process.	Uranium process.	Sulphocyanide process.
1. Superphosphate . .	46·147	46·171	46·174
2. ditto . .	39·165	39·169	36·168
3. Blood Manure . .	32·459	32·462	32·465
4. Liassic Coprolite .	24·163	24·201	24·200
5. Guano	26·440	26·452	26·454
6. Ditto	32·314	32·320	32·326

The PRESIDENT said the use of sulphocyanide as an indicator in place of ferrocyanide seemed a manifest improvement in the process.

NOTES ON A NEW LACTOMETER.

BY W. W. STODDART, F.C.S., ETC.

At the present time, milk analysis is engaging the attention of many chemists, and eliciting the most discordant opinions. This may probably arise from local reasons, or difference in food or weather, or else what is more likely still, from the apparatus employed in the research. Many analysts have, and still do make use of the old-fashioned graduated lactometer, the indications of which are worthless and deceptive in most cases.

I am anxious now to bring before your notice a most ingenious piece of apparatus, invented by Mr. Horsley, of Cheltenham, and which, I think, will turn out extremely useful. It shows the fat or cream distinct and perfectly separated. By it you can calculate the weight per cent., and estimate the casein and the sugar and salts with great ease and rapidity. Indeed, the whole operation only takes ten minutes, or the quarter of an hour, and the results may be kept for observation for any length of time, an advantage of no mean importance when legal consequences are dependent on the analytical evidence.

The method of analysis is this. The milk to be tested is poured into the tube till the first mark is reached, measuring off 250 grains. Methylated ether is then added until the next mark, B, is reached, and the whole well shaken together for five minutes. Methylated spirit is next poured in to 10° of the graduations, C, and again shaken for five minutes. On placing the tube in the stand, the fat will rise to the top as a bright yellow oil, the measure of which will indicate the *weight*, because each graduation is equal to 4·15 grains of fat. The casein separates and falls to the bottom of the tube as a white mass, capable of being strained off, dried, and weighed. The remaining fluid, after evaporation to dryness, will give the amount of sugar and salts.

As an example, the milk in No. 1 tube is a rich sample from an Alderney cow, and it will be seen that the fat occupies four of the graduations on the tube from 250 grains of the milk.

Therefore—

$$\frac{4 \times 4 \times 4{\cdot}15}{10} = \ldots\ 6{\cdot}64 \text{ fat.}$$

Then the sediment = 10·8 grains, so that

$$\frac{10{\cdot}8 \times 4}{10} = \ldots\ 4{\cdot}32 \text{ casein.}$$

Residue after evaporation $= \frac{14{\cdot}2 \times 4}{10} = \ldots\ 5{\cdot}68$ salts and sugar.

Total solid contents = 16·64 per cent.

The other tubes would equally show the same thing, for instance—

No. 2 tube shows 3 graduations $\frac{3 \times 4 \times 4{\cdot}15}{10} = 4{\cdot}98$ p.c.

It has had 25 per cent. of water added.

No. 3 shows 1 graduation . . $\frac{1 \times 4 \times 4 \cdot 15}{10} = 1 \cdot 66$ p.c.

It has had 50 per cent. of water added, and had 25 per cent. of fat removed.

No. 4 shows 2 graduations = . $\frac{2 \times 4 \times 4 \cdot 15}{10} = 3 \cdot 32$ p.c.

This has had 50 per cent. of water added.

No. 5 contains milk made from the Aylesbury condensed milk by adding 4 pints of water.

The tube shows 1·5 graduations $= \frac{1 \cdot 5 \times 4 \times 4 \cdot 15}{10} = 2 \cdot 49$ p.c.

No. 6 contains milk made in the same way from the Anglo-Swiss Company.

The tube shows 1 graduation $= \frac{1 \times 4 \times 4 \cdot 15}{10} = 1 \cdot 66$ p.c.

The tube, if wished, can also be used as an ordinary lactometer, for every degree is $\frac{1}{100}$ of the whole. Another purpose for which I have used Mr. Horsley's tube, is for the analysis of butter, and to show whether or no it is adulterated or lowered with any other fat, etc. A weighed portion of butter is placed in the tube and dissolved in ether; when dissolved as much as possible, water is added to mark B, and well shaken. Methylated spirit is then poured in till mark C is reached, and then well shaken for a minute or two and laid aside to settle. The butter is then measured off and calculated as before. The following example will explain:—Fifty grains of pure fresh butter were placed in the tube, and ether poured in to A. By a little agitation, the butter soon dissolved, and water being added to B, the whole solution well shaken. Methylated spirit was poured in *to the top* of the graduation, and after shaking for one or two minutes, laid aside to settle. In this case, $11\frac{3}{4}$ degrees were obtained, therefore, the sample consisted of $97\frac{1}{2}$ per cent. of pure butter, for

$$11 \cdot 75 \times 2 \times 4 \cdot 15 = 97 \cdot 52.$$

Any adulterating fat will be seen on a layer at the bottom of the bright yellow butter oil. The curd, on the contrary, will fall slowly to the bottom of the tube.

A vote of thanks to Mr. Stoddart having been passed,

Professor REDWOOD said: I should like to ask Mr. Stoddart one question, a satisfactory answer to which would be very valuable to myself and others. I wish to know how he distinguishes between the fat which he says is an adulterant of butter, and the butter itself; what kind of chemical distinction does he draw between butter and ordinary animal fat which would have a similar melting-point? I confess I am not acquainted with any real distinction between the various fats consisting of stearin, palmatin, or olein. If this mode of proceeding does afford a reliable method of distinguishing between butter fat and such a substance as yellow beef fat, which I believe is often added to butter, it would be a most valuable process, for at the present time this is a great difficulty with all analysts.

Mr. STODDART: I would just say, in reply to Professor Redwood, that if he will get an ounce bottle, and put into it 50 grains of butter, half fill with ether, and give it a good shake, if it be good butter it will all dissolve, except the salts and the water. To get rid of that I usually mix the butter with boiling water, so as to free it from salts and soluble matter. If the butter be genuine, it will, when treated as I have stated, all dissolve; but if lard or meat fat be added it will not dissolve, on stirring for two or three minutes it will go to the bottom. Some people would say, without further consideration, that what sank to the bottom was fat, but it may be curd, for what country people call whey-butter has frequently 8 or 9 per cent. of curd in it. You have, therefore, to distinguish whether it is fat or curd. A very simple way of determining it is to put a small portion on a glass slip and heat it; if it is fat it will, of course, melt, and if it is curd it will dry and go to powder.

Mr. RIMMINGTON inquired where these tubes could be obtained?

Mr. STODDART: They may be had of Mr. Balcomb, chemist, Cheltenham.

The Conference now adjourned, it being past five o'clock

FRIDAY, *August 7th.*

The Conference re-assembled in the lecture hall of the Pharmaceutical Society at ten o'clock; Mr. Groves, the president, occupying the chair.

The proceedings commenced by Professor Attfield, the general Secretary, reading the list of names of gentlemen who had been proposed as members, and who were unanimously elected.

The following paper was read by Mr. H. C. Baildon on—

BRIEF NOTES ON THE BARK OF THE BLACK ALDER TREE (CORTEX RHAMNI FRANGULÆ.)

BY H. C. BAILDON.

I think I may assume that most of the members of the Conference that are present have read Mr. Ince's contribution regarding this bark, which appeared in the *Chemist and Druggist* of June last. This paper, and my remarks in the *Pharmaceutical Journal* of the 9th of May, have already brought it into considerable use, and I feel confident that it will be found to be a very valuable addition to the rather limited list which we possess of vegetable aperients. In making these brief remarks, I am more anxious to elicit the opinions of those members who have experimented upon it, than to add to what I have already communicated. To prevent disappointment, it is very desirable that the bark used corresponds to the description of it given in the German Pharmacopœia, viz., "the cortex of the younger trunks and the larger branches of the indigenous shrub gathered in the spring." The sample now shown is taken from a bale recently received from Antwerp, and corresponds with this description. The concentrated decoction prepared either *in vacuo* or by Mr. Giles' process of exhausting successive quantities of the bark, will, I think, be found the most eligible form for its administration, and this is now ordered in prescriptions by some of the leading practitioners in Edinburgh. In addition to the concentrated decoction, I have prepared a strong tincture by distilling off a great part of the rectified spirit, a drachm of which represents an equal quantity of the bark. From its small bulk, it may occasionally be found a convenient preparation. A sample of extract is also on the table, and it is probable that in the form of pills it may be advantageously used. I know Mr. Giles has experimented a good deal upon this bark, and I should be glad to hear the conclusions he has arrived at as to its value in pharmacy. Both Mr. Ince and Mr. Umney have also paid considerable attention to this drug. I am also glad to observe Dr. De Vrij present, as he will be able to state the estimation in which it is held in Holland and on the Continent.

A vote of thanks was passed to Mr. Baildon.

Mr. INCE: Mr. Baildon has made an allusion to a paper which he has kindly described as my own on the Cortex rhamni frangulæ. I was very happy to be able to take his facts and experiments, and arrange them into a connected and intelligible form, but I cannot claim the slightest originality for the remarks I then made. I am bound, however, to say that I approached the subject entirely from a personal motive, because the greater part of my occupation being sedentary, it has induced a constant constipation which is extremely hurtful in its effects. Now, though I am strongly opposed to anything in the shape of testimonials at meetings of this kind, I think we must distinguish between testimonials and testimony, and that I am entitled to bring forward the results of my own experience with regard to the use of this drug. I first became acquainted with it by reading an old paper by Mr. Baildon, read, I think, at Edinburgh, but which, being short, did not at the time receive much attention. He there described the manner in which this drug was used in Holland, where I found the people were in the habit of taking a small quantity of the bark, say half an ounce, putting it into a pint of water and evaporating down to one-half, which was then taken in the ordinary doses of a decoction, *i.e.*, about one ounce and a half at a time. I thought it would be well to try the effect of this very simple remedy, and the result was truly marvellous, though I am afraid of using exaggerated terms. It answered in every possible respect the purpose intended. Now, it is well known that it is of no use attempting to introduce a mere plain decoction into general medical practice, because it will never be faithfully executed; persons accustomed in ordinary domestic life to make preparations of this kind very successfully, seem to lose their presence of mind when the same thing comes under what may be called the scientific aspect, and, in practice, decoctions are very seldom well prepared. I was therefore rejoiced to find that a good preparation of the cortex was to be introduced, as it has now been, by Mr. Baildon. The method is simply to exhaust the bark by cold water, exactly in the way originally proposed by Mr. Giles, and then concentrate into a liquor, not into an essence, which I consider very objectionable, as being much too concentrated. This method seems to me to leave nothing to be desired; the whole of the active principle of the bark seems to be got out, and it is then evaporated to a proper consistency *in vacuo.* This makes a very attractive-looking liquor, and I can answer personally for its efficacy. It is very difficult to get an aperient which is not accompanied by distressing effects; senna, for instance, is often followed by very bad results, and it is also uncertain and distasteful. Now, the cortex rhamni has certainly the advantage of an agreeable taste, it produces no bad after-effects, and, as far as my experience goes, is an exceedingly satisfactory and efficient preparation. I think, therefore, it is quite deserving of a more definite notice than has yet been accorded to it, and might well be added to any future Pharmacopœia.

Mr. GILES: I am quite prepared to fully endorse everything which has been said in praise of this article by Mr. Baildon and Mr. Ince. Mr. Baildon has, I think, re-introduced a most valuable agent into our materia medica, and I am disposed to say not only a better aperient than any other, but the only aperient that we have. We have many cathartics, but not aperients. Perhaps this may seem an artificial distinction, but the especial character of the *Rhamnus* is that it appears to be an invigorating stimulus to the bowels, and not an irritant. Irritants are followed by a sort of collapse, the over-stimulation is followed by a reaction, and very often, as we know, by greater constipation than preceded their use. Now, the *Rhamnus* has the exactly opposite character; it appears to regulate the conditions of the functions of the body, and I do not think this is limited to the action of the bowels. People may take it, and after it has produced its effect, instead of requiring to take more, they become more and more independent of it. It is a remarkable fact, as has been pointed out by Mr. Baruchson of Liverpool, that the same doses, or rather less doses than the original one, continue to be operative. I have met with cases where it has been said to fail, but I believe that is because people do not distinguish between this regulative aperient action and a cathartic action. They want some *ad captandum* explosive purgative, and are disappointed if they do not meet with it in *Rhamnus frangula* bark. But I think they are looking for that which is just undesirable, and to what we have been driven to use for want of something better, but which I think will be superseded by a larger experience of the *Rhamnus frangula.* One does not go far into therapeutics at a meeting of this kind, especially if they touch on delicate functions; but I must say I have reason to believe that the action of this article in restoring the regularity of the alvine action in females, also leads to greater regularity in other constitutional functions, and that of course is a matter of very high importance. I cannot say that I have yet sufficient general experience in that direction, but I am strongly induced to believe that it is so, and I propose to carefully watch its action in this respect. So far as to its general therapeutical effects. As to its preparation, obviously, as Mr. Ince says, we require something which shall be more permanent than a decoction, although it is a remarkable fact that the decoction, in virtue apparently of some prussic acid constituent, is very permanent, and my opinion is it would keep, even in the summer, for a month. Still we want something perpetually permanent, and that is easily obtained in the form of a liquor, such as Mr. Baildon and myself agree in approving. The reduction of things *in vacuo* is unquestionably the best form of reduction, but there is no necessity for any reduction at all in this case, because it is perfectly easy to prepare the liquor in its due strength by the first process, and that is the course I adopt, not by a cold-water infusion, but by simply stewing for a quarter of an hour consecutive portions, by which means I easily get a result three times as strong as the decoction which Mr. Baildon introduced, and it has simply to be preserved by the addition of a sufficient quantity of spirit. You then have a liquor which has been subject to no process of evaporation, or any further action of heat than in the ordinary decoction, which is quite permanent. I have watched the action of the two, and there is no appreciable difference in their value. I think Mr. Baildon has been the means of introducing to medical practice in this country a most valuable remedy, and I have not the smallest doubt the more it is investigated the more it will be approved, and that it must ultimately find a place in our official materia medica.

Dr. DE VRIJ: I can only confirm what has been said by all three gentlemen who have spoken about this medicine, which is very much used in Holland. A brother of mine, who was a physician, used it for many years without any bad effect whatever, and, contrary to the majority of other purgatives, he did not become accustomed to it; in fact, the same dose always had the same effect. He used the decoction, but I quite agree that this preparation is much better, because you can keep it longer, and always have it at hand.

Mr. SIEBOLD: It has long been a matter of surprise to me that this article has not found its way into the British Pharmacopœia, because for the last twenty-one years I have known it to be used uninterruptedly in Germany, where it has been universally liked as a very pleasant purgative—pleasant not only in taste, but also with reference to its effects. Considering the intimate intercourse which now exists between the different European countries, it seems astonishing that a medicine can be very much appreciated for many years in one country, and yet hardly be noticed in another so close to it. I think that meetings such as the present will tend to rectify this evil, and that, in course of time, those medicines which are proved to be of great value, will not simply be the property of one country, but of all the world.

Professor BENTLEY: I have been very glad to hear the repeated observations to-day as to the merits of a substance which has been certainly known in this country for more than twenty-five years. As long as I can recollect anything connected with scientific subjects, I remember Dr. Pereira mentioned to me, when I was a colleague of his at the London Hospital, this very bark, of which he gave me a specimen, not knowing exactly what it was. I had then an opportunity of examining the plant from whence it was derived, and determining its botanical source. I know that at that time it was in use in Germany, as Mr. Siebold has said, and from that period to this it has always been esteemed as a medicine of considerable value. It is certainly a remarkable fact that such a substance should not have received more attention in this country, and I am very glad to hear the testimony now given as to its efficacy. I should like, however, to have heard whether, as Mr. Baildon has brought it before the notice of the profession for some time, and as Mr. Giles has investigated its properties very carefully, it has been tried at the Bristol Infirmary, or if any results have been obtained by physicians; because it is very important not only to have the testimony of pharmaceutists to its value, but, if it is to be strongly recommended, that this should be supplemented by the acknowledged experience of those whose special duty it is to take notice of these remedies. This subject raises a question which I have more than once alluded to in this room, as to the desirability or necessity of having some list of medicines which are of considerable reputation, or which are known to have some repute on the Continent, or in America, or elsewhere, added to our Pharmacopœia as a secondary list.

The President: I quite agree with what has been said as to the desirability of introducing an aperient of the character ascribed to the Cortex rhamni frangulæ, and I think we are greatly indebted to Mr. Baildon for bringing it forward. When he first introduced it at Edinburgh I obtained a few samples from him, made a decoction, which I preserved with glycerine, and tried it on myself. But I must say that I cannot endorse all that has fallen from Mr. Ince and Mr. Giles with respect to it, for I did not find any definite action beyond that of other purgatives, still, I shall be inclined, after what has been said, to try it again.

Presence of Lead in Liquor Ammoniæ Acetatis.

BY LOUIS SIEBOLD.

Some time ago, I was asked to certify the total absence of lead in a sample of water used for the manufacture of soda water. 500 c. c. of this water, acidulated with pure HCl and treated with H_2S, remained clear and colourless.

In order to detect the smallest trace of lead, if present, a somewhat larger quantity of the water was slightly acidified with acetic acid, mixed with two fluid drachms of strong solution of ammonium acetate (to prevent any precipitation of sulphate of lead), evaporated to the bulk of two fluid drachms, filtered and treated with H_2S. A very distinct black precipitate was obtained, which, upon examination, proved to be sulphide of lead. The striking reaction obtained contrasted so strangely with the entirely negative result of the first experiment that I felt convinced the quantity of lead found did not emanate from the water, and upon now testing two fluid drachms of the same solution of ammonium acetate with H_2S, I obtained as distinct a precipitate of PbS as in the previous experiment. I then prepared some fresh solution of ammonium acetate from pure acetic acid and pure solution of ammonia, and using two drachms of this in precisely the same way as before, the water under examination was found to be absolutely free from lead. I preserved the remainder of the solution of pure acetate of ammonium in a white glass stoppered bottle, and marked the date when it was made and tested on the label. About a month afterwards, I used some of this solution for the same purpose as before, and was much surprised to find it contaminated with lead, which it had evidently dissolved from the glass bottle in which it had been kept. This circumstance induced me to procure, from different retail establishments, samples of Liquor ammoniæ acetatis concentratus (as generally sold by wholesale houses), which is eight times as strong as the B. P. article. Out of ten samples examined only two were free from lead. My own stock was found to be thus contaminated, though it was certainly free from that metal when it was made. I have also examined four samples of Liquor ammoniæ acetatis of the B. P. strength, but could only find very small traces of lead in one of them.

The solvent action of ammonium acetate upon sulphate of lead and other insoluble lead compounds is well known, but its power of dissolving lead from glass has, I believe, not been previously observed. Fresenius, in describing the extraction of lead from substances insoluble in water and acids by means of ammonium acetate, states in a foot-note, that this method is not applicable for the detection of lead in silicates. Yet the above experiments show that by the long-continued action of Liquor ammoniæ acetatis upon glass containing lead, an appreciable quantity of the latter is dissolved, and as this is undoubtedly a most objectionable impurity, I would suggest that this liquor, and especially the concentrated preparation, be kept in bottles free from that metal.

The President: Mr. Siebold's investigations show a very possible source of error in the analysis of potable water. The action of acetate of ammonium as a solvent of some of the soluble lead salts was pointed out some twelve months ago in the case of iodide of lead. An instance of that occurred to me the other day. I expected to get a precipitation of iodide of lead, but found that I got none until I added some nitric acid. I could not make out the reason of that for some time, but at last I found that I had acetate of ammonium in the liquid, so that the iodide of lead was kept in solution. I beg to propose a vote of thanks to Mr. Siebold for his paper.

The vote of thanks passed unanimously.

The Adulteration of Scammony.

Mr. Benger then read a paper by Mr. Greenish on "The Adulteration of Scammony." We have been requested by the author to defer the publication of this paper for a short time.

A vote of thanks was passed to Mr. Greenish for the paper.

Mr. Hanbury: One point in the paper interests me much, and that is Mr. Greenish's observations about the powder which is found on the outside of the pieces of scammony. I was lately much surprised to hear the presence of starch in scammony accounted for by the notion that it was used to prevent adhesion of the lumps. Mr. Greenish says that he does not find any starch on the exterior of the pieces nor any calcareous matter. I cannot speak as to starch, but I long ago noticed that the powder that occurs on the outside of a piece of scammony does not effervesce, and therefore is not identical in nature with the calcareous matter used to adulterate the drug. There appears, in fact, no ground for supposing that the pieces are rolled in any powder in order to prevent adhesion. I regret that Mr. Greenish has not sent the specimens he alludes to, because I should like to know what are the drugs he terms Angora and Syrian scammony. I am not aware of any such distinctions existing in the London trade.

Mr. Giles: I should just like to refer to the introduction in our Pharmacopœia of the resin of scammony, and the retention of the virgin scammony, one being used for some preparations and the other for others. I believe this has been discussed before, but it appears to me there ought to be some conclusion arrived at as to which is the best, and that that should be adopted. I do not see the advantage of using virgin scammony for the pill, and resin of scammony for the extract.

The President: Have you not the option?

Mr. Giles: No.

Professor Redwood: I do not know whether Mr. Giles has sufficiently taken account of one circumstance, which certainly did come under the notice of the Pharmacopœia Committee, and that was that it has not been quite clearly decided which is the best of the two, or whether there is any difference between them. Some advocate the use of resin of scammony, and others consider the virgin scammony more active and reliable, and it was thought, as there were two preparations similar in their effect, that at least we might give an option to medical men to select which preparation they would prescribe. I think that was the motive which led to the introduction of the new form of resin of scammony in the one case, and its not being adopted in the other.

The following papers on hydrocyanic acid were then read:—

Note on the Diluted Hydrocyanic Acid of Pharmacy.

BY MR. BARNARD S. PROCTOR.

The variability of pharmaceutical hydrocyanic acid has long been felt to be of serious moment, and has recently become a matter of great notoriety, attention having been called to the extent of the variations by analysts in sundry neighbourhoods. In June, 1873, Mr. Abraham, of Liverpool, gave the results of four examinations as 2·11 per cent., 2·02 per cent., 1·64 per cent., and 1·30 per cent.

At the Pharmaceutical Conference at Bradford, Mr. Siebold stated that he found it vary from about 2·00 per cent. to 0·25, or even less, and he attributed the variation to evaporation from imperfect stoppering of the bottles.

Dec. 27, 1873.—Mr. Towerzey having titrated nine samples, gave his results as 1·93, 1·52, 1·36, 1·32, 1·26, 1·22, 1·16, and 0·26 per cent. Other analysts, at different dates and places, gave similar testimony.

That such a condition should continue to exist is highly unsatisfactory—we may even say a disgrace to pharmaceutical chemistry. Many remedies have been proposed, and I now purpose to bring before pharmacists the unripe fruit of my small labour in this field.

Two objects seem desirable of attainment—first, the discovery of some simple, cheap, rapid, and accurate process for preparing small quantities of hydrocyanic acid of the official strength, by which every pharmacist could prepare his week's or month's supply, and throw away his old stock without any unreasonable sacrifice of time and money; the second object being the production of an acid of official strength which, by some simple addition or alteration, would be less liable to variation in strength by keeping.

It is unnecessary for me to recount in detail what has been done in these respects, but I may just mention that two processes for extemporizing the solution, one from the decomposition of cyanide of silver with dilute hydrochloric acid, leaves nothing to be desired but economy; and the other, in which cyanide of potassium is decomposed by solution of tartaric acid, depends upon a salt liable to deliquescence and decomposition, and the product is contaminated with a trace of organic acid, which, it has been said, though I do not know upon what evidence, has the reverse of a conservative action.

The official acid is liable to loss of strength from at least two causes—evaporation, and the formation of paracyanogen, probably also some other decomposition not indicated by a visible change in appearance. The customary precautions against these sources of loss are, careful stoppering and inversion of the bottles to retard evaporation; the exclusion of light, and the addition of sulphuric or hydrochloric acids to protect it from decomposition.

My first experiments were with the view of finding some solvent which, from a greater affinity for the acid, or from a volatility more equal to that of the acid, would diminish the variation dependent upon evaporation.

Alcohol and ether naturally suggested themselves, and in November last I made three specimens of the acid to test the relative merits of these solvents.* The first solution, prepared with water for comparison, and marked A; the second being rectified spirit, and marked B; the third, C, being ether. These acids, when prepared, were decanted into three well-stoppered bottles of the same size, and having necks of precisely the same width (the stopper of any one fitting the other two).

The acids were decanted from the precipitates on the 12th of November, and at once tested volumetrically with nitrate of silver.

A	contained	1·86	per cent.	of HCy.
B	"	1·86	"	
C	"	1·92	"	

In these, and the subsequent determinations, I place little reliance on the second decimal figure. My object is to ascertain what can be conveniently done as an ordinary pharmaceutical process. I therefore operated with ordinary pharmaceutical weights and measures. The error in measuring thus may readily amount to two or three units in the decimals, but this is of little moment, as the variations in actual practice are so large as not only to affect the fractions, but the integers. But to return to the experiment.

The phials containing these specimens were placed in my office, stoppers uppermost, not exposed to a strong light, and the stoppers were removed, half a minute to two or three minutes at a time, several times a day for a week; this being supposed to represent, in a rather exaggerated form, the kind of exposure which it is desirable a pharmaceutical acid should stand in actual practice. To ensure that the specimens were equally treated, the stoppers were always taken out and replaced in rotation, the stopper being taken out of A and laid beside the bottle, while the same was done for B and C, and then, after a short interval, replaced again in the same order.

On the 19th of November (*i.e.*, at the interval of a week), they were again subjected to analysis, with the following results:—

A = 1·76 per cent.
B = 1·80 "
C = 1·84 "

The loss in all cases was very much smaller than I anticipated, though the comparative losses were in the order which theory had suggested.

The specimens were then exposed to a more severe test, by the stoppers being removed from the bottles for periods varying from half an hour to three hours daily for eighteen days; at that date (Dec. 6, 1873,) they were again analysed, with the following results:—

A = 0·84 per cent.
B = 1·16 "
C = 1·84 " *

These results very much astonished me.

Bearing in mind the numerous statements of rapid loss by evaporation, it seemed scarcely credible that the aqueous solution should retain nearly half its original strength after such exposure. Take for comparison the statement of Mr. L. Siebold, whose accuracy I cannot question. In illustration of the rapid loss by evaporation he says:—"I purchased a two-ounce bottle of the Pharmacopœia acid, freshly made, from a very respectable wholesale house, and at once estimated its strength by volumetric analysis. It contained 1·6 instead of 2 per cent. It was kept in the same bottle without being tied over, and the escape between stopper and neck was noticeable at some distance. After twenty-four hours it contained 1·2, after two days hardly 1 per cent., and after a month it contained only traces of HCy."

The strength of the ethereal solution was also unexpected; for, though the ether had evaporated much, we

* The general formula being—Cyanide of silver 40 grains diffused through 7 fluid drachms of the solvent, and 36 minims of hydrochloric acid added, the mixture well shaken and allowed to subside. The solution decanted after a week (though probably an hour might have sufficed).

* These having been kept till Jan. 31, 1874, without any special precautions, but occasional opening, yielded:—

A . . . . . 0·48
B . . . . . 0·76
C . . . . . 1·80

could not have predicted that it would have passed off in as great a proportion as the HCy, since, of the two liquids in their anhydrous state, HCy is the more volatile; but, on the other hand, it is quite supposable that a compound of the two may be formed, less volatile than either separately.

With the view of estimating the comparative affinity of water and ether for the acid, I took equal volumes of ether, and a specimen of commercial hydrocyanic acid which contained 1·90 per cent. of HCy; after agitation and subsidence, the ethereal solution contained 1·48 per cent. of HCy, and the aqueous only 0·5 per cent. This total is apparently more than the aqueous acid contained, but the discrepancy is accounted for by the ethereal solution being smaller in bulk—a portion of the ether having been dissolved by the water.

From this result it would appear that the ether has about three times the affinity for the acid which is possessed by water.

I have made no attempt to estimate the affinity of alcohol for the acid, and a considerable time must elapse before we can determine the relative keeping qualities of acids in which the menstrua are mixtures of alcohol and ether.

For the present I have left this part of the subject to try a few experiments upon processes for the extempore preparation of the acid in combination with any of the solvents.

The problem is to find a base which forms a definite cyanide not liable to spontaneous change under ordinary keeping, but readily and completely yielding its acid, the base being completely precipitated by one of the common acids, from a solution in one of the three solvents already spoken of.

Cyanide of potassium, as met with in commerce, is very impure, and liable to decomposition, but that which has been crystallized from spirit is probably sufficiently uniform and stable to be used with satisfaction if a better salt be not found. A specimen which I have had for eight years, *not* very carefully corked up, contains 80 per cent. of its theoretical cyanogen, 7 per cent. of water, part of which was probably present when new, and so much carbonic acid as to effervesce on the addition of tartaric acid to a strong solution, though not to do so visibly, when the strength of the solution is calculated to yield hydrocyanic acid of 2 per cent.*

Fifty grains of this salt, with 980 grain measures of rectified spirit, and decomposed with a little more than an equivalent of sulphuric acid, gave a bulky precipitate of potassium sulphate, which, after a few days, contracted, and became contaminated with a brown matter, perhaps paracyanogen. These proportions were calculated to give an acid of 2 per cent., had the cyanide been perfect, or an acid of 1·6 per cent. with the sample of salt used: it was found, however, to contain only 0·68 per cent., and a similar specimen prepared in the same way, except that the spirit was mixed with $\frac{1}{8}$ of ether, presented similar appearances, and gave 0·74 per cent. of HCy. Fifty grains of the same cyanide dissolved in 980 grain-measures of water, and decomposed with an excess of tartaric acid, speedily deposited its cream of tartar, and yielded a solution containing 1·56 per cent. of HCy—1·60 per cent. being the strength it was calculated to be.

A similar mixture made with rectified spirit in which neither the salt nor the tartaric acid is so freely soluble, was titrated after standing an hour, and only indicated 0·28 per cent. of HCy. After a lapse of three hours the titration was repeated with the same results. After two days a pale brown granular deposit had taken the place of the lower part of the precipitate, and the per centage of HCy had increased to 0·36.

A third modification of this formula was made by dissolving the acid and cyanide in separate portions of water, mixing the solutions, and after the lapse of an hour adding an equal bulk of rectified spirit, the general proportion between solvent and solids being maintained. This solution contained 1·64 per cent. HCy.

A fourth modification consists of cyanide of zinc and potassium precipitated by tartaric acid; this has an advantage over the other in the greater stability of the salt, which does not absorb water or carbonic acid, nor part with cyanogen by ordinary keeping. It has the disadvantage of yielding a more bulky precipitate.

The details of the experiment were as follows: —

Two grams of cyanide of zinc and potassium dissolved in 42·8 grams of water (Towerzey's form as a substitute for B.P. acid) when titrated gave results equal to 1·92 per cent. HCy. Four grams of tartaric acid being added to the solution yielded a bulky precipitate which, after standing three hours, occupied one-third the bulk of the liquid. The clear liquid again examined was found equal to 1·88 per cent. HCy. The phial being set aside from the time it was made, about the middle of February, till the middle of July, the sediment had diminished to about $\frac{1}{5}$ the bulk of the liquid, and though only stopped with a common cork, the strength of the acid was still 1·86 per cent. The apparent loss of strength consequent upon the addition of the tartaric acid is no doubt due to the increase in bulk due to this addition.

The solution of course contained a little acid tartrate of potassium and only a trace of zinc.

It has been suggested to introduce this double cyanide of zinc and potassium as a substitute for hydrocyanic acid for medicinal purposes, it being supposed, on theoretical grounds, that it would have similar therapeutic value, together with constancy and permanence; but, however much may be expected from it in these respects, it cannot, for a considerable period at least, displace the acid which, with all its faults, has had a good reputation for several generations.

A fifth modification consists of cyanide of potassium and tartaric acid, dissolved in small portions of water, mixed, and, after a few minutes, adding spirit and ether, the proportion of solvents to solids being still the same, but the solvent consisting ultimately of equal parts of water, spirit, and ether.

This being made with the new sample of cyanide, should have yielded an acid of 1·88 per cent., but it was found to be 1·78.

The cyanides of lead, calcium, and barium to be decomposed by sulphuric acid appeared next in order of prospective merit, but cyanide of lead is said to be an uncertain compound, containing variable proportions of oxide.

I am also informed by Messrs. Hopkin & Williams, that "the cyanides of calcium and barium, prepared from the ferrocyanides, are worthless, and when prepared in solution by neutralizing baryta or lime water with hydrocyanic acid, decomposition sets in at once, and in the course of an hour or so black solutions result quite free from cyanogen in any shape."

I have consequently limited my experiments to the materials already mentioned.

Of fifteen specimens made by different formulæ and kept for five months, one only has turned brown; it contains cyanide of potassium, water, sulphuric acid, and spirit, and gives an alkaline reaction with red litmus, though it has a strong odour of HCy, and contains 1·58 per cent. now, against 1·64 while new. Two other specimens turned slightly yellow; they were prepared from cyanide of potassium, with sulphuric acid and spirit, and, as before mentioned, had deposited a brown sediment along with the potassium sulphate.

Comparing the different specimens containing water only with those containing water and spirit, I do not note any very clear advantage in the keeping quality of the alcoholic, except in the first series, previously named A, B, C. The following table gives the dates at which

* A new sample of crystallized cyanide of potassium I find contains 94 per cent. of the theoretical cyanogen—a little carbonic acid and moisture.

these samples were examined, and their value in percentages of the B.P. standard :—

	A.	B.	C.
November 12, 1873. . .	93	93	96
„ 19, „ . . .	88	90	92
December 6, „ . . .	42	58	92
January 31, 1874 . . .	24	38	90
July 17, 1874	6	32	—

In drawing any conclusions from this table, it is, of course, necessary to take into account the exposure to which they were subjected, which has already been described, except as regards the last date. Between January and July they had been occasionally, but not very frequently, opened, and not much exposed to light. What little remained of C, after the January examination, had entirely evaporated before July. I have, therefore, not any evidence of the stability of the ethereal solution under long keeping.

Eight specimens, made by various formulæ in February, and examined again in July, had lost on an average 0·085 per cent. of HCy, or about 5 per cent. of their original strength, two of the bottles having glass stoppers of ordinary quality, the others having common corks.

I do not observe any difference in the keeping quality of the samples prepared respectively with tartaric and with sulphuric acid; the latter, however, necessitates the use of spirit to precipitate the sulphate formed.

Looking over these experiments, the conclusions which they point to are, that the aqueous hydrocyanic acid does not lose by evaporation so rapidly as some recent essayists would have us believe; that the alcoholic acid loses strength less by evaporation than the aqueous; and that the ethereal acid suffers comparatively little from this cause. We also find that as extempore processes the decomposition of cyanide of silver by aqueous hydrochloric acid leaves nothing to be desired but economy; that crystallized cyanide of potassium may be obtained commercially pure enough for extemporizing hydrocyanic acid; and that it is permanent enough for practical use; that in the decomposition of cyanide of potassium by sulphuric or tartaric acid in the presence of alcohol only part of the cyanogen is liberated as hydrocyanic acid, but that after the precipitation of the potassium as an acid tartrate in the presence of a small quantity of water, the subsequent addition of alcohol or alcohol and ether yields an acid not deficient in strength; that crystallized cyanide of zinc and potassium may be substituted for the simple cyanide of potassium with advantage, being free from deliquescence and tendency to decomposition on exposure to the air.

I may add that a common cork appears to be all that is necessary to prevent loss of acid by evaporation, and is probably better than a common glass stopper.

The following may be regarded as a cheap and easy method of extemporising hydrocyanic acid of B.P. strength :—

Water	1 ounce.
Cyanide of Zinc and Potassium .	22 grains.
Tartaric Acid	40 „

Dissolve the cyanide in the water, add the acid, and allow the precipitate to subside; decant the clear liquor, and preserve it in a corked phial; renew the stock at intervals not exceeding three months.

My observations have only thrown a negative light upon the causes of the great variation found in the hydrocyanic acid of the shops, and leave us with the impression that something more to the point, both as regards causes and remedies, remains to be done.

Some Recently Proposed Substitutes for B.P. Hydrocyanic Acid.

BY W. A. SHENSTONE.

At a meeting of the Bristol Pharmaceutical Association, in December, 1873, a paper was read by Mr. Towerzey on hydrocyanic acid. The author gave, in his paper, the results of some experiments which showed that the strength of the hydrocyanic acid used in pharmacy has not by any means improved since attention was first called to the subject by Dr. Tilden, in 1871, and he proposed as a substitute the double cyanide of zinc and potassium, adducing the result of an experiment to show that this compound has not the disadvantage of volatility. In the course of the discussion which followed the reading of this paper, Dr. Tilden suggested that experiments should be tried with an acid one-tenth the strength of that at present in use, as it seemed probable that the loss of strength through volatilization would be much decreased by the use of so weak a solution, and because there would be no necessity to obtain the prescriber's sanction to the use of such a preparation in the place of that ordered in the Pharmacopœia. I am aware that at the last meeting of the Conference, the use of a more dilute acid and also of some of the metallic cyanides was proposed, and that averments of their greater stability were made in support of the several propositions; but as I have no knowledge of any experiments having been brought before English pharmacists, either on very dilute hydrocyanic acid or on solutions of metallic cyanides of a convenient strength, I have, during the past few months, endeavoured to carry out Dr. Tilden's suggestion, and have also given some attention to the zinc and potassium cyanide. It is the results of my experiments that I have to place before the members of the Conference.

Hydrocyanic Acid.—Some Scheele's acid, containing some free hydrochloric acid, was diluted, and the amount of HCN determined in two portions by the volumetric method with silver nitrate, the percentage found was ·186, ·185 respectively. Two other portions were placed in white glass bottles, one of them was closed with a stopper, the other merely covered over with unsized paper; each of them was about one-third full, and they were kept in the dark. At the end of a month the bottle covered with paper was perfectly free from hydrocyanic acid; this may have been the case earlier, but I was unable to examine it during the interval. The stoppered bottle was kept from March 28th to June 16th (two and a half months) during which period it was opened twelve times, the bottle being carefully inclined as it would be in pouring out a portion of the contents each time; there then remained ·183 per cent. of HCN; an acid containing 2·28 per cent., under similar conditions, was reduced to 2·18 per cent., about three times as great a loss in proportion to the original strength of the solutions.

In my next experiments I kept the acid a much shorter time, but opened the bottles more frequently, that I might ascertain what depreciation of strength would occur when a bottle of the acid was frequently opened for removing part of its contents.

In each of six white glass-stoppered bottles was put some previously diluted acid, and the HCN determined in the first and last bottles filled; they contained ·206, ·204 per cent.

The four intermediate bottles, labelled A, B, C, D, were kept in the dark for one month, and opened A once, B twice, C three times, and D four times daily; on examining the contents, the following results were obtained:—

A	opened	28	times, contained	·202
B	„	56	„ „	·192
C	„	84	„ „	·194
D	„	112	„ „	·195

From these numbers it would appear that when the percentage of hydrocyanic acid has been reduced to ·195 or thereabouts, no further decrease in strength takes place from volatilization, unless the exposure to which it is subjected is very considerably in excess of what occurs in removing portions of the contents of the bottle holding it.

The second of my experiments indicates that when an acid of about ·2 per cent. is kept in a well-stoppered bottle, in the dark, and only occasionally opened, a very trifling loss occurs, and therefore it is evident that under these conditions the loss of strength by *decomposition* is unimportant. To decide whether this is also the case when the acid is exposed to light, two stoppered bottles, about one-third full of a solution containing ·206 per cent. of HCN were taken; one of them was placed in diffuse daylight; the other in a window (on which the sun shone some hours almost daily) for a month: the strength of the first was then found to be ·195 per cent., of the second ·199.

These experimental results seem to me to prove that a solution of hydrocyanic acid thus diluted, has the advantage of being considerably less instable than it is before dilution, and an additional point in its favour is, that it may be sucked up into a pipette with very little inconvenience and (taking ordinary care) without danger, which enables one to dispense with a balance in estimating its strength. Mr. Siebold has pointed out, and I suppose all agree with him, that the strength of such a variable medicine should be frequently determined, but, unfortunately, though many are able to do this, only a few have the necessary appliances. In estimating the strength of this weak acid, the only absolute necessities are a pipette of 20 c.c. capacity, graduated in cubic centimetres (costing 1*s.* 6*d.*), and a standard solution of silver nitrate, containing 6·296 grammes of the nitrate in a litre, 20 c.c. of which will produce turbidity when added to 20 c.c. of a solution of hydrocyanic acid, containing ·2 per cent. The necessary operations consist in measuring with the pipette 20 c.c. of the acid to be examined into a stoppered bottle containing a little solution of caustic soda, then rinsing the pipette, filling it to 0 with the silver solution, and dropping this into the bottle containing the hydrocyanic acid with constant agitation until the contents become turbid, the number of c.c. required to effect this, indicate the percentage. Thus, if 9 c.c. are required ·09 per cent. of HCN is present; if 19 c.c., then the solution contains ·19 per cent. of real acid. The whole process only occupies four or five minutes, and the results are sufficiently close for practical purposes, as with care differences of ·005 may be observed. In more accurate work, I measure the hydrocyanic acid in an ordinary pipette and drop in the silver solution from a burette; there is a considerable saving of time even here, but more apparatus is required.

Zinc and Potassium Cyanide.—That a solution of this salt does not lose strength from volatilization is, I think, sufficiently proved. I have, therefore, only endeavoured to ascertain whether it is stable or not when in dilute solution. Three white glass bottles one-third full of a solution of the salt in water, containing an amount equivalent to 2·00 per cent. of hydrocyanic acid, were labelled A, B, C. A was placed in the dark, B in diffuse daylight, C in a window through which it was exposed to sunlight for several hours every day. Each of them was opened from time to time, perhaps twenty times in all, and they were kept for one month. At the end of that time the contents of A contained the equivalent of 2·00, B 2·00, C 2·01 per cent. of HCN; in short, no change had occurred.

Three similar bottles, containing a solution of the salt just one-tenth as strong as the above, were treated in exactly the same manner for the same length of time. On examination it was found that the contents of A contained the equivalent of ·198, B ·199, C ·199 per cent. of HCN. The experiments were made during the hot weather of the present summer, and bottles C were at times quite hot to the touch. This, I think, shows pretty conclusively that zinc and potassium cyanide is an exceedingly stable compound, and would be much more reliable for medicinal use than the B. P. hydrocyanic acid, or, indeed, than the more dilute acid treated of in the first part of this paper. I doubt, however, if it would be legitimate to substitute it for the B. P. preparation without the consent of the prescriber, whereas in the vast majority of cases where water is an ingredient in medicines containing hydrocyanic acid, the use of this diluted acid would be both legitimate and beneficial.

On Hydrocyanic Acid.

BY LOUIS SIEBOLD.

The variable nature of the diluted hydrocyanic acid of the B.P. has been so fully discussed that not another word is needed in proof of the very unsatisfactory condition of this powerful medicinal agent. But though the evil has been fully recognized, no sound remedy for it has as yet been suggested. The improved methods of storing and dispensing the acid which have been proposed do not sufficiently prevent its volatilization, and do not even pretend to check its spontaneous decomposition. Several metallic cyanides have been proposed as substitutes for hydrocyanic acid on account of their greater stability; but unless we can induce the medical profession to forego the use of the acid in favour of such cyanides, we as chemists have no right to dispense them in its place, however fairly we may assume that their medicinal effect would be the same as that of the acid. Perhaps the best substitute of this kind would be the Aqua laurocerasi or the Aqua amygdalarum amararum of the *Pharmacopœa Germanica*, two preparations of equal strength, which, in Germany, are now exclusively prescribed instead of hydrocyanic acid, so that the latter is not even mentioned in that pharmacopœia. I alluded to the stability of Aqua laurocerasi in the discussion which followed the reading of my paper on the officinal acids at the last meeting of the Conference, but I was not then in a position to state whether the greater stability of this preparation is due chiefly to the very diluted state of its hydrocyanic acid, or to the fact of the latter being present in it in organic combination. The solution of this question appears to me of importance, for though we have no right to substitute Aqua laurocerasi for hydrocyanic acid, we are certainly entitled to dispense corresponding quantities of a pure but largely diluted hydrocyanic acid of known strength in place of the acid of the B.P., and it need only be proved that such a preparation is as stable or nearly as stable as Aqua laurocerasi, to put an end to all our difficulties in reference to hydrocyanic acid, without any appeal to the medical profession.

With this view, I have undertaken a number of experiments, the results of which I have now the pleasure of communicating to the Conference.

A quantity of pure dilute hydrocyanic acid, B.P., was procured from a very respectable wholesale firm, and at once mixed with nineteen times its weight of distilled water. A careful gravimetric examination of this mixture proved it to contain 0·0957 per cent. of HCy (the mean result of three determinations). A number of sixteen ounce bottles were filled with this weak acid, and two of these bottles, marked 1 and 2, with the stoppers securely tied over with bladder, were put into a cool place, laid on their sides, and protected from the light. The other bottles were also kept in a dark cool place, but in an upright position, and these were opened three times every day, each time for about a quarter of a minute, and their contents examined, at first once every day and afterwards once every week. These bottles were marked A, B, C, and D, and the samples of acid required for examination taken from each in its turn, so that a sample of A was examined on the second, a sample of B on the third, one of C on the fourth day, and finding no change a sample of D was tested at the end of a week, one of A after another week, and so on. 100 c.c. of the diluted acid were used for each determination, and were always measured in the same pipette. 5 c.c. of the normal solution of KHO were used in each experiment, and the standard solution of nitrate of silver containing one-tenth of a molecular weight of $AgNO_3$ in one litre was added each time, not only from the same burette, but from the same part of the burette, the instrument being refilled for every experiment. These precautions enabled me to obtain the most accurate results.

During the first three days, the acid was tested every day, but no change was observed in its strength. In each case 17·8 c.c. of the silver solution were required, indicating 0·0961 per cent. of HCN.

The acid was then examined from week to week, and the following results were obtained:—

	Used of solution of $AgNO_3$.	Per-centage of HCN.
During the first three days .	17·8 c.c.	0·0961
At the end of the 1st week.	17·7 c.c.	0·0955
" " 2nd " .	17·6 c.c.	0·0950
" " 3rd " .	17·5 c.c.	0·0945
" " 4th " .	17·3 c.c.	0·0934
" " 5th " .	17·0 c.c.	0·0918
" " 6th " .	16·8 c.c.	0·0907

showing that the acid kept exceedingly well for a month though the bottles were opened three times every day.

The bottle marked No. 1 was opened a month after it was filled, and its contents examined, 100 c.c. required 17·8 c.c. of the silver solution. The bottle marked 2 was not opened until two months after being filled, when 17·6 c.c. of the $AgNO_3$ solution were required for 100 c.c. of its contents. The acid in these two bottles, which had been kept carefully closed, had undergone no appreciable change within two months.

On the strength of these experiments I venture to recommend wholesale houses to supply, and retail chemists to keep, a dilute hydrocyanic acid containing $\frac{1}{10}$ of a per cent. of HCN., of which 20 minims are equivalent to 1 minim of the B. P. acid. This preparation might be conveniently purchased and kept in 8 oz. bottles, of which one should be in use at a time, and replaced by a fresh one a month after it has been opened, provided it lasts so long. The whole stock should be renewed as soon as the percentage of the acid becomes reduced to 0·095, which I feel sure would not be the case in less than three months, if the bottles be kept in a dark and cool place, laid down and securely closed. In this simple and inexpensive manner we could make sure that the patient gets the exact dose of hydrocyanic acid intended by the prescriber, and we should thus remove one of the greatest and most serious anomalies of practical pharmacy.

Permit me now to offer a few remarks on Liebig's method of determining the strength of hydrocyanic acid. All who are practically familiar with this titrimetric method will, no doubt, be aware that the use of a large excess of KHO or NaHO, will make the result somewhat inaccurate, as in that case too much of the standard solution of $AgNO_3$ will be required to produce a permanent precipitate. The amount of alkali used should be slightly in excess of the quantity required for converting the HCN completely into KCN or NaCN; and if very accurate results are desired for the purpose of comparison, as in the experiments I have quoted, the amount of alkali should be the same in each determination. But the error caused by the addition of too much alkali is small indeed compared to that resulting from the use of an insufficient quantity, and this is a point which, as far as I know, has never been alluded to in chemical literature. Let us bear in mind that Liebig's method is in reality a method for the estimation of KCN, but not of HCN, and that the use of less KHO than is required for the complete conversion of HCN into KCN must of necessity impair the result. The Pharmacopœia tells us to add sufficient NaHO to the acid to render the mixture alkaline, and this is precisely the statement which we find in the various books on chemistry and quantitative analysis. The mere use of sufficient alkali to produce a distinct or even a strong alkaline reaction, may lead an inexperienced analyst into serious errors, for the complete conversion of HCN into KCN or NaCN, cannot be recognised by red litmus paper. I will give some practical instances. In each of the experiments above recorded 5 c.c. of a standard solution of KHO, containing a molecular weight in one litre, were used. Of this solution 3·5 c.c. would be required to convert the 0·0961 grams of HCN present in the 100 c.c. of diluted acid into KCN. But a much smaller quantity would suffice to produce a distinct alkaline reaction; ½ c.c. instead of 3·5, would produce a distinct, 1 c.c. a strong, and 2½ c.c. a very strong alkaline reaction, although in each case the acid would only be partially converted into KCN. A solution of KCN turns red litmus paper blue, even in the presence of a large quantity of free hydrocyanic acid. If the standard solution of $AgNO_3$ is added to such a mixture of KCN and free HCN, a permanent precipitate is obtained as soon as the KCN has been converted into KAg, 2 CN, when the alkaline reaction will be found to have ceased, as the double cyanide has a neutral reaction. The following experiments will show the very erroneous results which may be caused by an insufficient use of alkali.

100 c.c. of the diluted acid, as before, were used for each experiment.

Standard solution of KHO added.	Reaction of the mixture.	Standard solution of $AgNO_3$ required to produce a permanent precipitate.
½ c.c. .	Alkaline	2·4 c.c.
1 c.c. .	Strongly alkaline . .	5·1 "
2½ c.c. .	Very strongly alkaline	12·3 "
3½ c.c. (The exact quantity required for converting the HCN into KCN.)	do.	17·5 "
5 c.c. . (Containing a moderate excess of KHO.)	do.	17·8 "

In the first four experiments the mixture ceased to be alkaline after the addition of the $AgNO_3$; in the fifth it remained alkaline.

The number of c.c. of $AgNO_3$ used in each case corresponds almost exactly to the calculated quantity of KCN present, which clearly shows that the excess of HCN does not affect the result. It is interesting to observe that KCN and HCN can thus be accurately estimated in a mixture of the two.

I do not suppose that experienced analysts would be likely to make such serious mistakes in the determination of hydrocyanic acid as the above experiments show to result from the presence of too little alkali; but I feel sure that the less experienced chemist who is accustomed to work strictly according to the recipe, having implicit confidence in the *modus operandi* prescribed by Liebig, Fresenius, and other eminent analysts, may very probably make such mistakes. Let it therefore be well understood that it is incorrect to use, as the books tell us, sufficient KHO or NaHO to render the mixture distinctly alkaline, or even strongly alkaline, but that the quantity of alkali should somewhat exceed, though only to a moderate extent, the amount required to convert the acid into a cyanide. If at the end of the experiment the mixture does not turn red litmus paper blue, the quantity of alkali used was insufficient, and the result of the analysis will be inaccurate. Should the hydrocyanic acid contain HCl, as is frequently the case, it is evident that the inaccuracy caused by the use of too little alkali would be still increased.

As a rule the chemist will have some idea of the strength of the hydrocyanic acid he is testing; if he has not, a rough experiment with a large excess of KHO will give him one, and he may then calculate the amount of alkali required for an exact determination. An acid containing 2 per cent. or more should be very largely diluted with water in order to obtain a distinct end reaction. Liebig recommends the addition of five to eight volumes of water, but I believe that a much larger quantity (fifteen to twenty volumes) will be found preferable. A slight excess of alkali is useful or even necessary; a very large excess, however, impairs the result. I found that for every 10 c.c. of the solution of KHO which were added in excess of the required quantity, an additional 0·1 c.c. of the solution of $AgNO_3$ was required to produce a permanent precipitate, so that but a slight error will be caused in the result of the analysis by an excess of alkali which is not unreasonably large. The injurious influence of a very large excess of potash is pointed out in several handbooks on quantitative analysis, but no reference is made to the far more serious mistake of using too little alkali in any of the books or journals that have come under my notice.

The Preservation of Diluted Hydrocyanic Acid.

BY JOHN WILLIAMS, F.C.S.

In an important paper by Mr. Towerzey, which was reported in the *Pharmaceutical Journal*, No. 183, page 509, attention was called to the very varying strength of hydrocyanic acid, as found in pharmacy. The author in fact concluded by recommending the disuse of the liquid acid altogether, and suggested the use of a definite salt, such as the double cyanide of zinc and potassium, in its place. To this suggestion there are, however, objections which it is not necessary I should discuss at present. But supposing the liquid acid to be continued in use, it is evidently most important that something should be done, if possible, to preserve and maintain it of a uniform strength, as the present preparation appears not to be reliable after being kept for any length of time.

Now, I have long been aware of the fact that glycerine has the property of preserving hydrosulphuric acid (or sulphuretted hydrogen), and have been in the habit of making such a solution of the gas for some years. If an aqueous solution of the gas is exposed to light, in the course of twenty-four hours decomposition will have occurred, sulphur deposited, and all smell of sulphuretted hydrogen lost, but if to the water 25 to 50 per cent. of glycerine is added, and the liquid then charged with the gas, no change occurs even for months; some I have examined at the end of six months appearing to be as strong as ever.

Bearing this fact in mind, I determined to try if the same thing would happen with the somewhat analogous body—hydrocyanic acid.

A preliminary experiment was made: a 50 per cent. solution of glycerine was charged with 2 per cent. of pure hydrocyanic acid, and at the same time a pure watery solution of the same strength was prepared. At the end of two weeks the solution in pure water was black and spoiled, and had lost the whole of its hydrocyanic acid, while that in the glycerine was colourless, and when tested was still of 2 per cent. strength. This result was so encouraging that I determined to make a series of more careful experiments, to determine not only for how long and to what extent the glycerine should act as a preservative, but also what the effect would be of different proportions of glycerine.

Before proceeding to refer to the results of my experiments, which are shown in the annexed tables, I ought to mention that comparative experiments were made with acid preserved in water in the ordinary way. The makers of hydrocyanic acid, as a rule, add to the acid as sold a small per-centage of a mineral acid—generally hydrochloric acid. Without this addition, as I have already mentioned, the acid will not keep, even for a very short period. In the glycerine solution of the acid employed in my experiments, I need hardly say no mineral acid was added, and I found Price's glycerine better adapted for the purpose than some redistilled of foreign make. The latter caused the acid to assume a slight yellow colour, after a few days, although the strength did not appear to alter. The solution in Price's glycerine remained colourless to the end.

Two samples of hydrocyanic acid, both made exactly 2 per cent. in strength, the one in the usual acidulated water, the other containing 50 per cent. glycerine, were carefully tied over on January 26th, as shown in table 1. The bottles were kept cool, in the dark, and under the most favourable conditions for keeping. On April 26th, or after an interval of three months, they were again tested. The ordinary aqueous acid had become 1·80 per cent.; the acid with glycerine, 1·96. Thus the glycerine had acted almost perfectly, as the loss of $\frac{4}{100}$ths is quite trifling and practically of no importance.

At the same time an experiment shown in table 2 was made under reverse conditions. The samples of acid both made of accurate strength, on January 26th, were purposely left half filled, loosely stoppered, exposed to diffused light, and, in fact, in as unfavourable a condition for good keeping as could reasonably be devised. After an interval of two months the watery acid was found to have fallen to 1·80 per cent., and the glycerine to 1·96 only, but by April 26th, or at three months' interval, the watery acid had gone down to 1·32, while the glycerine had only fallen to 1·84. Thus the glycerine, even under these unfavourable circumstances, had preserved the acid comparatively well.

Table No. 3 shows the results of experiments made with glycerine of various strengths, and also with acid of much higher per-centage than the ordinary medicinal acid of the Pharmacopœia.

The experiments commenced on March 26th. A 50 per cent. solution of glycerine was charged with 8·80 per cent. of hydrocyanic acid—also with 4·12 per cent., which may be taken as representing acid of Scheele's strength.

Also glycerine of 25 per cent. strength was charged with 13·68 per cent. of anhydrous acid, and also with 4·12 per cent. and 2·12 per cent.

Again, a solution of 15 per cent. of glycerine was charged with 16·24 per cent. of anhydrous acid, and also the same strength of glycerine with 2·12 per cent.

These various acids were tested at intervals of one month for three months, and the results are very instructive and interesting.

It will be observed that the weaker strengths of acid, both 2·12 and 4·12, have kept perfectly with all three strengths of glycerine, and show no change of strength during any of the testings. The stronger acids, however, show some change, especially at first. The 13·68 acid becomes 12·40 in a month, while the 16·24 acid becomes 15·20 in a month, 14·64 in two months, at which strength it remained at the end of the experiment. I ought to add that the bottles containing the acids used in these experiments were kept with every possible precaution, to preserve the acid as perfectly as possible.

It appears from these results that there is no advantage in employing a large per-centage of glycerine, 15 per cent. appearing to act as effectively as 50 per cent. I have lately prepared some acid with 20 per cent. glycerine, containing 2 per cent., 4½ per cent., and of the high strength of 26·5 per cent., and shall take a future opportunity of reporting upon them. I think 20 per cent. glycerine would probably be the most convenient proportion for use, supposing it was considered desirable to authorize the use of glycerine for preserving the acid.

It is hardly necessary that I should state that, in performing these experiments, measured—not weighed—quantities of the acids to be tested were taken.

A comparative experiment was made between a white and blue glass bottle. The acid of the same strength preserved by glycerine was kept for two months in diffused daylight. The glycerine had acted equally well in each case—in fact, no difference could be detected, thus proving what has been long known to many, that blue bottles, however useful they may be as distinguishing hydrocyanic acid from other liquids in a dispensary, present no real advantage over white glass in the preservation of the acid.

It is not my wish to offer any opinion as to the propriety, "medically speaking," of introducing glycerine with hydrocyanic acid; my object has simply been to see to what extent the glycerine can be made to act as a preservative of the acid, at any rate for a moderate period. The Pharmacopœia process of testing the acid was in all cases employed. I have to offer my thanks to Mr. Everson, who has performed the many testings required during these experiments with great zeal and care.

TABLE No. 1.

Real Hydrocyanic Acid.	Jan. 26th.	April 26th.
In water	2·00	1·80
In glycerine, 50 per cent.	2·00	1·96

TABLE No. 2.

Real Hydrocyanic Acid.	Jan. 26th.	Mar. 26th.	April 26th.
In water.	2·00	1·80	1·32
In glycerine, 50 per cent.	2·00	1·96	1·84

TABLE No. 3.

	March 26th.	April 26th.	May 26th.	June 26th.
Glycerine, 50 per cent.	8·80	8·56	8·56	8·56
	4·12	4·12	4·12	4·12
Glycerine, 25 per cent.	13·68	12·40	12·40	12·40
	4·12	4·12	4·12	4·12
	2·12	2·12	2·12	2·12
Glycerine, 15 per cent.	16·24	15·20	14·64	14·64
	2·12	2·12	2·12	2·12

The PRESIDENT : After these four very elaborate and able papers, I should imagine the question of hydrocyanic acid has been thoroughly threshed out, except that Mr. Williams has promised us a second report. Mr. Proctor's paper evidences a very great amount of research, such as he always displays. Mr. Siebold seems to me to have hit the right nail on the head, for I have always thought myself that the aqueous hydrocyanic acid of the Pharmacopœia is far too strong. It is a very dangerous thing, and a very little variation makes a vast difference in its effects. I do not see, except on the point of permanency, why we should use so strong an acid. Mr. Siebold finds that actually pure hydrocyanic acid, containing only one-tenth per cent. instead of 2 per cent., keeps remarkably well, and undergoes no change whatever. Mr. Williams seems rather to differ in this respect, and finds the addition of a mineral acid necessary to produce permanency. I fancy myself that a settlement of the question might be arrived at in this way—that the weaker acid of Mr. Siebold's might be employed preserved with the glycerine recommended by Mr. Williams, and that an acid preserved in that way would better meet the wants of pharmacy than the officinal acid now in use. I now ask you to accord a vote of thanks to the four writers of these valuable papers.

The votes of thanks passed unanimously.

Mr. RIMMINGTON : I must say I think, on the whole, there has been more attention paid to this subject than it really merits. I have never been a firm believer in the extraordinary changes that have been set forth, and I think it signifies very little in medicine if you have a change of one, two, or three units in the second figure of decimals. It is not a matter of practical importance ; I may state as a result of my own experience, that I have made hydrocyanic acid in some quantities for many years, and I can keep it three or four years with comparatively little change ; indeed I have some which I had made twenty-five years ago, which is still good. I make a concentrated acid, and dilute it down to the standard of the Pharmacopœia or to Scheele's strength. Then you get the exact quantity, and may keep it for a long time. I quite agree with Mr. Proctor that a corked bottle is better than a stoppered one, because there is a much closer contact between the two surfaces.

The PRESIDENT : I believe myself that ether keeps better in a corked bottle than in one with a stopper.

Mr. RIMMINGTON : I think so, too, and I frequently recommend corked bottles for these very volatile fluids. I hope the gentlemen who have read these papers will not take it that I at all doubt their results ; I am merely speaking from a practical point of view.

Mr. SCHACHT : I thought, as I heard Mr. Proctor's paper being read, I should like, in answer to one observation of his, that the assertion of the variability of this acid is somewhat exaggerated, to give my assurance of the absolute truth of the observations recorded by my then assistant and present partner, Mr. Towerzey. Those experiments, to which allusions have been made, were conducted by us both, and the observations of one were completely verified by those of the other, so that I am perfectly certain that those differences in strength, as reported by him, existed in the samples we examined. Some were taken from my own stock, and some were kindly lent or given us by our neighbours. As such changes do occur, I must confess I am a little surprised to find Mr. Rimmington express an opinion that such differences are of slight importance. One sample, which was positively being used by a gentleman in his dispensary, contained only 0·12 per cent., which was very different from that of another gentleman, whose sample yielded 1·9 per cent., or, as nearly as possible, the correct standard solution. I think the most important contribution to this subject would be any suggestion which would enable us to keep something of the strength of Scheele's. The other part of the business might be easily settled by an occasional dilution of the stock of Scheele's to the strength of the Pharmacopœia, simply putting this into small bottles, keeping them downstairs, and using them one at a time as required. That is one way of easily meeting the difficulty, but we want to be pretty sure that we are not using Scheele's acid, which might happen to be in a stoppered bottle, but has gradually reduced to about half its strength. There, again, I must assure you I am not exaggerating the possibility of this action, for it really happened, that between two occasions of our doing this in my own house, the last being only a week before I left, a change equal to that positively occurred ; what was in the bottle about four weeks ago being of the strength of four per cent., and one week ago it had reduced itself to just one-half. It was kept in our wareroom. and I am sorry to confess it was accidentally left on a high shelf, where it had no business to be, in an uncovered place, where the sun had made the upper stratum of air distinctly hotter than the lower. No doubt, that was a mistake, but it shows the risks to which this preparation is liable. If the addition of glycerine would have the effect of preventing this evaporation—and I suppose its action is simply mechanical—it would be a great boon, because we should then probably be able to conserve our moderate stock with a tolerable certainty of finding it constant in strength. The suggestion which Dr. Tilden made at Bristol seemed to strike every one as a sensible way out of the difficulty, that inasmuch as our general experience showed that the strongest acids most readily parted with a portion of their potentiality by keeping, that if this acid were kept systematically reduced to one-tenth, it would be a strength which would be sufficient for medicinal purposes, and it could be preserved tolerably constant. That struck us as being an extremely sensible suggestion, and I am not surprised to find that Mr. Shenstone finds that strength is less liable to change than any stronger form. Still this little difficulty r mains, that it would be very inconvenient to keep Winchester quarts of hydrocyanic acid instead of smaller parcels. I should like to ask Mr. Williams if he thinks there is any mechanical effect produced by the glycerine. Of course when added to the sulphuretted hydrogen solution it would not be simply a mechanical effect, but in this case I should like to know if it is the mere thickness of the fluid which prevents the evaporation of the vaporous hydrocyanic acid.

Mr. WILLIAMS: That is a very difficult question to answer. I have thought a great deal upon the matter, and I have an idea it is connected with the diffusibility or the non-diffusibility of the menstruum in the air. For instance, glycerine is a non-volatile body, and it may be that it prevents the volatilization of the hydrocyanic acid, which is very volatile. So, with hydrosulphuric acid, it prevents it, or holds it in from its own inclination to diffuse into the air. It struck me that the cherry-laurel water, which is known to keep the acid much better than artificial hydrocyanic acid, probably owes its keeping property to having some essential oil or other body which is not diffusible in air to any extent in the solution. It is also an interesting fact that Mr. Proctor finds the acid to be best preserved by ether, next by alcohol, and least by water, which is exactly the order of the diffusibility of the several vapours in air.

Mr. SQUIRE: I am getting too old, gentlemen, to take part in these discussions as formerly; but I might tell you what I practically found some forty years ago. At that time Scheele's prussic acid was very much in use, and the great objection to it was its loss of power by keeping; hence the 2 per cent. strength was adopted in the Pharmacopœia of 1836. At that time I used to manufacture prussic acid for the greater part of the trade in the city, and I remember Faraday holding up two bottles at the Royal Institution, and saying, "*This* is probably the pure acid, and *this* probably has had hydrochloric acid put into it." It so happened that the one which was colourless was mine, and I went to him afterwards and said, "There is no hydrochloric acid in that at all." He said, "When Davy and I operated on prussic acid we found that hydrochloric acid kept it very well." I said, "Still you must not jump to that conclusion, because I believe, myself, that prussic acid keeps best when perfectly pure, at the strength of 2 per cent." I have had an experience of something like thirty years of prussic acid, and I think if you have it pure and of the strength of 2 per cent., and keep it at a tolerably low temperature, it will keep very well. I bow to recent experience, especially of such men as Mr. Williams, but still I hold my own until I am set right, and, moreover, when we find a thing which has kept its ground since 1836, we should not be too ready to throw it over.

Mr. GILES: We do not intend to throw over this strength, but to introduce it into mixtures in larger volume, and there will be no necessity for altering the Pharmacopœia for that purpose. In the paper this matter is discussed as a chemical question, and as such it appears to me to be settled, and that the difficulty can be met by diluting the solution. As to the question of the difficulty of keeping solutions in the state in which we obtain them, I think it is very easy, and I therefore agree with Mr. Rimmington that, as a practical difficulty, it is much overrated. It appears to me that by moderate care, and by the exercise of common sense, you can easily keep dilute prussic acid within such slight bounds of variation as are unimportant, but I certainly should not keep it in the Winchester quarts, in the form in which I receive it. I always bottle it off into 4 oz. bottles, and it is brought into use in the pharmacy in quantities of twelve drachms at the time. A more interesting question is, How does the glycerine retain the hydrocyanic acid? I think it does that just as we find in other cases volatile or gaseous matters are entangled by a viscid fluid, an illustration of which is the much longer time effervescence is retained in champagne than in soda-water.

Mr. ALLEN: Possibly the difficulty which has been referred to of keeping hydrocyanic acid from volatilizing might be got over by adopting a similar plan to that which I have found very useful in keeping a solution of sulphuretted hydrogen, and in keeping caustic soda away from the air. I keep them in an apparatus fitted like a wash-bottle with two tubes, covered with a layer of paraffin oil, which entirely excludes the atmosphere. When I want any out, I use a small syringe to blow some out through the wash-bottle tube, and if a little cap is kept over the orifice, there is no contact of the air at all, and I cannot imagine that any volatilization could occur in a case of that sort. Sulphuretted hydrogen keeps generally until the bottle is empty, though it gradually deposits some sulphur, I believe by a sort of secondary action. I think the same thing might be done with hydrocyanic acid, and if you do not like to use paraffin oil you might use olive oil, and in that manner keep it entirely from the air. As a pure chemist I have been much interested in Mr. Proctor's paper and his description of the method of preparing hydrocyanic acid from the different cyanides; certainly it seems very unnecessary to take such extreme precaution in preserving it when you can prepare it so readily of any strength you want from cyanide of potassium, or cyanide of zinc and potassium, by the action of tartaric acid. You thus get it very readily and perfectly pure. One other point struck me especially, in Mr. Siebold's paper, and that is the failure of litmus in indicating the real neutrality of the solution, which becomes alkaline with the least quantity of caustic alkali. I was puzzled for some minutes to know how Mr. Siebold ascertained whether he had enough soda there without actually calculating it, and I was very much pleased when he showed us that it was by the alkalinity of the solution on the completion of the operation.

Mr. SIEBOLD: I quite share Mr. Schacht's surprise that some gentlemen are still in doubt as to the great variability of the hydrocyanic acid of the Pharmacopœia. It is evident that either the gentlemen who have so far published their results are not reliable, and their results are false, or else the acid is very variable. If it is so, the question now proposed to the Conference is, I believe, one of the highest importance, considering the powerful nature of hydrocyanic acid as a medicinal agent. I believe everything in our power should be done to remedy the evil which has existed so far, and it is much better we should remedy it by our own experience than that it should be done at the dictation of magistrates, or public analysts, or police inspectors. There are two causes of the deterioration of hydrocyanic acid; one is volatilization, and the other, spontaneous decomposition. The loss by evaporation is, no doubt, the greater. As to the addition of hydrochloric acid to preserve it, opinions have differed at all times; it has been maintained by eminent men that the addition is useful or necessary, whilst others equally eminent have disputed it, not only on theoretical but also on practical grounds. I believe the discrepancy may be explained in this way:—Last year Mr. Rimmington pointed out that hydrocyanic acid acts upon the alkali in the glass of some bottles; that some glass readily yields its alkali to weak acids, and whenever the hydrocyanic acid is put in such a bottle, there cannot be a doubt that the addition of hydrochloric acid is of extreme value, because the alkali would be more readily yielded to hydrochloric acid than to the hydrocyanic acid. I have experimented on bottles of various kinds, and I believe I am justified in saying that the addition of hydrochloric acid is perfectly useless except in the case I have referred to, and my experience agrees with that of Mr. Squire, that the pure acid does not change any more without the hydrochloric acid than with it. But I cannot see any objection to the scheme proposed of storing hydrocyanic acid in a diluted form. I used to make large quantities of cherry laurel water in Hamburg, half a hundredweight at a time, and that was kept in bottles of one pound each; at the end of a year there was no appreciable deterioration in its strength. My experiments now show that the highly diluted form of hydrocyanic acid will keep as well, or almost as well, as the cherry laurel water. Why, then, should it not take the place of the more concentrated form? I do not think myself that the cherry laurel water ought to take its place, but if we have a simple solution in water we are in the same position as using a solution of a common mineral salt in dispensing instead of using the salt itself. For instance, if five minims of the acid are prescribed, and our acid contains $\frac{1}{10}$ per cent., we must use 100 minims. We act in a similar manner continually in the case of bichloride of mercury, sulphate of magnesia, morphia, and other substances.

The PRESIDENT: How would you do in the case of concentrated medicines, where so many drops are ordered to the teaspoonful; the dilute acid would not be applicable to such a case? Pharmacists, however, should not encourage the prescribing of "drops."

Mr. SIEBOLD: I believe this case would rarely occur in the case of hydrocyanic acid. There is another objection as to the dose. In the Pharmacopœia it is from two to eight minims, which is very large when compared with the largest dose permitted to be used in Germany. As I have said, the German Pharmacopœia does not contain hydrocyanic acid, but cherry-laurel water, and the largest dose of that substance allowed to be prescribed is half a drachm, which is equivalent to the smallest dose of the hydrocyanic acid of the British Pharmacopœia. This is certainly a great anomaly, which may be occasioned by this fact, that in fixing the highest dose of eight minims, experiments may have been relied upon which had been made with an acid which had become greatly deteriorated in strength. We continually meet with acids containing less than one per cent., and very seldom does it contain anything like two per cent., unless freshly made. We have no proof whatever that these hospital experiments were not made with a weak acid, and, at any rate, it seems to me a great anomaly that in England the largest dose should be eight minims, whilst in Germany it should be only equivalent to about two. I cannot suppose that there is such a difference in the constitution of Englishmen and Germans as to allow the former to take four times as much as the latter.

THE LEAD-TANNIN PROCESS.

Sir,—In reviewing 'Tea, Coffee, and Cocoa Analysis,' by J. A. Wanklyn, in your issue of to-day, you refer to "Allen's process of titration by means of lead." Permit me to remind you that the method in question was originated and worked out wholly by myself; this acknowledgment accompanying its publication with Mr. Allen's contributions to the *Chemical News*.

FRED. W. FLETCHER, F.C.S.

August 29th, 1874.

WHEAT STARCH.

Sir,—The Pharmacopœia defines "amylum" to be "the starch procured from the seeds of common wheat." As met with in commerce, in powder, such it used formerly to be, but, so far as my experience extends, such it is not now. All which I have had an opportunity of examining microscopically of late, is the starch of maize. On application to an eminent firm of starch manufacturers, I am informed that they cannot supply wheat starch. Can any of your readers inform me where it can be procured?

JOHN ABRAHAM.

Liverpool, 1st September, 1874.

SCIENTIFIC ATHEISM.

Sir,—That the pages of the *Pharmaceutical Journal* are not ordinarily occupied with theological matter will not, I hope, forbid the presence of these few lines in reference to the poison of rank atheism propounded in the elaborate oration of Professor Tyndall with which a late number of your Journal was unfortunately contaminated.

The learned Professor, after proving to his full satisfaction, his own immediate development from the lowest orders of creation with the comforting assurance that "man carries with him the physical texture of his ancestry, as well as the inherited intellect bound up in it," allows further that "the period necessary for completion varies with the race and with the individual." This is a satisfactory admission, inasmuch as it yet holds out a ray of hope that the time may come when the acknowledged ignorance of the learned Professor as regards the origin of life, of which he says, "the whole process of evolution is the manifestation of a Power absolutely inscrutable to the intellect of man," may pass away, and that he may yet be led to see that that Power, of which he knows or desires to know nothing, is none other than the Eternal God, Jehovah, "by whom were all things created that are in heaven, and that are in earth, visible and invisible," of whom, had Professor Tyndall quoted scripture correctly, he would have acknowledged to his auditors, "Canst thou by searching find out God? Canst thou find out the Almighty unto perfection?" and had he turned over the leaves of his Bible a little further to the 38th chapter of the book of Job, and applied the queries therein contained to his own finite intellect, he might have felt constrained to acknowledge with the Psalmist, "The fool hath said in his heart there is no God."

As the antidote to the sad poison of scepticism with which the whole of that Address, abounds, would you allow me to commend to your readers, young and old, the example of the Bereans, of whom we are told that "they received the word with all readiness of mind, and searched the scripture daily whether those things were so, therefore many of them believed," and at the same time to give heed to the exhortation of Paul to Timothy, by "avoiding profane and vain babbling, and opposition of science falsely so called, which some professing have erred concerning the faith."

EDWIN B. VIZER.

September 2nd, 1874.

W. Saville.—The syrups contained in the mixture have a tendency to ferment in the summer. See that they are not fermenting before the mixture is made, and keep it in a cool place below 50° F. if possible. This will be the best means of preventing change.

D. A. Stevenson.—See 'Wanklyn's Water Analysis' and 'Sutton's Volumetric Analysis,' for descriptions of the tests you require.

G. Welborn.—Your communications shall have early attention.

James Mayne.—The smell arising from such factories has sometimes been prevented by ventilating into a tall chimney. (2.) Fresenius, Sutton, or Wanklyn.

An Aspirant for the Major.—We fail to perceive the vagueness you speak of, but if you desire it we will forward your letter to the Board.

Aprons.—We have not had any space that could be spared for your letter, which in reality contains only an "oft told tale," and is not, we think, likely to be conducive to the end you desire.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

CURIOUS CONVERSION OF ALCOHOL INTO ACETATE OF ETHYL BY THE AGENCY OF CRYPTOGAMIC LIFE.

BY F. M. RIMMINGTON.

To those acquainted in any degree with the remarkable power of metamorphosis possessed by some of the microscopic cryptogami, this paper will be of interest. It may probably have been noticed by others that concentrated infusion of quassia is very prone to become acid, but the conversion of alcohol into acetic ether has probably not been before noticed. I assume, both from my own observation and the published experiments of Pouchet and Pasteur, that this transformation has been brought about by the agency of cryptogamic life in the fluid, whether that life was fungoid or otherwise.

My attention was recently drawn to a bottle of concentrated infusion of quassia that I had made myself some months ago, which smelt so strongly of acetate of ethyl that it was rather difficult to resist the belief that some had not been introduced. The fluid was quite clear and bright without any sign of fermentation or other change going on. On pouring off the clear liquor, a very thin stratum of sediment appeared at the bottom of the bottle, looking very like mud.

The circumstance aroused in my mind an interest to know the explanation of this phenomenon, and the inquiry took the following shape:—Lignum quassiæ has often a fusty smell and a corresponding taste; this I attributed to the presence of some form of fungus growth—and most probably the fungus is a penicillium—and, assuming this to be so, the probability is that some of the spores have got into the fluid, and have been slowly and silently effecting the conversion of the alcohol into acetate of ethyl. It is this fact which constitutes the point of interest, for if the alcohol had only become changed into acetic acid, the presence of fungi or anything else would not have been necessary, but the change is of a more complex and delicate character. The amount of acetic acid present is only small, and much diluted, but the odour of the ether is powerful. The next point was to prove the theory I had set up, and I proceeded to examine the sediment microscopically. With a one-fifth objective it looked like granular amorphous matter, mere points, without structure. But sufficient was shown to determine that it was not inert matter, and, on submitting it to the amplifying power of 800 or 900, its nature was clearly and beautifully displayed; it was made up entirely of unicellular organisms, of a somewhat irregular roundish form, about one-third the size of a yeast cell, and having like that one or more nuclei. Besides these cells, were a considerable number of bacteria, or vibrios.

To mycollogists there is another point of interest I will mention; these exceedingly minute bodies, when viewed by reflected light, look opaque, and of a *drab or grey colour*, and are not globular, but flattened on two sides. These flattened sides have raised edges and slightly raised centres, something like the top of a pork pie.

August, 1874.

VEGETABLE POISONS AND THEIR ANTIDOTES.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

(*Continued from page* 1014, *Vol. IV.*)

Cicuta virosa.—This plant being of much less frequent occurrence in this country than *Œnanthe crocata*, cases of poisoning by it are not very common. These two plants are often confounded, on account of the term water-hemlock being erroneously applied to both of them. For this reason, it is difficult to ascertain, in several recorded instances of poisoning by water-hemlock, to which plant the symptoms which were produced should be attributed.

The two plants may be readily distinguished thus:—

Cicuta virosa (water-hemlock or cowbane) has globular fruit, narrow lanceolate, distinctly serrate leaflets, a præmorse root, which is hollow within, with transverse partitions.

Œnanthe crocata (hemlock water dropwort) has narrow, cylindrical fruit, surmounted with two styles, of nearly the same length as the fruit; the leaflets are wedge-shaped, with two or three teeth at the apex, and the root consists of four or five fusiform tubercules.

Cicuta virosa is said to be fatal to horned cattle and dogs, but to be eaten with impunity by goats and sheep. In the few cases of poisoning by this plant, in which the symptoms have been observed, they appear to have been as follows:—Giddiness, bloated face, burning pain in the stomach, spasmodic breathing, intermittent pulse, at times feeble and at others tumultuous, coldness of surface, dilated pupils, and coma. The occurrence of tetanic spasms is also very marked, and the brain seems to be affected no less than the spinal cord.

Death has occurred, in a few cases, in half an hour, but in others not until sixteen hours after taking the poison. Paralysis of the muscles of respiration appears to be the immediate cause of death.

Cases of Recovery.—The following case occurred in Germany:*—Four children ate a large root; one of them died almost immediately, but the other three recovered after having been given milk, a sulphate of zinc emetic and decoction of nutgalls; external stimulants were also used. The recovery was attributed to the decoction of nutgalls, but the treatment was so varied that the conclusion is, perhaps, open to discussion.

In another case† some boys having eaten the root of water-hemlock, all recovered by the administration of an emetic of mustard and warm water, except two of them, to whom it was found impossible to administer an emetic on account of tetanic spasms.

Antidotes.—In a case of partial recovery, the amelioration was marked by contraction of the pupils of the eyes.‡ In the cases of recovery on record, early vomiting was induced, probably before much of the poison was absorbed into the circulation.§ No real antidote is known, nor is it possible to suggest a probable one, until more accurate knowledge of the physiological action of this group of poisons has been obtained.

The best treatment is to administer, as speedily as possible, an emetic of mustard and water, followed by milk and purgatives. Probably the cautious inhalation of chloroform might be useful in some cases to relax the tetanic spasms, and thus permit the administration of an emetic. Judging from the pupils being dilated, and the occasional presence of delirium, opium might possibly prove of service.

Œnanthe crocata.—This is one of the commonest

* *American Journal of Pharmacy*, vol. ix. (2), p. 153.
† *Pharm. Journ.*, vol. 2 (3), p. 1063.
‡ 'Taylor on Poisons,' p. 810.
§ *Lancet*, Sept. 16th, 1871, p. 396.

of the British poisonous Umbelliferæ, and the most virulent in its action.

It would, however, appear to vary in strength in different specimens, for Dr. Christison states that *Œnanthe crocata* and *Cicuta virosa* were innocuous when grown near Edinburgh;* it has been also stated that roots containing a yellow juice are more poisonous than those with a colourless juice. Stephenson and Churchill state that the root contains a milky juice which turns yellow on exposure to the air. Probably the colour of the juice depends upon the age of the plant. It would be interesting, however, to determine this point, and to know whether the strength varies in different parts of the plant, as in conium.

The symptoms of poisoning generally commence with convulsions, and insensibility soon follows. Other symptoms are bloated countenance, dilated pupils, great prostration, imperceptible pulse, and sometimes tetanic spasms, death occurring in half an hour to two hours† after taking the poison.

Cases of Recovery.—In one case in which the roots dug up in March were boiled and eaten by a woman, her husband, and two children, recovery took place by the use of emetics.‡ Orfila relates that out of thirty-six soldiers who partook of the root, only one died; the rest, having vomited freely, recovered.§

Dr. Kane|| relates full particulars of a case of recovery from poisoning by a plant which might have been either *Œnanthe crocata* or *Œthusa cynapium*, as both grew in the same locality. In this case chloroform was administered to relax the rigidity of the muscles; and emetics of mustard and water and antimonial wine having failed, an enema of turpentine was administered, as well as thirty drops by the mouth in milk. This treatment, together with cautiously repeated doses of whisky as a stimulant, was followed by perfect recovery.

How far the recovery in the last case was due to the use of chloroform, or to the fact that the child vomited before the symptoms came on, it is difficult to say; but, judging from the majority of cases in which recovery has taken place, the most important thing to do seems to be to produce vomiting as speedily as possible; possibly for this purpose the subcutaneous injection of apomorphia might prove more effectual and speedy than the internal use of an emetic. The use of *chloroform*, *chloral*, or *gelsemium*, to relax muscular rigidity, and thus prevent the exhaustive action of the poison upon the nervous system, and the subcutaneous injection of *liquor ammoniæ* as a stimulant, are perhaps the best antidotes that could be suggested until more accurate knowledge is obtained concerning the physiological action of this plant.

Œthusa Cynapium.—The leaves of this plant somewhat resemble parsley in appearance, but are darker in colour, and have more finely-cut leaflets.¶ It has occasionally been mistaken for that plant, and thus caused death. It also somewhat resembles hemlock, but may be distinguished from it by the three long pendent bracts beneath each partial umbel. A case of poisoning which occurred through mistaking this plant for hemlock is recorded in Stephenson and Churchill's 'Medical Botany.'**

* *Pharm. Journ.* (2), vol. iii., p. 432.
† *Pharm. Journ.* (3), vol. i., p. 110.
‡ 'Taylor on Poisons,' p. 811.
§ 'Orfila on Poisons,' vol. v., p. 67.
|| *Medical Times and Gazette*, 1869, vol. ii., p. 379.
¶ 'Orfila,' vol. ii., p. 251.
** Vol. i., No. 8.

The symptoms produced closely resemble those of poisoning by *Œnanthe crocata*—bloated face, heat in the stomach, shortness of breath, muscular rigidity, nervous tremors, numbness of limbs, and occasionally delirium. Death usually takes place in from one to twenty-four hours, and paralysis of the respiratory muscles appears to be the immediate cause of death.

Cases of Recovery.—In two cases mentioned by Taylor,* the recovery appears to have been due to the plant having been eaten on a full stomach, and to vomiting having taken place early. In other cases, the recovery seems also to have been due to speedy evacuation of the stomach.

Antidotes.—The symptoms are so similar to those produced by *Œnanthe crocata* that the same treatment is probably the best that could be suggested.

Observations.—It will be seen that the symptoms produced by these three plants are very similar. So far as their physiological effects are known, they appear to be these: the secretory power of the liver is arrested, and the sensibility of the intestinal canal much depressed, while the vessels of the brain become turgid with blood. The use of such purgatives as calomel and podophyllin would therefore seem to be indicated, together with the use of some powerful stimulant, such as Liq. Ammoniæ, injected hypodermically, to restore the equality of the circulation.

Our knowledge of the alkaloids of these three plants is in a most unsatisfactory state. *Œthusa* is said to contain conia or an analogous principle, as well as cynapine, and *Cicuta* probably contains a volatile alkaloïd, although some have failed to detect it; for the leaves, when dried, are stated to be without poisonous properties.†

Œnanthe crocata has not, that I am aware, been analysed. Yet it is probable that these plants may, in small doses, possess useful medical properties.

An infusion of the leaves and the expressed juice of *Œnanthe crocata* have been used in lepra and ichthyosis, and it is said with success,‡ and in Westmoreland a poultice of the leaves is used to heal ulcers in the feet of horned cattle.§

FREEZING MIXTURES.||

BY M. BERTHELOT.

The researches of the author upon the crystallized hydrates of sulphuric acid have supplied him with the data necessary for calculating the lowering of temperature which these hydrates develope when mixed with snow or powdered ice. Some of these details he has discussed in their relation to freezing mixtures in general in a paper from which the following is taken. It may be as well to notice that he uses the old notation (C = 6, O = 8) throughout.

The thermic effect which is produced when snow is mixed with solid crystallized bihydrated sulphuric acid is the sum of three effects, viz.—the fusion of the acid, which absorbs heat; the fusion of the snow, which also absorbs heat; and the combination of the two liquids, which disengages heat. Thus, for example, with three parts of acid and eight parts of water—that is to say, in equi-

* 'Taylor on Poisons,' p. 815.
† 'Woodville's Medical Botany,' vol. i., p. 96.
‡ *Philosophical Transactions*, vol. lxii.
§ 'Stephenson and Churchill's Medical Botany,' vol. i., No. 35.
|| Abstract of a paper read before the French Academy (*Comptes-Rendus*, vol. lxxviii., p. 1173).

valents, SO_4H, HO (58 grams) and 17 HO (153 grams)—both bodies solid and taken at 0°—

	Heat units.
The melting of SO_4H, HO absorbs, according to the author's experiment	— 1,840
The melting of 17 HO, according to M. Desains, absorbs	—12,155
Upon the union of SO_4H, HO with 17 HO the two liquid bodies disengage.	+ 4,900
	— 9,015

This is the quantity of heat absorbed by 211 grams of the mixture. To ascertain the lowering of the temperature, it is sufficient to divide it by the product of the weight of the mixture and its specific heat. Thus—

$$-9{,}015 \div (211 \times 0{\cdot}813 =)\ 171{\cdot}5 = -52^{\circ}{\cdot}6.$$

If the operation is conducted at a lower initial temperature and with ingredients previously cooled, a calculation based upon the formula which expresses the variation of the heat of reactions with the temperature,* shows that the heat absorbed increases by the variation of the heat of combination = — (0·1715 — 0·089 heat units), or about $\frac{1}{110}$ for each degree less in the initial temperature. Commencing at —20°, the additional lowering would be 62°, and so on, increasing but slowly, in proportion as the initial temperature is lower.

If the bihydrated sulphuric acid, in the liquid state, be employed at 0°, the heat absorbed would be only —7,155 heat units, and the lowering —42°. Commencing at —20°, it would be —50°, which would lead to a final temperature of —70°.

Lastly the monhydrated sulphuric acid liquid SO_4H, in the presence of 18 HO, solid, starting at zero, will absorb only 4·025 heat units, producing —23°·7.

It will thus appear that the absorption of heat and lowering of temperature vary a little with the initial temperature, the final temperature being increasingly lower in proportion as the operation is commenced with a mixture previously more cooled. The only limit is the freezing point of the mixture of water and sulphuric acid, but that point is excessively low.

It has been found by previous authors that a cold of 32°·5 can be obtained with three parts of snow and one part of liquid sulphuric acid containing one-fifth of its weight of additional water. An analogous mixture, with its ingredients previously cooled to —7° would lower the temperature to —51°. From the eighteenth century, mercury has been congealed with similar mixtures of snow and sulphuric acid. MM. Pierre and Puchot, in recent experiments, have obtained only —26° with a mixture of three parts of crystallized bihydrate and eight parts of pounded ice.

All these numbers are below those deduced by theory, but it is necessary to observe that the heat is diffused between the mixed substances and their surroundings; radiation leads to considerable loss. Besides, and this is the principal cause of the differences observed, one portion of the ice remains solid, and diminishes proportionally the cold obtained. Snow is preferable to ice in this respect.

During last century, it was principally by means of mixtures of dilute nitric acid and ice that operations for the solidification of mercury were conducted, a problem that greatly interested the chemists of former days. The following is the calculation relative to one of the most frequently employed of these mixtures. With a mixture of nitric acid ($NO_6H + 3\,HO$) and twice its weight of snow ($10\,H_2O_2$), the heat absorbed, starting at 0°, is 11·000 heat units, the lowering of temperature —56°.

Generally, the artificial production of cold depends upon the following artifices, either alone or combined in the same operation:—

1. Transformation of a liquid or a solid into gas (vaporization of ether or sulphurous acid, treatment of a bicarbonate with an acid).

* *Annales de Chimie et de Physique* [4], vol. vi. p. 304.

2. Liquefaction of a solid in contact with a liquid (solution of salts) or with another solid (crystallized sulphuric acid and ice, ice and chloride of calcium, etc.).

3. Chemical reaction effected in the midst of a liquid with the formation of substances the solution of which would absorb more heat than that of the primitive compounds (solution of an alkaline acetate, and solution of tartaric acid, according to the author's experiments); or the formation of bodies that gradually decompose in the liquid, such as the salts of feeble acids (carbonate of ammonia, formed by a mixture of solution of an alkaline carbonate and a solution of sulphate or nitrate of ammonia), the acids, salts, etc.

4. Whatever be the reaction employed, the lowering of the temperature (t—t_1) may be calculated from a knowledge of the heat absorbed in the reaction (Qt), the weight of the substances, between which it is distributed (p, p'), and their respective specific heats (c, c').

$$t - t_1 = \frac{Qt}{\Sigma pc}.$$

This reduction changes slowly with the initial temperature (t) as long as Qt is considerable and the specific heats can be regarded as constant. But it is limited by the freezing points of the saline solutions, which do not admit of the indefinite reduction of the temperature.

It should be observed that no other system is capable of producing a refrigeration comparable to that produced by the integral transformation of a liquid into gas, as may be ascertained by calculation. For example, ether in vaporizing produces a lowering of temperature theoretically of —192° C.; sulphide of carbon of —530° C.; liquefied ammonia of —460° C.; and the protoxide of nitrogen of —440° C. But the refrigeration is arrested at points far short of these; which arises from the tension of the vapour of the liquid that is changed into gas becoming so feeble that the cold produced in a given time is compensated by the ambient radiation, by which it becomes reheated. In fact, the cold produced by the vaporization of a liquid, even in a vacuum, scarcely allows of the lowering of the temperature more than 60° to 80° C. below the boiling point of such liquid under atmospheric pressure; hitherto only in a single case, the congelation of water, has 100° been exceeded. However this may be, these figures, both theoretical and practical, show that no process of refrigeration is comparable to vaporization, and the same result has been arrived at industrially. But M. Berthelot is of opinion that a better directed employment of the sources of cold, which theory indicates to be at our disposal in liquefied gases, should make it possible to go much lower than has been done at present, and to approach nearer to that actual zero which appears to be about — 273° C.

CRYSTALLIZED DIGITALIN.*

BY M. NATIVELLE.

The process described by the author in his former paper on the preparation of crystallized digitalin,† is one that presents considerable difficulties, and, in unpractised hands, has frequently only yielded negative results. Sensible of this, M. Nativelle has during the past two years sought to discover a satisfactory modification of it, and he has recently communicated to the Academy of Medicine and the Society of Pharmacy in Paris the details of a process by which he states the new substance can be obtained inexpensively in considerable quantity, and absolutely pure. The modification consists chiefly in the separation of the digitalin from the digitin by means of chloroform, and afterwards removing the yellow oily substance,‡ which

* Abstract of a paper in the *Journal de Pharmacie et de Chimie* [4], vol. xx., p. 81.

† See *Pharm. Journ* [3], vol. ii., p. 865.

‡ This substance consists of a thick fatty oil, having the peculiar odour of amorphous digitalin, and a yellow colouring substance which is reddened by alkalies.

accompanies the digitalin and retards its crystallization, by treatment with ether.*

Before describing the process, the author gives some details as to the comparative value, for the purpose, of digitalis in its different stages of growth. The plant of the first year, especially that which is collected too young, is not rich in crystallizable digitalin; fleshy and full of juice, it abounds in digitalein and extractive matter. Digitin, a crystallizable but inert substance, which must not be confounded with the active principle, is present in it as in the older plant. The plant of the second year's growth, collected just when the first flowers appear, using only the leaves from which the petioles have been removed, is what the author has found most suitable, both for the preparation of digitalin and for use in the natural state.

M. Nativelle's experiments confirm the observations of previous authors as to the comparative value of different parts of the plant. He has found that the root, stems, petioles, and nerves contain only a very small proportion of the active crystallizable principle, and in operating upon equal quantities of the petioles and of the green portion of the same leaves from which the petioles had been removed, he obtained five times as much crystallized digitalin from the latter as from the former. Thus selected, the ordinary yield of digitalin is one part in one thousand, but from the mature plant collected in the Vosges, he has obtained 12 centigrams to the 100 grams.

The following are the details of the process :—

Digitalis Leaves (Vosges) in moderately fine powder	1000 grams.
Neutral Plumbic Acetate	250 „
Distilled Water	1000 „

The lead salt is dissolved in the cold water, the powder added and thoroughly mixed, then passed through a sieve, and left in contact during twenty-four hours, taking care to stir it together from time to time. The mixture is next exhausted in a displacement apparatus with 50° alcohol until it ceases to impart any bitterness. To this liquor is added 40 grams of bicarbonate of soda dissolved to saturation in cold water. The effervescence having terminated, the spirit is distilled off, and the remaining liquor evaporated in a water-bath to about 2000 grams; it is then allowed to cool and diluted with six times its weight of water. Two or three days afterwards the clear liquor is decanted by means of a syphon, and the precipitate drained and pressed.

The extractive liquor being thus removed, the precipitate weighs about 100 grams. This is suspended in about 1000 grams of 80° alcohol, and the whole passed through a fine metallic or silken sieve. The resulting turbid liquor is then heated to ebullition, and ten grams of neutral plumbic acetate added to it; the heat is continued for a few minutes and the liquor filtered through paper. Upon the deposit in the filter alcohol is poured, to remove any liquor it may retain, and it is then pressed. To the liquor is added 50 grams of quite neutral vegetable charcoal, in fine powder, and it is then distilled. The charcoal remaining is heated for some time in a water-bath to drive off any alcohol it may retain, then allowed to cool, and put to drain upon the sieve used for the separation of the precipitate, and thus separated from the coloured liquor. This charcoal is dried in a stove, and exhausted by displacement with chloroform until the latter passes through colourless.† This liquor is distilled to dryness, and the residue is crude digitalin, mixed with a pitchy substance and oil. It is dissolved with heat in 100 grams of 90° alcohol, one gram of neutral plumbic acid dissolved in a little water is added, and ten grams of washed animal charcoal in fine grains without powder; after boiling for ten minutes it is allowed to cool. After the liquor has settled, it is filtered through a glass cylinder, furnished with a tight cotton plug; it passes quickly and clear, and to the residue the deposit is added, and the whole exhausted of all bitterness by alcohol, which is afterwards distilled. The digitalin appears in a crystalline grumous mass, contaminated by the coloured oil. It is separated from the small quantity of aqueous liquor in which it is found, then dissolved with heat in ten grams of 90° alcohol, five grams of rectified sulphuric ether, and fifteen grams of distilled water added, and the whole shaken together in a stoppered vessel. Two layers are formed: the upper is coloured and consists of ether which has taken up the fat oil; the lower is colourless and contains the digitalin, which, being set free, quickly crystallizes. Two days afterwards the whole is poured into a small cylinder furnished with a tight cotton plug; the mother liquor passes through, and then the coloured layer, what remains of the latter adhering to the crystals being washed off by a little ether.*

This first crystallization of digitalin is slightly coloured. To obtain it perfectly white, two purifications are necessary, but previously a treatment with chloroform is indispensable to separate about one-tenth its weight of digitin, which it still retains. The digitalin well dried, is, therefore, reduced to a fine powder† and dissolved in twenty parts of chloroform, and the solution filtered through a tight plug of cotton. The clear liquor which passes is distilled to dryness, and a little alcohol then added for the purpose of removing by evaporation the last traces of chloroform.

This digitalin is dissolved in 30 grams of 90° alcohol, 5 grams of washed animal charcoal in granules added, the liquor boiled during ten minutes and filtered, the charcoal exhausted as before, and finally the product is distilled; the digitalin crystallizes on the sides of the vessel, but it is still coloured. To obtain it white, it is again dissolved with heat in 8 grams of 90° alcohol, 4 grams of ether, and 8 grams of water added, and the whole shaken together in a close vessel. After being exposed during a night, nearly the whole of the digitalin is deposited in small white acicular groups; that which still retains colouring matter (about one-fifth) remains in the mother liquor, from which, however, it can be purified by further operation with very little loss. The whole is poured into a cylinder as before described, and the crystals washed with ether.

The digitalin so obtained is white and pure; but, by a further treatment, it may be obtained still more beautifully and perfectly crystallized. For that, it is dissolved in twenty-five parts of 93° alcohol, 5 parts of black added and treated as before. The liquor obtained is colourless and is distilled until reduced to ten parts; the heat is then raised to boiling temperature, to dissolve a little digitalin that is deposited, and poured upon a slightly-heated glass, supported under a bell-glass, and covered with a disk. The crystals then form slowly in groups or bundles of very white slender brilliant needles. When they no longer appear to augment, the disk is removed, and the alcohol being nearly evaporated, the crystals are dried in the air upon folds of paper.

---

* Carbon bisulphide may also be used for this purpose, but it offers certain inconveniences. The author, however, used it in the preparation of some very fine specimens of crystallized digitalin, which were exhibited at Vienna last year, and have since been presented to the Academy of Medicine.

† The residue contains digitin. To separate it the chloroform is recovered by distillation and the residue exhausted with boiling 80° alcohol, the liquor filtered, half the alcohol removed by distillation, and all the remainder left to crystallize. The mother liquor retains a little digitalin, which may be recovered by evaporating to dryness and treating with chloroform. The digitin is purified by dissolving it in boiling alcohol, decolorizing with charcoal in grains, filtering, and allowing to crystallize. It appears in very white, fine, nacreous needles, totally devoid of taste.

* This mother liquor retains some digitalin and the fixed oil. These can be separated one from the other by distilling off the ether and alcohol, and agitating the residue with carbon bisulphide, which dissolves the oil only. The digitalin can be recovered by dissolving it to saturation in hot alcohol, and adding to the liquor half its volume of ether and a little water to determine its crystallization.

† The pulverization of digitalin is dangerous; its inspiration may be avoided by putting cotton in the nostrils.

A NEW SEAT OF PHARMACEUTICAL EDUCATION IN GERMANY.

UNDER the French domination in Strassburg, there was an École Supérieure de Pharmacie the establishment of which had been ordered as early as 1803, by the same law which likewise instituted the Schools of Pharmacy of Paris and Montpellier. The Strassburg school, however, was nothing more than a board of examination until 1840, when all the three schools of pharmacy were incorporated by law in the *Université de France*, which includes all the scientific institutions, the *Faculté*, as they are termed, of the whole country. Some years previous to this, the professors of the Strassburg school had delivered some lectures, yet it was only in 1841 that they obtained a building for opening a laboratory. There were then six professors, teaching physics, materia medica, natural history, inorganic chemistry, organic chemistry, toxicology, botany, pharmacy, and practical and analytical chemistry in the laboratory. It is to be regretted that there is no history of the school of Strassburg, which for thirty years had certainly a great, and we may say, useful influence on the progress of pharmacy in the eastern parts of France.

After the war, the professors left for Nancy, where the French Government established a new School of Pharmacy; while in Strassburg five pharmaciens of the city were provisionally entrusted by the German authorities with the lectures of the old school, which they opened in November, 1871.

But the Chancellor of the German Empire abolished the five *Facultés* hitherto existing at Strassburg and also the School of Pharmacy; and instituted, by a law of April 28th, 1872, the *University*, instead of the six above-named scientific institutions. German universities, at least the more considerable among them, are expected to comprehend all branches of science, so that, in German eyes, a school or college exclusively devoted to pharmacy is by no means desirable either from a professional or a scientific point of view. This feeling is in contradiction with English, American, or French ideas, yet it is strongly prevalent in Germany. In fact no school of pharmacy is in existence in that country, and nobody seems to have cared for the abolition of the school of Strassburg, except the pharmaciens of the annexed country, who were unable to save it. The examinations and lectures were stopped on 30th September, 1872.

Yet it must not be supposed for a moment that by these measures the imperial government sacrificed the interests, either practical or scientific, of pharmacy. The fine building, the garden, and the collections of the French establishment continued to be devoted to the same purposes, and were, in the beginning of 1873, placed under the superintendence of Professor FLÜCKIGER, of Berne, who was appointed *Professor ordinarius* in the University, and especially charged with the pharmaceutical lectures. He also was soon appointed to preside over the *Prufungs-commission*, or Board of Examinations, similar boards being in activity in all the universities of Germany.

As to pharmaceutical education, whether practical or scientific, in the University of Strassburg, it is not based on any programme or plan whatever; all is simply regulated by the examinations. The students are free to choose the university and the lectures which they prefer. They are not, however, admitted to the examinations unless they prove to have devoted due time to their scientific acquirements in a German university.

We need scarcely add that all students, whether German or not, are freely admitted to both the lectures and the laboratory, and the fees are very moderate. English students desirous of pursuing their education in Germany, would, we are assured, meet with a very kind reception in Strassburg, whether they came for a short stay, or to enter on a full course of study. German is the language in prevalent use, but French is universally understood, and English by at least the professor who is at the head of the pharmaceutical department.

As to the lectures and practical instruction which will commence in November, 1874, those of particular interest to pharmaceutists are the following:—

Inorganic Chemistry, Professor Baeyer; Laboratory, Professor Baeyer and Professor Rose; Industrial Chemistry, Professor Rose; Analytical Chemistry, Professor Rose; Toxicology and Forsenic Chemistry, Professor Hoppe-Seyler; Action and Application of the more important Medicines, Professor Schmiedberg; Materia Medica, including important Vegetable Substances used in the Arts, Professor Flückiger; Laboratory for Pharmaceutical Research and Practical Demonstrations in Materia Medica, Professor Flückiger; Anatomy of Plants, Professor de Barry; Practical Botanical Researches, Professor de Barry; Algæ and Fungi, Professor de Barry; General Botany, Professor Count Solms Lanbach; Musci, Filices, Professor Count Solms Lanbach; Magnetism, Electricity and Heat, Professor Kundt; Optics, Professor Kundt; Practical Researches in Physics, Professor Kundt; Introduction to Practical Physics, Dr. Röntgen; Physical Chemistry, especially Gasometry, Dr. Röntgen; Theory of Heat and Capillarity, Professor Warburg; Palæontology, Professor Benecke; Practical Geology and Palæontology, Professor Benecke; Petrography, Professor Rosenbush; Practical Examination of Rocks, Professor Rosenbush; Mineralogy, Crystallography, Practical and Theoretical, Professor Groth; Introduction to Geology, Professor Schimper; Palæontology of Plants, Professor Schimper; Zoology, Dr. Götte.

It will be seen from the above, that the German Government of Alsace-Lorraine, while abolishing the ancient school of pharmacy, have largely replaced it by all the means of a thorough scientific education, which they liberally offer to pharmaceutical as well as to other students.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS' AND APPRENTICES' ASSOCIATION.

The first meeting of the session was held on Thursday, August 13th, when refreshments were provided, and the following Inaugural Address was delivered by the President, Mr. W. B. Clark :—

Gentlemen,—In opening the business of this session with a short Presidential Address, I propose to confine myself chiefly to a brief review of the past history and present prospects of this Association. In the course of my remarks, I shall endeavour to trace out the elements of its past success, noticing also the dangers that threatened to swamp it, glancing also at those causes which, in my estimation, have stunted its results; trusting from reflection upon these to be able to draw a chart (even if a poor one), which will guide us safely through the half-year upon which we are now entering, so that at the close of the session the Association may consist of a greater number of real students than have ever been enrolled before.

In the beginning of the year 1869, Messrs. E. H. Butter and H. Cooper first conceived the design of banding those employed in the Drug Trade in Leicester together, for the purpose of helping them in their preparation for the Pharmaceutical Examinations. Upon calling upon a few of the assistants, they speedily found sufficient encouragement to lead them to arrange for an early meeting. At this meeting, a committee was formed, with Mr. E. H. Butter as President, which guided the affairs of the young Society over its first half-year. During this season of its existence, its difficulties were numerous, such as scarcity of gentlemen who would deliver lectures, the want of a suitable room, the lack of pecuniary resources, and finally the fact that but very few of its members had passed the Preliminary examination. At the close of the half-year, progress had been made, for we find, from the report, that four principals had assisted the Association with their approval of its objects, as well as by annual subscriptions, and that, after paying all expenses, the Treasurer had a balance in hand of £2 9*s.* 10*d.* Perhaps the chief reason of the success of the Society at this, its early stage of existence, consisted in the fact that almost every member had some examination to pass, and was firmly persuaded that the Association would provide him powerful help.

The next session, with Mr. John Young as President, found the Association growing stronger, having obtained a suitable room for its meetings, at St. George Street; the principals also testified their approval of the Society by sustaining its financial affairs. The attendance also of the members was very good, a great improvement having taken place among the juniors, owing to the fact that the committee had started a class specially for their instruction, but still we notice that at the end of this session no member had during the year passed any one of the examinations of the Pharmaceutical Society. Entering upon the third half-year of the existence of the Association, we find again Mr. Young elected President, with Mr. W. E. Hill as Vice. And now we find that the first twelve months had not been wasted by the members, for we note that three Minor, two Modified, and six Preliminary examinations are passed in the following half-year. In spite of all this, the success of the Association was but partial, for we find that a most serious falling-off of the number of members was experienced; this was occasioned partly by some little jealousy springing up among a few of the members, and partly perhaps by the fact that a great number of the younger members had given their spare time almost solely to the preparation for the Preliminary examination. Again, the financial affairs of the Society were in a safe condition. And now with the same two gentlemen as leaders, we find the business of the Association being transacted at much more suitable rooms, in Halford Street, which have been found very convenient to the present date. We notice again the Association with diminishing numbers, in fact, the smallest number of members since its establishment, only having eleven assistants, with a like number of apprentices, upon its books. But, nevertheless, we had two members pass the Major, one the Minor, and one the Modified examination. I will here quote from the remarks of the committee concerning the supper :—"That it is greatly conducive to that good feeling among principals and their assistants which for the interests of future pharmacy it is desirable to maintain."

At the commencement of the fifth session we find Mr. W. B. Clark, President, and Mr. H. Cooper, Vice-President. In the first place, there was an increase in the number of members; secondly, one member passed the Minor and two the Preliminary; thirdly, we find the apprentices of the Association being ably instructed for the Preliminary, by Mr. N. S. Grigsby. We read also of an impetus being given to the Association by a grant from the London Society towards the formation of a library, etc. At the next general meeting of members, we have Mr. W. E. Hill appointed as President, with Mr. T. Wright, as Vice-President. Under the leadership of these two gentlemen the Association made rapid advances, improving very much the number upon the books; possibly this was the most prosperous period of the existence of the Society since its formation, although no examinations were passed. In my opinion, this elasticity was accounted for by the following facts: firstly, that the two gentlemen at the head of the the Association were very popular, and testified to the interest they felt by the frequency of their attendance; secondly, the classes conducted by Messrs. Hill, Wright, Clark, and Thirlby were suited to the needs of the members, whilst a series of instructive lectures were delivered by Messrs. Cox, Young, Burton, and Weaver. The seventh half-year started with Mr. W. Bradley for President, and Mr. S. H. Cadoux as Vice-President, and again there was a very flourishing session, for again there was a large number of members enrolled upon the books, and what is of much more importance attending very frequently. We find also four members passing the Preliminary and the Minor. Before passing on, I wish to pay a tribute of respect to Mr. Bradley for the painstaking manner in which he helped to forward the Association during the time he was connected with it. And now having lost, for a time at least, Messrs. Hill, Wright, and Bradley by removal to other spheres of labour, the Association found its chief officers in Mr. Cadoux as President, and Mr. W. B. Clark as Vice-President. A successful half-year was again passed; the papers which were usually read at about monthly intervals were discontinued for a time, some difficulty having been experienced in finding gentlemen competent enough and willing to undertake them. Again we notice the President devoting much time and energy to the interests of the Association, the botany class being a great success. The ninth session was passed under the presidency of Mr. N. Thirlby, and again the Society makes headway. It increases in number, the attendance is even more regular, and it is assisted by a grant of ten pounds from the Pharmaceutical Society towards the purchase of a materia medica cabinet.

A well-devised cabinet having been built, and carefully filled with specimens, has been of the greatest use to the members. At the next general meeting, Mr. J. Wright was elected to preside, with Mr. S. H. Cadoux as Vice-President. We again find the classes fairly attended, but at this period some little harm was done to the Society by a few of the members deeming themselves slightly injured by others, indulging in personal feelings, and thereby endangering the general good. But wise action upon the part of the Committee, coupled with forbearance upon the part of the disputants, speedily restored order. And now we find ourselves at the beginning of our last half-year, with the old President re-elected. I will not trouble you with many remarks, the printed report being just in your hands. Suffice it to say that in spite of the largest number of members we have ever had, the average attendance at each class has been below the mark; in other respects a most satisfactory session has been passed.

Having now glanced at the work of the Association since its rise, I wish to bear testimony to the way in which your committee have discharged their numerous duties, for in my opinion the well-being of the Association has depended very largely upon the official arrangements these gentlemen have made. Having had some opportunity of noticing, I will add that when unanimity has not prevailed, the minority have heartily aided in carrying into effect the wishes of the majority. One of the causes of success I think we find in the fact that our presidents have usually been those most eminent for their pharmaceutical knowledge, and have been most popular; in almost every case attending a large percentage of the meetings. In selecting our committees, the members have most wisely remembered that business skill and tact are oftentimes of equal value with technical knowledge; the one may provide the weapons, while the other will furnish the strong arms to use them. And now to turn to the most important source of the success that has attended us; it has been, we think, in the fact that the Association has always had among its members those who have made it a point to be present at most of the meetings, not always to obtain additions to their own information, so much as to support, by their presence and remarks, the interest of the less warm-hearted. Much good has also resulted from the great care shown by both juniors and seniors in avoiding, as subjects of conversation, the affairs of their principals; in our esteem, too much praise cannot be given on this account. The continual hearty support of the honorary members is the best proof of their opinion.

I wish also to allude to the prizes which have been occasionally given; the good effect of this has been evident in spite of the difficulties that must always attend the offering of rewards to small classes, when no easy means exist for the testing of the progress of the members during a given time; for let it be remembered that our prizes should not fall to the most advanced students, but to those who, by constant, steady attention, have gained, during the half-year, the largest accessions to their previous knowledge.

And now, gentlemen, it remains for us to look at the causes that may affect us in the future. In the first place it will be plain to you all that higher qualifications will be necessary for the future pharmacist than have been demanded in the past; not long will the nation be satisfied with unpassed men to dispense their prescriptions. The Council of the Pharmaceutical Society have already wisely decided that a three years' apprenticeship qualification shall be demanded of candidates for the Minor. You ask how will these arrangements affect our Association? I reply (bearing in mind the fact that at many establishments only apprentices who have passed the Preliminary are admitted), that we shall have a much larger number of students preparing for the Minor, and in these the strength of the Association will be found; for, having passed the Preliminary, these will be ready to study for the Minor, and being almost unable to obtain assistants' situations, if, at the expiration of their apprenticeship they remain unpassed men, they will probably, by earnest study, endeavour to fit themselves for the Minor ordeal by the time they attain their majority.

Another ground of hope for the future consists in the possessions of the Association, such as a well-stocked library, a working laboratory, a carefully arranged museum, and suitable rooms for the usual meetings. With these advantages, unenjoyed by the members of early sessions, the assistants and apprentices of the future should have an easy task before them to make the Society more flourishing than heretofore. But how is this to be obtained? First, by the committee arranging suitable classes and lectures—to find gentlemen to conduct these should be no very difficult task; secondly, the presidents should be those who will bring as far as possible honour to the chair; thirdly, the secretary should be most exact in all matters of detail, such as keeping the attendance list, the giving notice of all important lectures and meetings, together with placing the objects of the Association very conspicuously before each new assistant and apprentice entering the town; fourthly, each member upon joining the Association, should feel that it is his privilege and duty, either to bring new food for thought to the Society's meetings, or at least to make himself acquainted with all matters brought before the members by more advanced minds. If for a moment we think in what alone real success can consist, viz., the obtaining of as large an amount of knowledge as possible, by as many persons as possible, with the smallest outlay possible of time, energy, and money, we shall see to what a large extent the future of the Society depends upon the regular attendance of even the youngest.

And now, having looked at the prospects of our Association, and having seen much to encourage us, it remains with us either to allow the Society, of which it has been said, "It scarcely has its equal in the Midland Counties," to sink into oblivion, or to degenerate into a more social club, or to raise it into a far higher position than it has ever been its lot yet to enjoy. I leave the matter confidently in your hands, only reminding you that it is by individual effort alone that this can be achieved.

Now, gentlemen, with your permission I will offer a few brief remarks upon one or two matters affecting pharmacy. In the first place the Adulteration Act, although so faulty in itself, and administered more faultily, has been of very great service. Through its influence purer drugs are in better demand; official preparations resemble the Pharmacopœia in something more than name; and, although many incompetent analysts have been appointed, yet little harm, except in a few unjust convictions, have resulted from this. The three points in the Act that in our opinion require to be provided for, are—firstly, an authoritative standard of purity of most drugs and articles of food; secondly, a suitable examination to be passed by all gentlemen aspiring to the office of public analyst; thirdly, some provisions by which the retail trader can obtain compensation from the wholesale houses for any article supplied below the official standard.

In conclusion, I will draw your attention to the general prospect of pharmacy in this country. Doubtless, most of the members present have read the articles in the *Pharmaceutical Journal* upon the state of pharmacy in Germany. It must be with some degree of sadness that our fellow labourers on the Continent view the future of their profession, for the conclusions enunciated in these papers, will, I think, commend themselves to every thoughtful mind. But happily a different look-out greets us in England, for instead of a large body of ignorant chemists, we think the day is fast approaching when a much smaller body of well-educated chemists will perform, not only the dispensing duties of the druggists of to-day, but that large portion of it now consigned to the medical profession. Our only sign of downward tendency consists in the large increase of wholesale chemical manufacturers, which necessarily limits to very plain operations the manipulations of the retail laboratory. This, although upon the one hand to be deplored, is much to be welcomed, for perfection of product is not often easy of attainment with the use of small quantities. With these prospects before us, gentlemen, we have every reason to stimulate us to be earnest, patient students of the great book open before us.

Mr. E. H. Butter, in proposing a vote of thanks to the President for his address, congratulated the members on the election of Mr. Clark as President, and said, that whilst Mr. Clark had mentioned the part he and Mr. H. Cooper had taken in the formation of the Society, he had, with characterestic modesty, omitted to state that he himself had been one of the most active promoters of that movement. Mr. Butter also spoke at some length on the most important points of Mr. Clark's address, and remarked that the members might point with considerable satisfaction to the fact, that the gentleman who had been appointed public analyst for the towns and counties of Leicester, Rutland, and Northampton had occupied the Presidential chair of the Association, and had always been one of its most active supporters. He concluded by expressing his desire to do in the future, as he had done in the past, all that lay in his power for the welfare of the Association.

The vote of thanks was seconded by Mr. Wright, and carried with applause.

A vote of thanks was also proposed by Mr. Bishop, in an appropriate speech, to Messrs. Wright and Cadoux, for the time and trouble they had expended in preparing for the entertainment of the evening. Mr. Clark seconded, Mr. Cadoux responded, and the proceedings came to a close.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Friday, *August 7th.*

(*Continued from page* 200.)

The Analysis of Butter.

The President: After the reading of Mr. Stoddart's paper yesterday, I understand that a wish was expressed on the part of some gentlemen, especially interested in the question as analysts, to hear further details. Mr. Stoddart has this morning been kind enough to repeat his experiments in our presence, and he will now exhibit the results.

Mr. Stoddart: After leaving here last night, it was intimated to me that some of my results could not be correct, and to show you that they were correct, I thought I had better bring you the same experiment this morning. The consequence is, I have analysed part of my breakfast. In this tube is the milk which I poured out of the milk jug. At the bottom is the casein, and here are the salts. It is a very good milk, because it has four lines of fat, which is equal to 6·64 per cent. by weight of fat. Then I took a small pat of butter, which is in this tube, and it appears to be really pure butter. This deposit at the bottom is simply curd, which arises from the butter not being well washed—there is no adulterant. Here, on the other hand, is one which has 25 per cent. of something like lard in it. Here is the butter at the top, and the bottom is the white layer of lard. In this case you see there is no curd. This distinctly proves the value of these tubes, and that you may rely upon them. Mr. Squire has repeated the experiment, and has found it quite correct. I was asked yesterday, by Dr. Redwood, how you could distinguish fat from butter, and I replied that you could do so by ether. The bottle that I have this adulterated butter in was shaken up with ether, and at the bottom of the phial bottle you can distinctly see the difference between the two. The yellow butter is at the top, of course it is coloured with annato, or something of that sort, and the white sediment at the bottom is lard. When I mixed pure lard with ether, and held it in my hand, it was as clear and limpid as water. But when it got cold the lard entirely separated, showing that cold ether will not dissolve lard. So that if you avoid any warmth, of the hand or otherwise, you will find that ether will dissolve butter, but not lard. Of course I do not go so far as to say that an artificial butter could not be mixed up as described by Mr. Wanklyn, which I could not detect. I do not profess to know every fat that is made; I only say that, with the ordinary fats that are used, ether will distinguish between the two.

Professor Redwood: I am much obliged to Mr. Stoddart for having taken the trouble to demonstrate the fact which he has just put before the meeting, and which certainly, to some extent, is satisfactory; but I wish, however, just to put the matter to him in rather a different form from that in which he has explained it—probably somewhat in the form that he has referred to as having been adopted by Mr. Wanklyn. Of course we should all be ready to admit that there may be an adulteration of butter that may be detected by this or by other means; that is, there may be a fat, as I put it last evening, which would differ entirely in composition from the ordinary fat of butter—differ in the proportion of the constituent parts of the stearin, and palmitin, and olein, and which, therefore, would have a different melting-point; and seeing that the stearin and palmitin are not acted upon by solvents in the same way and to the same extent that olein is, it would be quite possible to indicate the presence of a fat of that description; suet, for instance, would be very easily detected. But what I meant to say, and what I still hold, is this, that if the butter, instead of being clumsily adulterated, has been dexterously adulterated, and if the foreign fat which has been introduced, is a fat having a similar composition to the butter fat, that is to say, if the proximate constituents are present in the same proportions as in ordinary butter, then it still remains to be shown how their presence is to be indicated. And I say, as I said yesterday, that if this method will indicate the presence of foreign fats in that way, it certainly will be a great step in advance. I think I understood Mr. Stoddart to say that, in one case, where lard had been treated with ether in the same way, it entirely separated. Now, I should like to ask him if there is absolute evidence of the entire separation of the whole of the lard.

The President: In this tube the lard appears partly in solution and partly not.

Professor Redwood: The question would amount to this: is it not the separation of the crystalline and more solid fats which are less soluble in the ether than the others?

Mr. Allen: I have taken a great interest in this explanation by Mr. Stoddart of Mr. Horsley's ingenious apparatus. When Mr. Horsley first published his pamphlet, he sent me a copy, and I very carefully tried this experiment myself, but I must say I did not succeed. I never could get the butter fat to assume this peculiar form in the tube; it always formed a spheroidal globule, so that I could not read it off. However, it is evident that in some way my manipulation was faulty, since Mr. Stoddart has succeeded very capitally. He told us just now that the milk he had for breakfast had upwards of six per cent. of butter fat in it; but it is a curious thing that when you estimate fat in other ways it does not yield more than three or three and a-half per cent.; therefore, I should like to know why it is we have upwards of six per cent. estimated in this way. It is very evident, I think, that the fat is not pure; it is liquid at ordinary temperatures, and shakes about in the tube in a very different manner to oil, and it is evident to me that it contains something else, I presume a mixture of ether not thoroughly separated. I presume, therefore, that in order to get the exact amount of the fat, we ought to drive off the ether, and dry it. With respect to the application of ether for the distinguishing of other fats in butter, I have used ether myself very frequently, and believe it is a most useful test for the purpose, and this seems a nice way of applying it; but I quite agree with Dr. Redwood that it is merely a question of stearin, which is the principal constituent of suet and lard, being less soluble in cold ether than the olein and butyrin contained in butter. To say that lard is not soluble in cold ether is merely to say that stearin is sparingly soluble in cold ether, and I think if Mr. Stoddart takes a given quantity of lard, and shakes it up in a given quantity of ether, he will find a portion of it will dissolve even in the cold ether. Then comes the question, if you have fats of the same constitution as this, in butter how are you to recognise the existence of foreign fats? You must remember that butter is peculiar in containing butyrin, that is, butyrate of glycyl. That is not found in any other animal fats, and it has been proposed, I think by an assistant of Dr. Hassall, to get an idea of the amount of butter in any mixture on this principle. If we saponify olein and stearin, we obtain a certain amount, I think about 95 per cent., of solid stearic acid. Now, if we take butter, we only get about 85 per cent. by weight in the form of insoluble fatty acids; therefore, there is a clear 10 per cent. difference to work upon. If we have butter we ought not to have more than 85 per cent., but if we have a mixture of foreign fats, it would go from that up to 95 per cent.

Mr. Ekin: I was rather surprised to hear Mr. Allen say that he found any difficulty in working that apparatus, because since Mr. Stoddart brought it under my notice I have tried it several times, and have never had the slightest difficulty. I cannot think that Mr. Horsley's directions have been properly followed, or there would have been no failure. Then as to the discrepancy Mr. Allen finds between his measure of the oil and the weight, I have checked it over and over again by weighing it, and found it quite accurate. Mr. Horsley tells you that a certain measure weighs so much, and that I have checked on several occasions, and found perfectly accurate. He says nothing in his pamphlet about butter, and that application of his apparatus is entirely due to Mr. Stoddart. The fact is indisputable that though we may talk very learnedly about stearin, butyrin, and so on, practically Mr. Stoddart has been doing for months now what I perceive, by reports in the papers, London analysts have not been able to do; he has condemned, and on the strongest grounds, I think, several samples of butter, and the consequence is that Somersetshire, at any rate, gets the benefit of it, for the butter supply is considerably improved there. I must add that I have been exceedingly struck with the extreme readiness with which Mr. Stoddart always imparts any fresh knowledge he obtains, to others. Indeed, he seems to take the greatest pleasure in doing so.

Mr. Allen: I should like to explain to Mr. Ekin, with regard to the proportion of weight and volume, that what I meant was this:—When we hear of upwards of 6 per cent. of butter fat being found in milk, I say that milk does not contain that amount, and therefore it is evident it must not be taken by the volume there. It may be that the volume always bears a certain proportion to its weight, but you cannot actually estimate the per-centage in such a way, because it is quite certain there is not 6 per cent. of fat in milk.

Mr. Ekin: I maintain that the volume of the oil is in direct and constant relation to the weight of pure butter fat.

Mr. Estcourt: I understood Mr. Stoddart to say there was 6 per cent. by weight of fat in that milk. Now I believe that percentage has never yet been found.

The President: May I ask Mr. Ekin whether he carefully dried the fat, and drove off any trace of ether there might be present in it before weighing.

Mr. Ekin: Yes, on several occasions. The fat was dried in a platinum capsule on a water bath, until it ceased to lose weight.

Mr. Allen: What weight does it dry to? It does not dry so as to leave you 6 per cent. of dry fat?

Mr. Ekin: The percentage of fat of course varies in different samples of milk. All I say is, that there is a constant relation between the weight and the measure, and that what Mr. Horsley states is correct.

Mr. Stoddart: I do not know whether Mr. Allen was present yesterday, but if he had been I do not think he would have said what he has. To say that milk has not 6 per cent. by weight of fat, is not correct, for Alderney cows to begin with, for I have cows at home which I milk myself that had 25 per cent. of cream thrown up according to the usual lactometer, and that which I brought up the day before yesterday in one of these tubes, showed 6 per cent. of fat in it. I then put 50 per cent. of water in the next tube to that, and that showed exactly two lines, whilst that with 25 per cent. of water showed exactly three lines. In a fourth tube I skimmed off the cream, and put 50 per cent. of water, and that showed one line. This process, therefore, is very consistent. I have tried it over and over again, thirty or forty times, and I really must say that if Dr. Voelcker, for instance, has any cows that do not agree with ours, he had better send them down to Somersetshire. There is such a tremendous difference of result between the London chemists' and Mr. Ekin's and my own examinations, that we cannot explain it at all. We can only suppose that our cows must be fed on better material, or that they are a different kind of animal. With regard to the fat in butter, I would ask Professor Redwood what fat there is that would resemble butter so closely, because I am not aware of any. I must confess that I had something to do with butter manufacture about ten years ago, and know something about it. In the first place you do not get absolutely pure lard; what is sold for lard being simply pieces of meat boiled in water and the fat skimmed off. To adulterate butter you must have something that pays; it will not do to make an expensive fat for this purpose, and I am not aware of anything that is cheaper except what I came across some months ago, when I found that a glue manufacturer was melting up the bits cut off the skins and selling it to mix with butter. I know, as a truth, that three hundred tins of butter were sent out of England about eight years ago, which only had thirty per cent. of butter in it, and about ten months afterwards an order came back for a repetition of the cargo, with the orders that it was to be exactly the same quality, because it was so much approved of. Now, such a thing as that must have been easily detected. I have had a lot of French butter in my laboratory, which has made quite a mess in the place from the water and salt running out at the bottom. Speaking practically, it would not pay to put less than twenty per cent. of fat into butter, and if you have such a mixture, and shake that up in a phial with cold ether, holding it by the neck so as not to warm it, if it is pure it will dissolve perfectly, but if there is anything foreign in it, it will go to the bottom. The only ground for mistake is this, that butter sold in the country very frequently has a quantity of whey with it, and thus you may have a curd going to the bottom. But that may easily be determined by putting a little on a glass slip and warming it. These experiments prove that two things in our ordinary books are wrong. First, that ether will not remove fat from milk, because here we see that it does so; and on the other hand I am satisfied that lard, or any other fat that I am aware of in the meat way, will not dissolve in cold ether. When I put the lard into some of Mr. Squire's ether just now, it was as clear as the water, because I held it in my hand, but in two or three minutes, when it got cold, it all separated.

Mr. Linford: Dr. Redwood alluded just now to the possibility of adulterating butter scientifically, and I may mention that not long ago I had the opportunity of seeing beef suet treated in such a way that its melting point was reduced to within two degrees of that of butter, and the consistency was almost the same as butter, so that with the addition of a very little butter to it, it was exceedingly difficult to tell that you were not eating good fresh butter. In that instance, pure fresh beef suet was used. Now, the question arises, how the alteration was made in the suet; that I was not able to learn, but it struck me it was attained in this way. We all know that if a piece of fresh meat containing fat is boiled and the fat skimmed off, the fat becomes soft and does not set hard, whereas, if the same fat be boiled in plain water without the lean meat, when the cake of fat is taken off it sets as hard as tallow. Now, I have very little doubt that whatever substance it is in the meat that prevents the fat acquiring the same melting point, was that which was made use of in this article. It is now exported very largely to France and sold as *beurre de cuisine*, and I believe a large proportion of it is re-imported and comes back here as the best Ostend butter. It would be interesting to find out if Mr. Stoddart could distinguish this from the ordinary butter as well as the lard.

Mr. Estcourt: I wish to call attention to the fact that Mr. Horsley gives himself as the quantity of fat in average milk, 3·32 per cent., and I should like to know how Mr. Stoddart arrives at his result of 6 per cent. by weight.

Mr. Stoddart: The average of milk is certainly 3·32. I do not say that this sample I have here is the average, I only say it is the simple fact that it contains 6 per cent.

The Conference then adjourned for luncheon.

On re-assembling at two o'clock, the first paper read was on—

Liquid Extract of Sarsaparilla.

BY H. BARTON.

At the present time sarsaparilla does not appear to sustain the high position once held by it as a remedial agent, and the question arises, were its reputed good qualities a delusion, or are the usual preparations of it defective? Looking into the older compendiums of pharmacy, such as Dr. Jourdan's Pharmacopœia Universalis, it becomes strikingly apparent that considerable boiling was thought an essential, and it is beyond question that well-boiled decoctions were in great favour; but when it became necessary to meet the demand for concentrated preparations, or liquors, it was, and with good reason, supposed that, however well decocting might exhaust the root, the continued application of heat dissipated into the surrounding atmosphere much of its peculiar aroma; also after a time the concentrated decoctions deposited in considerable quantity a something which would, most likely, contain further portions of their active properties. I used to dispense a much-prized old prescription, written by the late Dr. Scott, of Bromley, principally, Pulvis Radicis Sarzæ, the verbal instruction to the patient having been, "Mind where you get this, and do not be persuaded to take any of the concentrated decoctions; I have no faith in them."

We now come to the truly "elegant extracts," the preparations *par excellence* for appearance and good-keeping qualifications, those made by cold or moderately hot infusion and careful evaporation, leaving, so far as appearance is concerned, nothing to be desired; but, looked at in the light of a more than usually interesting reprint, which appeared in the *Pharmaceutical Journal* some thirty one years ago, of a paper read by Mr. T. J. Husband, of the Philadelphia College of Pharmacy, I much fear these "elegant extracts" are at the bottom of the present lukewarm reputation to which, in this country, the drug has descended. Mr. Husband advocated the use of alcohol in the processes for preparations of sarsaparilla, and expressed fear that the permission to make compound syrup by a cold water method would result in the destruction of its valuable character. His experiments and the report of the committee to whom his paper was referred, appear well worthy of re-perusal and consideration at the present time. Bearing them in mind, I have for the last ten years departed somewhat from the *letter* of the official process, and thrown rather more *spirit* into the fluid extract in the following manner:—Each ten pounds of select fibrous root, after being dried and coarsely powdered at a loss of about 8 per cent., has been equally moistened with a gallon of dilute alcohol, containing 25 per cent. of 60 over-proof spirit, and set aside for ten days, then pressed, giving up 65 to 68 ounces of fluid, the pressed root well worked up with five gallons of water at 160°, set aside for about sixteen hours, and again pressed, the watery solution decanted and evaporated to about ten pounds, filtered, and further reduced to make, with the spirituous portion, 80 fluid ounces. Prepared in this way the liquid extract retains more of the taste and smell of sarsaparilla than a liquor made in strict accordance with the letter would do; still to my mind it is not a satisfactory preparation, nor in any respect equal to the following unorthodox sample:—

Take 40 ounces similar root, dried and coarsely powdered, moisten with 40 ounces *proof spirit*, set aside ten days, press from it 20 ounces; macerate the pressed root for sixteen hours with 15 pounds of water at 160°, press, decant the liquid into a water-bath, adding 8 ounces of sugar, and evaporate to produce, with the spirit portion, 40 ounces, each f℥j representing ℥j of the root. Thus prepared, the proof spirit is very much charged with the odour and taste of sarsaparilla, and has to a high degree the frothing characteristic; again the addition of a little sugar to the aqueous solution exerts a marked influence during evaporation, filtering being unnecessary, the finished product depositing scarcely anything. It may be said there is considerable loss of spirit; loss I admit, but waste I do not think; that remaining in the bulky pressed powder, is rapidly diffused in the hot water, and, although dissipated during subsequent evaporation, would leave in the saccharated solution what it had dissolved. One further experiment: 1 lb. transversely cut select root was digested as directed in the Pharmacopœia in two waters at 160°, kept hot during the twelve hours; the second portion pressed away by hydraulic force to exhaust the root so far as this process can do so; the liquid reduced in water bath, at a temperature never exceeding 165°, to make with the spirit fl. ℥viii. The root having been redried and bruised was moistened with 16 oz. proof spirit, set aside four days, when it was again pressed, and from it obtained a fluid, a little of which, added to water and shaken, froths up, developing the odour in a decided degree; or a few drops tasted, leaves upon the palate a persistent rather pungent taste, showing that digestion with seventeen and a-half times its weight of water at 160°, and pressed away by a force not always applied in practice, still leaves the root retaining much that we should suppose ought to have been in the "Extractum sarsæ liquidum."

The President: We have to thank Mr. Barton for an account of the experiments he has carried out, as I have no doubt you will do. The preparation, made by treating the root first with proof spirit, and subsequently with water and sugar, appears to me to be a very capital sample of Liquor sarsæ; it contains more of the active principle than usual, which I think depends upon saponin. I think it is that which causes that frothing and also that turbidity when a sarsaparilla preparation is treated with an acid. I have long been of opinion that the comparative value of sarsaparilla preparations would be indicated by the amount of turbidity caused by acidulating them with hydrochloric acid. There is no doubt that in southern countries the use of sarsaparilla is attended with far more benefit than it is here. In many cases it, and nothing else, is used for the cure of syphilis.

The vote of thanks was passed unanimously.

The next paper read was—

A Note on the Administration of Phosphorus.

BY JOHN WILLIAMS, F.C.S.

A short time since I had occasion to prepare a solution of phosphorus in mixed alcohol and glycerine. The form is given, though not quite accurately, in the *Pharmaceutical Journal*, No. 191, page 684, but practically it may be considered to be a solution of 12 grains of phosphorus in 9 fluid oz. of alcohol, to which 9 fluid oz. of glycerine is afterwards added; it consequently should contain $\frac{1}{75}$th grain of phosphorus to each fluid drachm.

The solution of the phosphorus in alcohol is not easily effected; in the cold, alcohol hardly acts upon the phosphorus. To effect the solution it is necessary that the alcohol should be heated, and kept at a temperature rather under its boiling point until the solution is complete. I find it requires from 12 to 24 hours to dissolve the 12 grains of phosphorus in the 9 oz. of alcohol, and it must be done either in a flask or retort so arranged as to condense and retain the spirit. A flask immersed in a water bath, fitted with a good cork, through which passes a long narrow tube three or four feet long, answers very well, the alcohol condensing in the tube, and dropping back into the flask, and unless the alcohol is made to actually boil, the loss of the spirit is quite trifling.

This process is of course a very tedious and troublesome one, and it struck me it might be possible to materially simplify it by reversing the mode of proceeding, and upon trial it was found that hot glycerine easily dissolves phosphorus, although most of it is deposited on the cooling of the glycerine. Still some is retained in solution, as can be proved by adding it to a solution of chloride of gold, when purple gold is at once precipitated.

To make the solution of phosphorus, therefore, 12 grains of phosphorus were dissolved by shaking for a few minutes in 9 fluid oz. of pure glycerine, heated in a bottle sufficiently large to hold three times the quantity, and then the absolute alcohol, previously heated to an equal temperature, was added, and the whole well shaken for a few minutes. In this way, a perfect solution was effected in as many minutes as it required hours to do it by the other process; but it was found, that although the solution was perfect at first, some phosphorus was always deposited by standing for about 12 hours. This was very puzzling, and led me to examine the two solutions more carefully, as it was evident that 12 grains of pure phosphorus was more than could be held in solution by 18 fluid oz. of mixed glycerine and absolute alcohol.

Upon testing the two liquids diluted with water, it was found that the alcoholic solution of phosphorus was highly acid, while the recently prepared glycerinic solution hardly reddened litmus paper; thus proving, what might have been predicted, that a large proportion of the phosphorus was oxidized during the long digestion in hot alcohol, while that hardly occurred in the glycerine solution.

I have attempted to determine the quantity of real phosphorus (unoxidized) retained in the two solutions, and although my experiments have not proved quite conclusive, they still possess some interest.

If we add a solution of phosphorus to bichloride of mercury, reduction occurs on boiling, and calomel is precipitated. If we suppose phosphorus becomes entirely phosphoric acid, and that the precipitate is entirely calomel, as shown in the following equation—

$$P_2 + 10HgCl_2 + 5\,H_2O = P_2O_5 + 10HCl + 10\,HgCl\ ;$$

then 62 grains of phosphorus should produce 2350 grains of calomel, or 1 grain of phosphorus $= 37{\cdot}9$ of calomel. Of course the amount of oxidation of the phosphorus ought to be shown by the deficiency in the amount of calomel produced, and as each fluid ounce of the solution of phosphorus is calculated to contain $\frac{2}{3}$ grain of that body, we ought to obtain, in round numbers, 25 grains of calomel from that quantity.

A trial was made by dissolving 5 grains of phosphorus in sufficient alcohol as rapidly as possible, and with the least possible exposure to air. It should have yielded 188·6 grains of calomel—it only yielded 131·0 grains, thus nearly one-third of the phosphorus was oxidized.

In another instance, where the solution had been effected in a large flask, and had required application of heat during twenty-four hours, the amount of calomel produced from the solution of $\frac{2}{3}$ grain of phosphorus, instead of being 25 grains, as theory indicated, only gave 4 grains, thus proving that hardly any phosphorus as such remained in the solution.

Testing the glycerinic solution of phosphorus prepared as previously described, and after it had deposited its excess of phosphorus, I obtained 11 grains of calomel from one ounce instead of 25 grains, which it ought to have yielded, had the whole of the phosphorus remained in the liquid. This would show that rather more than half the phosphorus is deposited, and that $\frac{1}{24}$ grain is nearer the quantity which can be held in solution in an unoxidized condition than $\frac{1}{12}$ grain.

However, there are several reasons why the results of these experiments are not conclusive. Not only phosphorus itself, but the lower oxides of phosphorus, equally reduce chloride of mercury, and although I thought I might have been able to obtain some constant by which I could calculate the proportion between the unoxidized and the oxidized phosphorus, I have not succeeded in doing so. We must also remember that the precipitate may consist partly of phosphate of mercury; and I think it likely if the phosphorus has been oxidized to the state of hypophosphorous acid, that some at least of the mercury might form hypophosphite of mercury, and thus remain in solution, and this may account for the very low per-centage of calomel I have sometimes obtained.

Considering the whole matter, however, I think the glycerinic solution of the phosphorus a very good and advantageous form of exhibiting this element; that it contains the phosphorus in an unoxidized condition is easily proved by adding some to water, when the phosphorus is separated in a milky form. The taste also is very marked, for, although sweetened somewhat by the glycerine, the strong garlic-like flavour of the phosphorus is very pronounced.

I think if such a solution as I have described should be employed in medicine, caution should be used as to the dose to be administered, as I am strongly of opinion that many of the preparations in use, and supposed to contain a certain per-centage of real phosphorus, would, if carefully examined, prove to contain it in a condition more or less oxidized, and thus medical men may have been deceived as to the real maximum dose proper to be administered.

A vote of thanks was passed to Mr. Williams.

The President: The use of phosphorus is now becoming very general, I suppose from our overtaxed brains requiring a little stimulus of that kind. I hope, therefore, that Mr. Williams's experiments will tend to make its exhibition more controllable than it has hitherto been.

Mr. Umney: I look upon Mr. Williams's experiments as very valuable. I should like to ask him whether he subjected the alcohol to any special treatment before he made these experiments in order to determine whether it contained any acetic acid, aldehyde, or any of the other bodies which are frequently present in alcohol.

Mr. Williams: I used pure absolute alcohol, not ordinary spirit.

Mr. Martindale: The disagreeable taste of phosphorus when administered in a liquid form, is objectionable, but the glycerine solution seems to be a very elegant method of giving it. I did not quite catch the strength which Mr. Williams would recommend.

Mr. Williams: I believe the right strength which can be made practically is from $\frac{1}{30}$ to $\frac{1}{24}$th grain in each drachm of absolute alcohol and glycerine in equal parts.

The President: What is the medicinal dose?

Mr. Williams: From $\frac{1}{30}$th grain to $\frac{1}{10}$th grain, but I should be inclined to take a somewhat smaller dose.

The President: That would be about one drachm of the glycerine solution to a dose.

The Utilization of Iodoform Residues.

BY EDWARD SMITH, F.C.S.

Iodoform, or tri-iodomethane (CHI_3,) may be obtained by the action of caustic or carbonated alkalies on ethyl alcohol, acetone, aldehyde, and several other bodies. It is, however, I believe, very generally prepared according to the well-known formula of Wittstein, by heating in a water-bath a mixture of iodine, ethyl alcohol, potassium carbonate, and water, until the reaction is completed, and the liquid colourless. Wittstein does not recommend any particular temperature, other than that of a water-bath, but says, "The receiver must during the operation be well cooled."

I have found that if the temperature is kept down to 68°—70° C., there is no necessity to attach a receiver, since but very few cubic centimetres of condensible bodies pass over. I use a glass flask fitted with a thoroughly sound cork, through which passes a long (———) tube protruding half an inch or so into the flask, and exteriorly bent at an obtuse angle, so that any fluid condensed in the tube runs back into the flask.

The yield of iodoform is from 16 to 17 per cent. of the weight of iodine employed. The reaction is somewhat complicated, but may be written thus :—

$$7\,I_2 + 6\,K_2CO_3 + C_2H_6O + n\,H_2O =$$
$$CHI_3 + KCHO_2 + 6\,CO_2 + 10\,KI + KIO_3 + 2\,H_2O + n\,H_2O.$$

This does not express the exact reaction, for then 7 molecules of iodine should yield one molecule of iodoform ; or about 21 per cent. of iodine employed should be utilized in building up iodoform, but this per-centage is never reached in practice. Five-sixths ($\frac{5}{6}$) of the iodine is found in the filtrate from iodoform as iodide and iodate of potassium together with some little potassium formate, produced during the operation, and the excess of potassium carbonate. Wittstein secures the iodine in this residue by evaporating to dryness, and heating to redness with "powdered wood charcoal," digesting with alcohol, filtering and evaporating to crystallization. This answers well when large quantities are operated upon, but, upon a small scale, such as most pharmacists would undertake, the iodide does not come out well.

Rother (*Pharm. J.* [3], vol. iv., p. 594,) has propounded a method of overcoming some of these difficulties, by freeing the iodine in the residue by an acid in conjunction with acid potassium chromate; more iodine and potassium carbonate are then added, and the mixture heated. In this way successive crops of iodoform are obtained, the last filtrate, however, still holding iodine.

The process I have devised, and successfully employed many times, to secure the whole of the iodine in a useful form from the filtrate, is as follows :—

The filtrate from the iodoform consists essentially of—

$$n\mathrm{KI} + n\mathrm{KIO_3} + n\mathrm{K_2CO_3} + n\mathrm{KCHO_2} + n\mathrm{H_2O}.$$

If now a stream of sulphuretted hydrogen be passed through the solution the iodate is reduced to iodide, and sulphur is precipitated, according to the equation :—

$$KIO_3 + 3\,H_2S = KI + 3\,H_2O + 3\,S.$$

The solution is now gently warmed to expel excess o sulphuretted hydrogen filtered to remove sulphur ; and whilst warm, cautiously neutralized with nitric acid, to drive off the carbon dioxide from the potassium carbonate. We now have in solution simply :—

$$n\mathrm{KI} + n\mathrm{KCHO_2} + n\mathrm{KNO_3} + n\mathrm{H_2O}.$$

To this is now added lead nitrate until all the iodine i precipitated :—

$$2\,KI + KNO_3 + KCHO_2 + Pb\,2\,NO_3 =$$
$$3\,KNO_3 + KCHO_2 + PbI_2.$$
s

If by chance the PbI_2 should carry down a trace of lead formate, very slight washing removes it, inasmuch as the formate is soluble to the extent of about 1 part in 40 of water, whilst PbI_2 is practically insoluble in cold water.

The following, taken from my laboratory note-book, will show the results of actual working :—

96 grams iodine were heated, in a water-bath, at 68° C. with alcohol, potassium carbonate, and water, until all action ceased ; solution filtered, the iodoform washed and dried ; weight = 15 grams. Now, 15 grams iodoform contain 14·5 grams iodine ; therefore, leaving 81·5 grams iodine in filtrate. H_2S passed through solution to excess, filtered, neutralized with nitric acid and finally lead nitrate added, the resulting precipitate washed and dried ; weight = 146·0 grams. Theoretically, the 81·5 gr. iodine should yield 148·0 gr. very nearly, so that the difference, viz. 2·0 gr. lead iodide, which contain 1·1 grams iodine, represents the loss of iodine. Working on a small scale, the loss of iodine, therefore, barely exceeds 1 per cent, and, doubtless, working with larger quantities, a proportionately less percentage of loss would be realized.

The product obtained (PbI_2) is one of common use in pharmacy.

Rother, in the paper above referred to, states that "the most satisfactory results are obtained by the use of wood spirit. In this case the yield of iodoform, at each operation, exceeds one-third the weight of iodine used." "An exceedingly irritating gas (to the eyes) is simultaneously evolved." I am unable to corroborate this statement. I have observed that different samples of methylic alcohol yield very varying amounts of iodoform. I doubt very much if *pure* methylic alcohol yields any iodoform whatever. The product obtained by operating upon commercial methylic alcohol is, in all probability, derived from acetone or some analogous body, invariably present in the wood spirit. The gas evolved may be methylic aldehyde, which, of course, would very speedily absorb oxygen to form formic acid. At the present moment, however, I am unable to speak with certainty. I propose, therefore, at some fitting opportunity, to operate upon *pure* methylic alcohol obtained from methyl oxalate, and thus set at rest the question whether or not methylic alcohol yields iodoform.

A vote of thanks having been passed to Mr. Smith.

The PRESIDENT said : There are not many pharmacists who, like Mr. Smith, will take the trouble to make iodoform, a thing not very frequently used, or required in large quantities ; but I know that he makes a point of making everything that can be made with any advantage, and I wish his example were more frequently followed.

Mr. STANFORD : May I ask Dr. Attfield to read again the portion which refers to the precipitation of iodine by charcoal.

Professor ATTFIELD, having re-read a passage from the paper, said : That is simply to take away the oxygen from the iodate. I have never found any difficulty in obtaining iodine itself from such a residue, not only by merely adding a little nitric acid, as recommended by Mr. Smith, and then iodide of lead, but by continuing the addition of nitric acid; hydriodic acid is set free, and then on gently warming it the nitric acid attacks the hydriodic acid, and you get free iodine which you can collect and wash. With regard to methylic alcohol, there is one very good method, I think, of obtaining it, that is, by treating common wood spirit with chloride of calcium, evaporating to dryness, and pretty strongly heating the residue—not enough to char the compound, but to get rid of any volatile matters ; then add water, which decomposes the crystalline compound of chloride of calcium with methylic alcohol which is formed, and distillation gives you methylic alcohol, which one or two fractional rectifications will render nearly pure.

Mr. WILLIAMS : Some of Mr. Smith's results do not quite accord with my experience, because, in making iodoform, there is, no doubt, a large quantity of volatile compounds of iodine—iodide of ethyl, for instance—always produced ; and a considerable loss of iodine, much larger than Mr. Smith speaks of, occurs from the volatilization of this organic compound. I do not think it would be possible to carry on the process with a loss of only 1 per cent. of the iodine used, for I have never succeeded in doing it without a loss of nearly 10 to 15 per cent.

Professor ATTFIELD : Mr. Smith would probably condense the volatile compounds in his long tubes, though something would depend on their length.

Mr. STANFORD : When Professor Attfield first read the paper, I thought allusion was made to a method of precipitating iodine by charcoal, but I find that is not the case. I asked the question because the affinity of charcoal for iodine is so remarkable. It has been one of the greatest difficulties I have met with, in making seaweed into charcoal instead of kelp; we can produce about three times the amount of iodine obtained in the ordinary way, but there is an extreme difficulty in washing the charcoal; in fact, washing the iodine from the charcoal on a large scale is really impossible. We are obliged always to use caustic soda for the purpose. As an iodine manufacturer, I must say I feel bound to discourage as far as possible any method of saving iodine, for what we want is some new method of securing a better outlet for it. I should like to add that none of these processes which have been constantly brought forward for the manufacture of iodine have ever been successful in the manufacturer's hands. The old process of distillation with manganese and sulphuric acid is still followed just as it was twenty years ago, though the form of the apparatus is a little altered. The reason of this is that none of the new processes will produce iodine in a dry commercial state; whilst the old method of employing a large quantity of oil of vitriol enables the iodine to be got at once in a perfectly dry form, and fit for the market.

Syrups containing Phosphoric Acid.

BY SILAS DANIEL.

The difficulty of preparing chemical food according to the formula published in Parrish's "Practical Pharmacy" is well known. The phosphate of lime is only partly soluble; the strict operator is puzzled to know how much the syrup should measure when completed. He probably thinks that he has solved the difficulty when he finds in the description of the syrup that each teaspoonful contains "about" 1 gr. phosphate of iron, and $2\frac{1}{2}$ grs. phosphate of lime. Beginning with the lime phosphate, he finds that to agree with the description, the syrup should measure 36 fluid ounces. Attempting to check these figures, he calculates the quantity of ferrous phosphate produced —supposing all the iron to be utilized, which, as will be shown, is not the case—he finds that if he makes 36 fl. ozs. of syrup, each fl. drachm will only contain ·894 of a grain of phosphate of iron. As is now shown in recent works on elementary chemistry, when phosphate of soda and sulphate of iron are mixed together, sulphuric acid is liberated, $2\,Na_2HPO_4 + 12\,H_2O + 3FeSO_4,7H_2O = Fe_3P_2O_8 + 2\,Na_2SO_4 + H_2SO_4$, which would dissolve a portion of the newly formed phosphate.

Again, can a syrup be made to contain 40 ozs. (apothecaries') of sugar, besides several kinds of phosphates and acids, and be limited to 36 fl. ozs., and have all its constituents in solution? It is palpably impossible. Neither is the difficulty removed by using phosphate of lime, made by double decomposition from chloride of calcium and phosphate of soda, and a smaller quantity of sugar. The phosphate readily dissolves in the acid, forming a strong solution; but immediately sugar or syrup is added, in spite of a liberal use of hydrochloric acid, a gelatinous precipitate is the result.

An elegant syrup, of definite composition, and which keeps fairly well, may be made by using tribasic acid. The method I adopt is as follows:—

Syr. Ferri Phosph. Co.

Sulphate of Iron	671	grains.
Phosphate of Soda	2503	"
Acetate of Soda	222	"
Chloride of Calcium	585	"
Carbonate of Soda	40	"
Carbonate of Potash	60	"
Cochineal	120	"
Phosphoric Acid, syrupy, sp. gr. 1·5	30	fl. drachms.
Sugar	24	ounces.
Orange Flower Water	1	"

Dissolve the sulphate of iron in 3 ozs. and the acetate and 600 grains of the phosphate soda in 8 ozs. warm distilled water. When quite cold, mix the two solutions, and, after careful stirring, wash the precipitate, by means of decantation, with distilled water, and collect on a filter. Dissolve the chloride of calcium in 1 oz., and the remainder of the phosphate in 17 ozs. warm distilled water. When cold mix the two solutions, wash by decantation, and collect on a calico filter. After draining submit the precipitate to strong pressure. Dissolve the two precipitates in the acid. To the solution add the carbonates, which should first be rubbed down in a mortar with a few drops of distilled water.

The cochineal having been reduced to a very fine powder, is mixed with the sugar and 13 ozs. of distilled water, and the whole raised to the boiling point. Strain through flannel, and when quite cold add the orange flower water, the solution of phosphates, and distilled water, if necessary, to make 36 fluid ounces.

By boiling the sugar and cochineal a bright syrup of rich colour is produced. It contains 1 gr. phosphate of iron, $2\frac{1}{2}$ grs. phosphate of lime, and fractions of grains of phosphates of soda and potash and acid equal to about 35 min. acid. phos. dil. B.P. in each fluid drachm. Sp. gr. 1·308.

The difficulty of keeping unchanged syrup of phosphate iron, B.P., for any length of time has been recognized by all. Several chemists have at various times made experiments with a view of preventing this change, but to the present time no satisfactory result has been ascertained. Recognizing this, Mr. Carteighe, some time ago,* in order that it might be made with greater facility, at shorter intervals, published formulæ for shorter processes for this and other allied syrups, in which phosphoric acid, sp. gr. 1·5, is used, instead of the ordinary dilute acid of the Pharmacopœia. As the phosphates to be used in these processes were only to be a few days old, and would practically have to be made purposely, it is very questionable whether the processes would be shorter than the B.P. method. More recently, two writers have proposed a liquor ferri phosphatis to be mixed with the syrup when required. It has been stated that the solution keeps for an indefinite length of time. It becomes interesting to know whether it is as stable as has been claimed for it. In the early part of last December I prepared solutions of phosphates of iron, iron and manganese, iron and lime, and manganese. Bottles were filled with the solutions and placed in a dark cupboard. In June last, six months after having been made, no change was perceptible. Being out of the syrup I had to open the bottle and use some of the liq. ferri phosph. Since that time a slight but distinct deposit has taken place, whilst the colour has remained unchanged. The latter fact seems to confirm the conclusions of the President of the Conference, that the dark colour is due to the production of caramel by the action of the phosphoric acid and the iron salt upon the sugar.† The brown tinge noticeable in all the solutions containing ferrous phosphate is the same as when first prepared, and is probably due to the partial oxidation of the salt during washing. It is not discernible when mixed with syrup. Considering the length of time the solution has been made, the amount of deposit is very small, and consequently the solution is an excellent method of preserving the salt.

In the following formulæ the proportions of phosphoric acid and phosphates correspond to those given by Mr. Carteighe:—

Liq. Ferri Phosphatis.

Sulphate of Iron	224	grains.
Phosphate of Soda	200	"
Acetate of Soda	74	"
Phosphoric Acid, sp. gr. 1·5.	7	fluid drachms.
Distilled Water	q. s.	

* *Pharmaceutical Journal*, 3rd series, i., 761.
† *Ibid.*, 2nd series, vol. xi., p. 138.

Dissolve the sulphate of iron in 1 oz., and the phosphate and acetate of soda in 2½ ozs. of warm distilled water. When quite cold, mix and well stir the two solutions, allow to remain for a few minutes and then wash the precipitate, by means of decantation, with distilled water. Collect the precipitate on a filter and allow to drain. Lastly, add it to the phosphoric acid and make up, with distilled water, to 2 fluid ounces. One fl. drachm is equivalent to 6 fl. drachms of syrup.

The tediousness of washing the precipitate as ordered in the B. P. is well known. I have not been able to find, but I have some recollection of a paper by Mr. Groves, suggesting, in order to obviate the difficulty, that after mixing the two solutions, the whole should be boiled for a few minutes, using one-fifth more of each ingredient to make up for the phosphate of iron dissolved in the process. That method appears to me unreliable and unnecessary. Would the quantity of phosphate dissolved be always the same? In the process I have given, the salts are dissolved in just sufficient water to yield nearly saturated solutions at a temperature of 60° F. Warm water is given merely to facilitate the dissolving. In this way the phosphate sinks rapidly, and is easily washed by decantation.

Liq. Ferri et Mang. Phosph.

Ferri Sulph.	168 grains.
Manganesii Sulph.	113 ,,
Sodæ Phos.	247 ,,
,, Acet.	93 ,,
Aquæ Destillatæ	q. s.
Acid. Phos. Glacial.	ʒvi.

Dissolve 150 grains phosphate and 56 grains acetate of soda in 2 ozs., and the sulphate iron in 6 drachms of warm distilled water, and allow to cool. Wash and collect the precipitate as directed in the last. Dissolve the sulphate of manganese in 6 drachms, and the remainder of the phosphate and acetate of soda in 10 drachms of warm distilled water. Mix the two solutions. Wash and collect the precipitate as the preceding ones. Add the glacial acid to the two moist precipitates, and when dissolved filter and add distilled water to 2 fluid ounces; 1 fluid drachm is equivalent to 6 fluid drachms of syrup. The syrup when made will contain ⅔ grain phosphate of iron and ⅓ grain phosphate of manganese in each fl. drachm.

Glacial acid has been used in this preparation, as directed in the *Pharmaceutical Journal*, vol. i., 3rd series, p. 288. It has kept admirably.

Liq. Ferri et Calcis Phosph.

Sulphate of Iron	224 grains.
Phosphate of Soda	200 ,,
Acetate of Soda	74 ,,
Phosphate of Soda	508 ,,
Chloride of Calcium	156 ,,
Phosphoric Acid, sp. gr. 1·5	8 fl. drachms.

The ferrous phosphate having been prepared as before directed, dissolve the remaining phosphate of soda in 5 ozs., and the chloride of calcium in 3 drachms, of warm distilled water. When cold, mix the two solutions, stir and wash. Collect the precipitate on a calico filter, after draining, press it firmly until the weight of the moist phosphate is reduced to 6 drachms. Dissolve the two precipitates in the acid and add distilled water, if necessary, to make 2 fluid ounces. One fluid drachm is equivalent to 6 fl. drachms of syrup, which when made, will contain 1 grain of phosphate of iron and 2 grains of phosphate lime in each fluid drachm.

Liq. Ferri et Strychniæ Phosph.

Sulphate of Iron	448 grains.
Phosphate of Soda	400 ,,
Acetate of Soda	148 ,,
Phosphoric Acid, sp. gr. 1·5	10 fl. drachms.
Strychnia in crystals	3 grains.
Distilled Water	q. s.

Dissolve the sulphate of iron in 2 oz., and the acetate and phosphate in 5 oz., warm distilled water. Wash and collect on a calico filter. After draining, press out some of the remaining water. Dissolve the precipitate and the strichnia in the acid, and add distilled water, if necessary, 2 fl. ounces. One fluid drachm diluted to six drachms with simple syrup will contain in each fluid drachm 2 grains phosphate of iron and $\frac{1}{32}$ of a grain of strychnia.

Liq. Ferri et Quinæ Phosph.

Sulphate of Iron	448 grains.
Phosphate of Soda	400 ,,
Acetate of Soda	148 ,,
Phosphate of Quinine	96 ,,
Distilled Water	q. s.
Phosphoric Acid, sp. gr. 1·5	9 fl. drachms.

Prepare the ferrous phosphate in the same manner as directed for liq. ferri et strychnia phosph., and dissolve it in the acid, and make up with water to 2 fl. ounces. The phosphate of quinine is best added when required.

Syr. Ferri et Quinæ et Strychniæ Phosph.

As has been pointed out, this preparation neither in solution nor in syrup will keep without becoming discoloured. It may be made by adding 6 gr. phosphate of quinine to each fl. drachm of the liquor, or 1 gr. to each fl. drachm of the Syr. Ferri et Strychniæ Phosph.

Liq. Zinci Phosph.

Most chemists keep phosphate of zinc, and, as its solubility is not impaired by keeping, it is best made direct in the manner directed by Mr. Carteighe.

Liq. Manganesii Phosph.

Sulphate of Manganese	226 grains.
Phosphate of Soda	194 ,,
Acetate of Soda	74 ,,
Phosphoric Acid (1·5)	7 fl. drachms.
Distilled Water	q. s.

Dissolve the sulphate of manganese in 1 oz., and the phosphate and acetate of soda in 2½ oz., of warm distilled water. Mix the two solutions. Wash by decantation. Collect on a fine calico filter, and, after draining, press out a portion of the remaining water. Dissolve the precipitate in the acid, and add distilled water, if necessary, to 2 fl. ounces.

One part made up to six with simple syrup will contain in each fl. drachm 1 grain of phosphate of manganese.

The PRESIDENT: Mr. Daniel's formulæ seem to be well thought out and well worked out, and perhaps will be useful to many of us. These syrups are often ordered, and what we want is a rapid mode of making them. The great obstacle to rapidity is the difficulty of washing the precipitate, and I prefer mixing the solutions hot and boiling them. I find that, if instead of using acetate of soda I use carbonate, I get a better result. I mix the phosphate of soda and sulphate of iron, and boil them rapidly; I get of course a precipitate, and a certain amount of phosphate dissolved. Then I put in carbonate of soda as long as effervescence ensues, and I get thrown down a granular precipitate, which is very easily washed. In this way I have been enabled to make syrup of phosphate of iron in about an hour. Omitting acetate of soda does not entirely prevent colouration, though it does so to some extent. I know some have said that the colouration of the syrup of phosphate of iron is due to the formation of peracetate of iron, but that is not so, because syrup made without acetate also colours, though it takes a longer time. I have now to ask you to pass a vote of thanks to Mr. Daniel.

The vote of thanks was passed unanimously.

Mr. EKIN: I have found that the acid solution of the precipitated phosphates will keep for years without the sugar, and the way I manage is to keep a quantity of that, and make the syrup in small quantities as it is wanted.

Mr. Umney: I can quite corroborate what Mr. Ekin has said, for I have for years made a solution of phosphate of iron which I have found to keep very well. There can be no question that the use of dilute phosphoric acid in pharmacy for the manufacture of these syrups will eventually be abandoned, and that the precipitated ferrous phosphate will be dissolved in a concentrated phosphoric acid (1·500 specific gravity containing about 49 per cent. of anhydrous acid, answers excellently). Such a solution will keep perfectly well, and may be added to the simple syrup when required. I have made a solution eight times the strength of the Pharmacopœia, which can be diluted when required by the addition of simple syrup, and in this way one can get a preparation equal, if not superior, to that of the Pharmacopœia.

Mr. Smith: I should like to ask these gentlemen if they do not find a small deposit at the bottom of the bottles of the acid solution. I have made the solution with strong phosphoric acid, and have sometimes found there has been a deposit.

Mr. Ekin: I did not use the strong phosphoric acid, but the dilute acid of the Pharmacopœia, and proceeded precisely the same as the Pharmacopœia orders. The solution thus made keeps, to my knowledge, for three or four years without the slightest change.

Mr. Giles: I should like to ask a question about the precipitation, which the writer seems to think the most tedious part of the process. The phosphate of iron, when first thrown out of solution, appears to subside very tardily, but after it has subsided, and you have decanted one lot, and added water, it precipitates very rapidly, so that you can speedily throw it on a calico filter and squeeze it dry. Finding the first subsidence is so tedious, it occurred to me, that perhaps if more water were used in the first place it would subside more quickly.

The President: Perhaps the hydrated phosphate breaks up and loses its water of hydration.

Professor Attfield then read the following paper by Mr. Heathfield:—

Notes on Extracts of Aconite, Belladonna, Hemlock, Henbane, and Colchicum.

BY W. E. HEATHFIELD, F.R.S.E., F.C.S.

The consideration of this question requires that a distinction should be made between the first four of this group and the last, for whereas in the former the fresh expressed juice contains the starch, albumen, and chlorophyll in a condition of assimilation, in the latter the starch separates at once from the cold liquor, and can be washed so as to leave it tasteless. Thus it is presumable that, in preparing the extract of colchicum, we may be allowed to separate the fœcal part in its natural state, before we deal with the clear expressed juice. Those excellent preparations introduced by Professor Bentley, under the name of expressed juices, and of which the late Dr. Pereira had so high an opinion, save that the large quantity of liquid along with them made them less facile in administration, are good examples of the value of processes undisturbed by heat, where heat, as in the case of these extracts, produces a decomposition. As we do not know, from a hygienic point of view, the exact part that the chlorophyllic and albumenoid substances act in the economy of the medicine, so should we be careful in dealing with separations necessarily accompanying the somewhat rude operations of inspissation. Dr. Pereira was of opinion that the albumen of conium juice, when coagulated, retains a portion of the active principle, mechanically or chemically combined. And the balance of affinities is so much upset by the action of heat that if one element is to be rejected it is difficult to tell where to cease. The chlorophyll separated, the albumen removed, the large proportion of chlorides freed, as it were, from their shackles, and no longer able to do their duty as solvents, the nature of the medicine has undergone so great a change that it is scarcely recognizable. If we are dependent in extract of aconite on aconitia; in that of belladonna on atropia; in hemlock on conia; and in henbane on hyosciamia, we are leaning on a broken reed; and in the able paper of your President on "The Assay of the Alkaloids in Medicinal Extracts," he has pointed out the unreliability of certain processes in reference to it, and I am not aware that any success has resulted from efforts to procure these alkaloids from pharmaceutical extracts. From four ounces of extract of conium, representing about five pounds of the fresh herb, prepared by one of the most respectable makers in London, Dr. Pereira was unable to obtain any sensible quantity of conia, and both Geiger and Dr. Christison have offered their opinion that this extract contains very little conia. Thus we may reason that there may be a medicinal quality so looped up in, and intermingled with, the juice of the plant, that in rejecting what seems superfluous, we may be losing a valuable ingredient. That the well-known Liq. Cinchonæ Cordifoliæ, as prepared by the late Mr. Battley (and which has been imitated at so humble a distance in the Extractum Cinchonæ Flavæ Liquidum of the Pharmacopœia), wherein most of the constituents of the bark were retained, could be taken by a patient with benefit when quinine produced headache, would indicate, as the sagacious introducer of this preparation suggested, that the natural condition, or as near to it as we can sail, is the proper one. And he held a similar opinion with regard to the narcotic juices. In an experiment with 84 lbs. of carefully plucked hemlock leaves, yielding about six gallons of juice, which was subjected to a temperature of little more than 100°, the collected chlorophyll amounted, when dried, to 5 oz. 1 dr. 36 grs. This was subjected to the action of spirits of wine, 56 over-proof, which yielded, on evaporation, 1 oz. 4 drs. 30 grs., having a highly resinoid character, of a beautiful green colour, and smelling very powerfully of the fresh herb. The six gallons of juice were then distilled; the first gallon was powerful of hemlock, and had a little oily substance on the surface. The remainder of the distilled liquid had but little flavour, and the final extract, being $1\frac{3}{4}$ lbs., had little smell or taste of conium. The heat it had been subjected to during the distillation had much injured the extract.

The observations I have now made in allusion to hemlock, are much in accordance with those referable to other narcotics in the green state; and when we consider how small a quantity of their alkaloids seems to exist in the completed extracts, we are, perhaps, entitled to look further for their efficacy. That the aconitia of aconite resides in the root, and the conia of hemlock chiefly in the fruit, has been pointed out by distinguished explorers in this field. From 6 lbs. of fresh, and 9 oz. of dried fruit of hemlock, about 1 oz. of conia was obtained by Geiger, whereas from 100 lbs. of the fresh herb, corresponding to $3\frac{1}{2}$ or 4 lbs. of extract, he got but one drachm. Nor could he get traces in the dried leaves, though from 9 oz. of the fruit which had been preserved not very carefully for about sixteen years, he procured 1 drachm. Dr. Christison produced from 40 lbs. of ripe but green seeds, $2\frac{1}{2}$ oz. of hydrated conia. Mr. Stoddart has pointed out the per-centage of hyoscyamia in the seeds as 3 per cent., but in that of the dried leaves but ·73 per cent. When we take into account the very small proportion of these alkaloids in the parts officinal which are ordered for extract, and further recognize the waste or decomposition they undergo when under the influence of the process, we should hesitate to select the chlorophyll and albumen or starch as victims, until we have established a more accurate discernment of their use and value.

In allusion to colchicum root, I may state that 42 lbs. of the fresh root having been expressed, there was a yield from the cold juice of $2\frac{1}{2}$ lbs. of well-edulcorated starch, the remaining supernatant liquor producing, on evaporation, about $1\frac{1}{2}$ lbs. of extract.

The President: You have heard Mr. Heathfield's paper, and I have no doubt you will accord him a vote of thanks. In one part of his paper he mentions the suggestion of Dr. Pereira, whether the active principle of conium might not be diminished or removed by coagulation, the alkaloid separating in combination with albumen. Now quite recently a French chemist has been examining that very question, and he proves that there is a definite series of combinations between albumen and the alkaloids. He has described his process, and given his formulæ, and there is no doubt about it, I think, that if we make a green infusion, boil and filter it, the coagulum will contain a notable quantity of alkaloid.

A vote of thanks to the author was passed unanimously.

Mr. Schacht: I feel that I owe an apology to the members of the Conference, inasmuch as, by some mistake of my own, my name has been published in the earlier editions of the programme as the contributor of a paper. The mistake arose from the fact that when the President asked me if I should be able to produce anything for this meeting, I told him I was working on a matter which might produce some results worthy of being brought before the Conference, on the subject of the succus and extract of conium. I may now say in what direction I have been working, rather than give the results, which at present are rather imperfect. The idea was suggested to me at the last year's Conference, when Mr. Ekin gave us some experiments on the hydration of extracts, and it occurred to me that that kind of investigation would have been a little more valuable, if he had been able to answer a question which I put, whether he thought anything but water had passed off during the inspissation. He replied that he had not investigated the matter, and I thought I would attempt to do so. In taking the special subject of conium, I thought the succus would be more satisfactory to work upon than the extract, because one finds opinions go generally in the direction of estimating the succus as being the more valuable medicinal material, and I thought it would be interesting to ascertain, if possible, whether, in the process of the reduction of the juice of the plant to the condition of the extract, a very large proportion of the nitrogenous matters were parted with that originally existed in the succus. I spoke of the matter to Mr. Siebold, and I do not think it is quite fair that I should assume the idea as original, for I almost think that in conversation he suggested to me the desirability of adopting the process of estimating it by the plan lately adopted for estimating nitrogenous matters in potable water, using those fine measurements which we are able to employ by the process of Neslerizing. Conium does not come to maturity until somewhat late in the season, and consequently my time has been rather short, and my results have as yet been imperfect. I have tried to satisfy myself of the exact quantity of nitrogenous matter of all sorts, volatile and non-volatile, which existed in a certain specimen of succus, and then I thought, by bringing the same sample into the condition of an extract, one could estimate the proportion of nitrogen then present by a similar process, and satisfy oneself if any large amount had been driven off. I have got through one-half of my task, and have satisfied myself pretty well of the per-centage of nitrogen which the succus contains. I have begun the other part of the work, and have gone so far that I feel quite sure it is considerably less, though I cannot yet venture to say the proportion which the extract bears to the succus, and I am not quite sure that the conclusions one would draw from such comparison would be very valuable. The difficulty is increased by the fact, given on the authority of Mr. Wanklyn, that all nitrogenous alkaloids do not equally yield their nitrogen to this process. I dare say, gentlemen, you are aware of the curious page in his book, in which he gives us two lists with the statement that a certain portion of the alkaloids yield all their nitrogen to this process, but that those in the other list yield only half. That is a very remarkable statement, and one which would not be accepted but on the very highest authority; possibly some gentleman here may be able to confirm it, and if it be so, one would have to ascertain, in the first place, whether the active principles of conium are to be included in the one list or in the other, in order to estimate with anything like accuracy the possibility of the difference in nitrogen being explainable by the passing off of the active principle of conium, conia. I hope at some future time to be able to indicate the results of my experience, in the meantime I can say that, as far as I can make out, the average quantity of ammonia obtained from the Succus conii is ·1776 per cent., corresponding to ·1460 per cent. of nitrogen.

Mr. Ekin: When I suggested last year that Mr. Wanklyn's mode of limited oxidation might be applied to the estimation of the alkaloids in vegetable extracts, I said I meant to work further on the subject. I cannot say that I have yet done so, though I have thought a great deal about it, and furnished myself with all the information I could obtain. I find, however, that the whole subject is in such a fog, that so little is known of the proteid constituents of plant juices, that I am not very sanguine that anything can be done in this direction. Even if it were possible to separate and remove all the vegetable albumen present in the plant juices or extract, there might, and probably would, still remain other vegetable proteids, and which would also yield ammonia. It would be necessary to get rid of these before one could say with certainty that the amount of ammonia yielded by a vegetable extract was due to any alkaloid it might contain. It seems impossible to do this. Also in the case of conium it would be necessary, in the first place, to know the proportion of its nitrogen which conia yields as ammonia when treated with an alkaline solution of potassium permanganate, and one great difficulty would be to get the pure alkaloid, to start with, to ascertain this. I am not sure whether the pure alkaloid can be obtained at all. Therefore, I almost despair of any result being arrived at in our present state of knowledge.

Mr. Schacht: My object would be to endeavour to ascertain whether there was any difference in the yield of the fresh juice and in the extract; if so, you would then be pretty clear that you had parted in the process with certain volatile organic matters.

Mr. Ekin: That is just the point. I do not see how you can be clear that you are parting with the volatile constituents. I think the only way, as you suggested to me some time ago, Mr. President, would be to try and find some precipitant of the alkaloids.

The President: As I understand Mr. Schacht, he takes two ounces of the juice of the plant, evaporates one to an extract, allows the other to remain in its natural state, and compares the two by Nesler's process.

Mr. Stoddart: I must say I think Mr. Schacht's idea is rather a good one. We know the peculiar mouse-like smell of conium, which the extract does not possess. I think it is not to be disputed, therefore, that ammonia is given off in some way or other, and this seems to me to be a very good way of answering the question, whether ammonia is given off in making the extract.

Mr. Schacht: I look upon it in this way that the Succus conii as freshly expressed would, of course, contain a certain mass of nitrogenous material. A portion of that would, of course, be albuminous, which would probably be non-volatile, and a portion of it probably would be conia. I suppose there is such a thing, and probably there might be other active materials, which would be volatile possibly, or possibly not. I should estimate the whole of the nitrogen by a per-centage process. If, after evaporating a portion of the juice to the consistence of an extract, I found that it yielded a certain lessened amount of nitrogen, I should infer that a portion of the nitrogen did really exist as a volatile organic base, and that it had passed off in the process of reduction to an extract. I quite admit that it would be a further question in what form that volatile organic matter had passed off, and that would be a more difficult question to answer than I had proposed to myself at present.

Mr. Williams: You must bear in mind that the bases do not exist in vegetables as such. The principle does not exist as conia until an alkali is added, when it is developed; and I should very much doubt if the salt of conia would be volatile, as you seem to think.

Mr. Schacht: That is the question I want to solve.

Mr. Catford: A few weeks ago I exhausted a residue of succus by distilling it in the usual way with water, supersaturated with acid, evaporating and distilling with caustic alkali, and I prepared about half a drachm of conia from the mass supposed to be exhausted. I should like to know whether the conia does all go out with the succus, or whether it may not exist in the solid form crystallized in the cells of the plant, and so require further treatment than mere mechanical expression. The sample was unfortunately lost, or I would have brought it.

Mr. Umney: I think Dr. Harley's experiments have quite set at rest any doubt we might have had as to the value of Succus conii. Speaking from memory, I believe that gentleman experimented on himself, and took Succus conii to the amount of ten or eleven drachms per day, until it had such an effect upon his legs that he could scarcely lift them. I have found since his paper was published that the consumption of extract of conium has been getting less and less every year, and that Succus conii has been gaining in favour. The president has referred to the experiment of a French chemist, showing a combination of albumen with alkaloids. It seems to me that a considerable quantity of albumen would be precipitated by the addition of the alcohol ordered in the B.P. process; Mr. Schacht therefore, I would suggest, must not lose sight of this point in continuing his experiments.

The President: I think the combination referred to was of the albumen coagulated by heat, which is not the same thing.

The next paper read was—

Notes upon Chinese Pharmacy in Hong Kong.

BY ARTHUR HUNT.

From the unpretending character of the establishments wherein the various articles of Chinese materia medica are stored and dispensed, European foot passengers would ordinarily pass them by; they have no bright coloured show-bottles in their windows (in fact their windows as a rule are quite guiltless of glazing), no attractive placards, none of the multitude of curious, pretty, and well-arranged articles which in England go to make up the usual well-known chemist's window; neither have they the familiar odour which greets us here as we pass the door. But the not unfrequent music of the pestle and mortar attracts the attention, and appears to invite a brother chip to enter. Before leaving the mixed crowd of odorous Chinese, if at sundown, the observer would be struck by the little brightly smouldering joss-sticks placed on a sort of altar in a small niche generally built exposed to the street on one side of the doorway. This sort of service to their good fortune the Chinese seldom if ever neglect. Perhaps it would be interesting to mention how the little joss or god sticks are manufactured. They are about ten inches long and about half the thickness of an ordinary tobacco-pipe stem, and for one-third their length have been rolled in a composition of well-kneaded cows-dung and sandal-wood powder; when finished and dried, they resemble bull-rushes in miniature, although not so dark. If lighted at the upper end, the composition continues to glow until it is all consumed, giving off a not unpleasant smoke, and leaving a whitish grey ash. The manufacture of these and others of various sizes gives employment to a great number of persons.

The internal arrangements of a Chinese pharmacy are very much as we might expect; a counter runs frequently on either side the store, as it does with us. An assortment of cheap, dark-glazed, and sometimes curiously-shaped jars serves to keep a variety of messes in, some of which, of a dark colour and apparently unfathomable nature, greatly offend the European by their abominable odour. A set of some two dozen drawers answers the purpose of keeping the retail and dispensing stock of cut and dried roots, herbs, &c. A few bottles may also be noticed, but no formidable show is made of them.

Passing by the retail counter with its dreamy assistants towards the little sanctum in the rear, one may catch a glimpse of the style in which the business is conducted. Here is one pigtailed, almond-eyed individual with shaven crown, dressed in blue, busy at the books. He holds his brush-like pen not in a sloping, but perfectly perpendicular manner, and ever and anon smears the point of his pen with ink from a small wet ink palette (in other words takes a fresh dip). The ink is solid, and is known here by the name of Indian ink; it lies near at hand, and to replenish his inkstand he merely rubs the ink stick a few times upon the ink palette moistened with a little water. Here is another cutting up roots; he slices them beautifully, for the Chinese are proverbially skilful at this branch of the pharmacist's art; when the required quantity is obtained, he places it upon a very shallow bamboo sieve or drying tray, and, adjourning to the back yard, or the top of the house, or the front street, exposes the slices to the heat of the sun, in some instances very cleverly and patiently tossing them about until sufficiently dried. A third, probably the dispensing assistant—the major associate—is conning a prescription, which is a curious and somewhat imposing-looking document, written in the vernacular upon a thin dirty-looking piece of paper. Having made himself master of its contents, he proceeds to dispense it. He places upon the counter a piece of coarse paper, and weighs in order, with his steelyard-like scales, the various drugs mentioned in the prescription, and on the weighing of the usual eight or twelve ingredients being completed, all the drugs are wrapped in one parcel, tied up with twisted paper or grass, and the direction either written upon the parcel or verbally given to the patient,—the latter on account of the inability of Chinese females to write or read. The majority of the prescriptions order only vegetable drugs, and very frequently the dispenser most carefully and neatly wraps each individual drug in separate papers, which in some cases are differently coloured. The scales above mentioned have only one pan and one sliding weight, the graduated rod or beam serving to mark very accurately the desired quantity; being, in fact, as nearly as possible like our own steelyards. The observer in a Chinese pharmacy would readily notice the entire absence of those neatly labelled and capped bottles of medicine, in all stages of their preparation, which is so characteristic of our own pharmacies.

The Chinese pharmacist, in common with nearly all traders, takes apprentices, who are bound for several years; they in turn taking their position as assistants or masters, as circumstances permit.

Going further, we reach a small room partitioned off from the shop by scroll or lattice-work, gaudily gilded and somewhat artistically decorated with gaping-mouthed dragons. In this little space of four or five feet square, a consulting room, in fact, which is always attached to a Chinese pharmacy, we may observe a blue-habited, venerable, bearded man. By the way, I am informed that the Chinese do not consider themselves entitled to wear the beard until they are grandfathers; which I am inclined to think is a polite way of saying they could not grow a respectable beard at an earlier period of their lives. The doctor sits by the side of a dark wood table with marble top, upon which a soft cushion is placed: this serves as a rest for the wrist of the small-footed lady who is seated opposite to him. The elderly Celestial is intent upon her pulse: he continues his observations for several minutes, chatting every now and then. Having made his diagnosis, which he does almost entirely by the pulse, he writes a prescription, and it is handed to the dispenser; the result is, the lady leaves the establishment with a parcel of drugs such as described above to infuse or boil.

In the Chinese pharmacies may be found very many carefully-dried herbs, roots, etc. Rhubarb, which they call "Wong Tai" or Great Yellow, and liquorice root, appear to be decided favourites in their prescriptions. Also the ginseng root, turmeric, salep, cubebs, camphor, Chinese cinnamon, coriander, fennel, assafœtida, yellow dog fern roots, and sea-horses, with many other bitter, astringent, laxative, and mucilaginous substances. Alum is largely used in one form or another. Lime, which they principally obtain from shells, is used by them in combination with other things as an outward application. Small pearls, when very finely powdered, are looked upon as very precious for their healing properties. The sea-horses mentioned above are very numerous in the China Sea, and are esteemed as a remedy in debility and consumption; when caught are pickled in salt and water until they become black, and when wanted are boiled, and the decoction reserved for use. The head of this singularly shaped fish greatly resembles that of a horse; they are from four to eight inches long, and two or three good specimens may be seen in the Crystal Palace Aquarium. Sandal-wood, which is very extensively used as incense and for the manufacture of carved and other ornamental boxes, is called by them "Tarn Heong," the oil from it "Tarn Heong Yow." This oil has some considerable reputation among them for its efficacy in restraining mucous discharges. Oil of peppermint, called "Pok Hoo Yow," and peppermint camphor, called "Pok Hoo Ping," are both used extensively, the former most so. The latter is a curious substance which separates from oil of peppermint under certain conditions. It is white, floats on water, is nearly transparent, and has a warm peppermint and camphoraceous taste, and it occurs in small, slender pieces, somewhat resembling large crystals of sulphate of magnesium.

Although these and some other essential oils may be noticed in the druggists' shops, very many distinct places for their sale may be found, separated from the regular pharmacies. The proprietor of an essential oil shop frequently shares it with another tradesman, which is one of the many curious features of Chinese trade; two or even three distinct trades may be observed in one small shop. The oils are put up in small very thick green glass bottles, holding from ten drops to an ounce or two, and enclosed in neat, attractive little boxes, with the invariable red label. The counter bills in a Chinese essential oil shop are generally printed in blue and red characters on thin white paper; the advertisement setting forth the numerous virtues of the Pok Hoo Yow is frequently embellished with a figure of a dragon on either side of an alembic.

Oil of peppermint is largely used and believed in by the Chinese as an outward application. In headache, for instance, a drop or two applied on either side the head, midway between the eye and ear, is said to relieve the pain. Another favourite remedy is a pitch plaster, the size of a sixpence, placed in the same position.

Besides the regular pharmacist whose establishment we have noticed, another and certainly more conspicuous (though not so numerous) set of druggists may be seen. They keep a sort of herbalist's shop, and supply many kinds of both fresh and dry herbs, roots, &c., and in some of these places a sort of herb poultice composed of bruised and chopped herbs, roots, with coarsely powdered mucilaginous seeds, may be obtained ready made. They also make to order what we should consider the most inelegant and disagreeable-looking plasters and poultices that one can conceive. Pharmacy has also its street representative in the quack, I suppose the respectable shopkeeper would call him. He carries his stock-in-trade about with him, by means of a couple of baskets or boxes, slung one at each end of a bamboo balanced on his shoulder, or he has a small stall like the quacks we see in our country market-places, and I believe is licensed by the Hong Kong government as a hawker; he takes his stand under the shade of a friendly tree, a verandah, or clump of bamboos, and soon gathers an admiring crowd, and here may be seen the most loathsome lepers and ulcer-eaten people, upon whom he has probably tried his remedies. The quack speedily puts his hearers into good humour, with his own, but the cash rolls in very slowly (for the Chinese among themselves do everything very cheaply). All the money that the quack takes probably consists of the coin known as cash, each piece being worth about the tenth part of a halfpenny. The Chinese are passionately fond of gambling, and seek it at every turn of their lives; therefore, it is not to be wondered at that they demand that the charm of gambling be added to the purchase of physic. This is very simply and quickly carried out by means of a number of strips of the never-failing bamboo painted all one colour at one end, the other end having a few prize colours interspersed with the blanks; the lower ends are concealed in a jar and the gambler draws a stick. If he is fortunate he may get the full value for his money, but the chances are much in favour of the banker.

The street hawker of medicines sometimes tries his hand, and I may say his nails (which all Chinese wear very long) at dentistry. I saw an old disciple of the above class extract a fine tooth by means of his very long thumb and finger nails; I watched the operation for at least twenty minutes, and it was described to me as elegant dentistry, and a painless extraction.

In regard to the powerful drug opium, which, by-the-bye, is not usually found in pharmacies, the widespread use of it among a certain class of Chinese has led the Hong Kong government to license a few retail shops, and to have them under control. These retail shops do a very brisk trade at all hours; they are supplied with the extract by the wholesale merchants, who manufacture it on a very large scale, adopting a very simple process. All the soluble portions of East Indian opium are extracted by water: by subsidence a clear solution is obtained, which is simply, though carefully, evaporated over wood and charcoal fires in brass pans of the capacity of three or four gallons; a series of these pans are kept fanned and stirred by several coolies; when finished, the extract presents the appearance of very thick dark-brown treacle. To smoke it, therefore, the opium-smoker takes a few grains upon his pipe or stick, and by a few dexterous turns in the flame of an oil lamp placed upon his bed for the purpose, he has the drug dry enough to fume for his most enervating and debasing debauch.

The PRESIDENT: Papers like this, if they are not very useful, tend to enliven our proceedings, and also convey some useful information, and I hope you will accord Mr. Hunt a vote of thanks.

Mr. HANBURY: There is not a great deal to be learned from the pharmacy of the Chinese, but there are one or two things they do to admiration. For instance, they appear to have some clever contrivance for slicing roots, and with their inexhaustible patience they produce a very beautiful article. Another thing I have had an opportunity of observing is the powder of substances, such as carbonate of lime, which, by the aid of elutriation, are obtained in a state of remarkable fineness.

The PRESIDENT: Mr. Hunt referred to the "odorous Chinese." I think I heard or read some time ago that they exhale an odour of musk, or something like that.

Mr. HUNT: They have a peculiar and characteristic oily smell, which it is impossible to describe.

Mr. GILES: It seems easy to believe that different races should be characterized by special odours; a more remarkable phenomenon is attested by persons connected with lunatic asylums, viz., that lunatics exhale a special and characteristic odour which is distinctly recognizable.

Mr. HUNT: Almost all the Easterns have a characteristic smell of their own. I found in travelling that if there were a number of different nationalities collected together, I could recognize a distinct odour to each.

Mr. FRAZER: I am not able to add anything to our scientific knowledge of Chinese pharmacy, but as a visitor to the British Museum I might give some information which even to some London gentlemen may be new. There is in the museum, under the charge of Mr. Carruthers, the contents of a Chinese apothecary's shop, at least 3,000 or 4,000 years old, and many of the roots and leaves are the very same as those now in use, and are in perfect preservation. I may add that Mr. Carruthers would be very glad if any gentleman acquainted with these things would pay him a visit, and assist him to arrange the articles.

"Sessional Prizes."

Sir,—Allow me to occupy a corner in your valuable columns to express the great pleasure with which I have read the letters in your Journal concerning the Sessional Prizes; and permit me, as a sufferer, to point out the manifest injustice of arrangements by which 'a Major man,' who can condescend to compete with a Minor, is enabled to do so, and, as a matter of course, thereby to deprive the latter of the only prize within his reach (the £2 Prize of Books), and that for which his efforts had been legitimately directed.

In days gone by, I am informed that, from motives of etiquette alone, a Major man would never think of competing for this prize; but such times being now unfortunately among the things of the past, should not the Council take steps to remedy the evil and bring back for associates and other beginners their former incentives to work?

A Sufferer.

"Scientific Atheism."

Sir,—Mr. Edwin B. Vizer has denounced in unmeasured terms Professor Tyndall's late address to the British Association, characterizing it as "the sad poison of scepticism," "the poison of rank atheism," which by insertion in it has "contaminated your Journal," and sums up by describing it as "profane and vain babbling, and science falsely so called."

Mr. Vizer's warrant for this wholesale condemnation is that he considers Professor Tyndall's teaching antagonistic to the teaching of Professor Tyndall's Bible. Does Mr. Vizer wish your readers to believe that whenever a declaration of science clashes with a declaration of Scripture, science must be wrong and Scripture must be right? Scripture asserts plainly, unequivocably, that this world, and not this world only, but the universe—the sun, moon, and stars, were created in six days, of twenty-four hours each. No one, who is not more or less a knave or a fool, would attempt to dispute so indisputable a fact. Science, on the other hand, declares that instead of six days, six millions of years would sink into insignificance compared with the utterly inconceivable period that has elapsed since creation's dawn. Scripture likewise declares that from the creation of the first man to the birth of Christ there were but sixty generations, and is so explicit on the point that the name of each individual comprising them is given, and the actual lapse of time deducible from the account is computed to be some 4000 years. Science is again at issue with Scripture, and asserts that the study of geology shows most certainly that it is only less difficult and presumptuous to endeavour to fix the time that has elapsed since man first dwelt on this earth, than it would be to attempt to fix the former period. Which of these utterly antagonistic teachings does Mr. Vizer believe? Possibly—I say *possibly*—he will answer, "that of Scripture;" and if so, will he arrogantly and uncharitably denounce the belief of those who cannot disbelieve the teaching of Science in the matter as "poisonous scepticism"—possibly "atheism"?

Robt. Chipperfield.

Southampton, Sept. 7, 1874.

Sir,—It was with much regret, not unmixed with a feeling of humiliation, that I read Mr. Vizer's letter in your last number on what he is pleased to call "Scientific Atheism."

We are all aware of the howl that has been raised again t Professor Tyndall by a certain section of the community. For that we were not altogether unprepared. We have heard the "pulpit drum ecclesiastic beat with fist instead of stick," but that a member of a scientific body, as we profess to be, should have joined in this outcry, is indeed lamentable.

Your correspondent talks of your columns being "unfortunately contaminated (Heaven save the mark!) with Professor Tyndall's oration." I contend, Sir, that if you had not inserted this magnificent address, you would have forfeited the confidence of the vast majority of the members, and have produced the impression that you had succumbed to a narrow spirit of bigotry, instead of being actuated by a laudable desire for the spread of scientific truth.

I will not be guilty of the presumption of defending the learned Professor, when the only argument Mr. Vizer has attempted to make use of in controverting this "Scientific Atheism," is a quotation from a letter written by Paul, some nineteen centuries ago, and a passage from one of the Psalms of David, which is about as applicable to Tyndall as it would be to the man in the moon.

The most charitable construction one can put upon Mr. Vizer's letter, is, that—like a certain distinguished prelate who raised the cry of heresy against a brother ecclesiastic on account of a work he had written, but was afterwards compelled to admit he had never read it—he has glanced at a few isolated passages and left the main portion unread.

In conclusion, I would advise every young man connected with our Society to read, mark, learn, and inwardly digest this eloquent address, and unless his brain is of a very flabby texture indeed, he will rise from its perusal with a more profound reverence for the great Creator of the universe—a deeper sense of his own ignorance, and a more earnest desire to emulate those distinguished men who, through good report and evil report, are striving manfully to dispel the thick clouds of darkness that for centuries have been hanging over us, and by unfolding those wondrous and unchangeable laws of nature which govern the material world, have invested scientific pursuits with a beauty and a grandeur hitherto unknown.

W. G. Hayward.

Reading, September 7th, 1874.

Sir,—It is not my intention to indulge in a theological argument, which, besides its inappropriateness, would overrun your whole space; neither would I oppose myself to a gentleman whose name I have always heard mentioned with the highest esteem by those who have the pleasure of his acquaintance. Still I can scarcely refrain from thanking you for your excellent report of an address, which is said to have "contaminated" your pages, but which I should have thought would have been hailed by Professor Tyndall's strongest opponents on account of the frank and important admission which he makes, that there is a part of man's nature which science cannot satisfy.

It has been remarked that when men of sense speak strongly there is a strong presumption that the "iron has entered their soul"; and when we hear only the vague (and let us hope, false) rumour that Professor Huxley is likely to quit England on account of the social ostracism which he suffers; when we note the pulpit arguments adduced to crush this moral poison, beginning and ending mostly in the improved *ipse dixit,* "a deceived heart has turned him aside," we cannot wonder at a little manifestation of human nature, but it is not necessary to add a word to Professor Huxley's justly scornful utterances at Birmingham on this point. We cannot but marvel, however, at the palpable tremor of men who profess to be placed on "a rock which cannot be moved" whenever "oppositions of science" dash the spray against its motionless base.

Professor Tyndall admits that there are *creative* as well as *knowing* faculties in man; but shutting himself out from the former, and following his own logical processes and scientific methods, he comes to the conclusion that "like a streak of morning cloud" he will "melt into the infinite azure of the past." His opponents exclude themselves from the latter faculties, and by processes of faith external to science believe that they will "shine as the stars for ever and ever." Both are figurative expressions of an anticipation incapable of accurate definition. Even the cloud that vanishes does not cease to be. Scientists would join issue on the turned leaves of Nature's or Revelation's Book. They boast of a text that is settled which they, *per tot discrimina*, strive to read; but their opponents have not yet settled their text, and should not lightly accuse them of misquotation. Ultimate exposition of either book is not yet rendered, but amongst the difficulties of interpreting Scripture might be found the attempt to establish a relationship between the *ψευδωνυμοι γνωσις* of the apostle and modern science.

As I said, argument is not my object, but a simple protest that on the platform of the "Journal" there is no need for ardent antagonism. Science is impassive—or expends its passion in search after *facts*.

I confess to too much of the emotional to be satisfied with the prospect of *having been* a streak upon an infinite azure (in which language there yet seems to perhaps a wishing ear, despite its sole, sad retrospection, an echo of the "longing after immortality"), but I am content to let my theology lie where the belligerent Scotch divine laid his coat, while I make way for the humane hope (which surely falls short of Infinite Goodness) that something better than ceaseless torture is reserved for those who honestly arrive at wrong conclusions.

HENRY H. POLLARD.

Ryde, I.W., September 7th, 1874.

Sir,—Mr. Edwin B. Vizer seems much exercised in mind as to the baneful effect which the "poison of rank atheism" may have on the readers of this Journal, unless he rushes forward to administer an antidote; not that he has any facts to establish, or arguments to set forth, but merely to guide and re-assure the doubting by reminding them how extremely finite is Professor Tyndall's intellect, compared to that of Job, and how inferior is his method of proceeding to that of the estimable, but somewhat obscure individuals, the Bereans.

The ignorance of Professor Tyndall concerning the First Cause, though not unparalleled, is, doubtless, very dense compared with Mr. Vizer's complacent wisdom; but I may call that gentleman's attention to the fact, that it is not so long ago that a faith as unhesitating and universal prevailed throughout the land as to the existence of witchcraft, and that men quoted in support of that belief, that same Bible that Mr. Vizer is so learned in.

Let me suggest further to him, that the readers of a scientific journal are in duty bound to ignore entirely teleological considerations in these supreme questions, and that there is no antidote to the "poison" which "contaminated" last week's Journal equal to a refutation which the world has yet to receive from Mr. Vizer.

I should also like to know whether he candidly believes that a faithful following out of the example of the Bereans would aid much in the elucidation of mysteries which probably were undreamt of by the men to whose guidance we are referred.

The inscription 'Αγνώστῳ Θεῷ is, *pace* Paul, as true now as it was when written on the Athenian altar, and the spectacle of Mr. Vizer scolding Professor Tyndall, only exemplifies the Greek saying—

Ενεστι κἂν μήρμηκι κἂν σέρφῳ χολή.

H. C. WEBB,

22, *Brook Street, W.*,
August 9th, 1874.

Sir,—I was much surprised on reading Mr. Vizer's letter in the last Journal. I fail to see any ground for his attack on Professor Tyndall.

From beginning to end the Professor studies to be offensive to no one. He states certain facts, draws his own conclusions, and leaves everyone else to do the same.

In both respects Mr. Vizer's letter stands out in ugly contrast. Unable to refute the facts, or explain them, he quotes wildly texts from Scripture, which have as much bearing on the subject as the Lay of the Last Minstrel.

Let him take his own advice to heart. First let him search whether those things are so; and secondly, when he quotes Scripture, let him do it correctly, and not insert in the middle of a sentence his own dogmatisms, and so give to it a meaning the text has not.

WM. G. TAPLIN.

London, Sept. 8th, 1874.

Sir,—With feelings of infinite disgust I read the letter of Mr. E. B. Vizer on Professor Tyndall's address, though why, I can scarcely say, for I think that these ignorant attacks upon Science, under the plea that it is atheism, cannot be treated with too great contempt. But what is there, what single expression is there in the whole of this comprehensive address, that gives Mr. Vizer the slightest reason for attempting to prove Professor Tyndall's disbelief in a Supreme and Omnipotent Being? He considers it atheism to say that "the whole process of evolution is the manifestation of a Power absolutely inscrutable to the intellect of man." Why, this sentence doubly emphasises the Professor's belief in a Supreme Being! Because this address details the formation of man, Mr. Vizer immediately supposes the author to deny the existence of a Divine Power! What must be his own idea of Omnipotence? It must be something like this: a Being possessed of great power, but having to labour, to work like a slave, in order to produce a creature not existing before. Is this grovelling idea comparable to the sublime belief, which no doubt Professor Tyndall holds, that our Maker can create Worlds, can launch forth Systems, by the Power of His Word alone? When Professor Tyndall expatiates on the "differentiation" of man, and so forth, why should this preclude the possibility of a Divine existence? It does not; on the contrary, it emphatically urges the necessity of such existence.

Before Mr. Vizer attempts the renewal of this foolish attack, let him read the concluding remarks of Professor Huxley's address at the same meeting, where these ridiculous fanatics are conspicuously mentioned; and although he can pretty accurately cite Scripture for his purpose,—we have heard of others who can—he forgets that at the very commencement of that Volume we are told, not that God laboured hard and made light, but that God *said*, "Let there be light," and there was light.

SYRUPUS.

September 8th, 1874.

Sir,—While allowing freely the inconvenience of introducing theological subjects or opinions into the columns of the Journal, I would, with due respect, protest, on the other hand, against the doctrine advocated by Mr. Vizer, that on account of what he considers the "poison of rank atheism," such an address as that of Professor Tyndall should be excluded from its pages. On the contrary, I am sure very many of your readers would join me in the expression of gratitude felt that the address was so fully reported.

Mr. Vizer and all who think with him may rest assured that truth cannot and will not suffer from all the philosophies, speculative or inductive, of our scientific teachers, however much these philosophies may play havoc with the non-essential surroundings of truth.

The experiences of the past should teach us to be careful not to do even our little to stifle scientific inquiry, where it is conducted with genuine love for and in pursuit of truth.

It is also painful to see quotations from Scripture, altogether inappropriate, used as the means of introducing harsh epithets and unkind suggestions.

A. P. B.

Bayswater, September 8th, 1874.

[*** The case of Sentiment *versus* Sense has been sufficiently represented by Mr. Vizer and our correspondents of this week, to render the publication of any further letters on this subject admissible. It is satisfactory to observe that the obligations of editorial duty have been recognized by some of the writers, though they do not appear to have been visible from Mr. Vizer's point of view.—ED. PHARM. JOURN.]

W. W.—We cannot recognize the drug, or suggest what plant it belongs to, nor have we been able to obtain any information respecting it.

An Enquirer should apply to the Secretary for a printed statement of the regulations. See also the official advertisement in the journal.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(Continued from p. 84.)

QUASSIÆ LIGNUM.—The tissues of which this wood is composed are somewhat thin-walled minutely pitted wood-cells of the parenchymatous-prosenchyma order, with, intermixed with them, sometimes arranged in bands, thicker-walled but still thin woody parenchyma cells, often containing single prismatic crystals. The medullary rays are composed of one, more frequently two to four, oblong porous cells. The ducts are generally in twos and threes, irregularly distributed, and generally occupying nearly the whole space (laterally) between the rays, their environment of woody parenchyma often pressing the rays out of their direct path. The porous cells round the duct very generally contain prismatic crystals.

As seen in longitudinal radial section, the appearance is as follows, with slight variations as regards their order in different specimens, as the woody parenchymatous bands are irregular in their distribution. *(a)* Bands of woody fibres, thin-walled, oblique, sometimes nearly square ends, minutely porous, and without spiral fibre or very obvious markings of any kind, the pits being very minute. These cells evidently are of the type I have called parenchymatous-prosenchyma, but resemble the prosenchymatous class more than the parenchymatous. *(b)* Ducts and their environment. The ducts are large, closely pitted with small oval pits, often light brown in colour, and square-ended, with frequent septa. They are usually 4 to 5 times as long as broad. The surrounding cells are short pitted cells with somewhat thick walls. *(c)* Bands of woody fibre. *(d)* Bands of woody parenchyma. These are long, thin-walled, porous cells, minutely pitted, and sometimes contain, with granular proteinaceous matter, small prismatic crystals, of which one crystal occupies the cross section of the cell. With these cells are small nearly square cells of the same class, of which each contains one crystal. Then follow bands of woody ducts, etc. It must be noted that this sequence is not invariable, but that the general character of the wood is that it is composed of thin-walled wood-cells with interspersed woody parenchyma, and ducts with crystal bearing cells.

The cells of the medullary rays are about five times as long as broad, are minutely pitted, and contain crystals of the same class as those found elsewhere, but smaller.

PTEROCARPI LIGNUM.—This is a very different type from the last. The cells generally are much more thickened, and their arrangement quite distinct. The structure is that of leguminous trees. Bands of woody parenchyma of considerable width are interspersed with bands of wood fibres. The ducts are single, round, or sometimes double, of moderate size, excepting near the annual rings, where they are very large, and charged with colouring matter. The rays are usually composed of one cell, sometimes of two, and, much less frequently in isolated rays, of 8 to 10 cells. The single celled rays are composed of rather larger cells than the others, and are arranged in perpendicular layers of seldom more than 8 to 10 cells. In other respects than of number the rays are of the same character. The wood-cells are long and narrow, considerably thickened, and minutely porous on the sides nearest the rays or woody parenchyma cells.

The woody parenchyma cells have many points of interest, and are very characteristic. They are of two kinds, one much longer than the other. Both are much thickened, and very distinctly pitted, the pits having very well defined borders. The pits are oblong, or oval and oblique to the length of the cell, and are very much more numerous on two opposite sides of the cells. Frequently on the other two sides, at right angles to the direction of the radius, the pits are nearly absent, and have no borders. This is particularly the case in those cells that approach to the wood-fibres most nearly in appearance. The shorter nearly square cells are the most distinctly pitted, but in other respects resemble the long ones.

The ducts are all porous, with well-defined bordered pits, similar to those of the cells last named. The smaller ducts are rather shorter than the larger, but are otherwise quite similar. The septa in both have frequently been destroyed, and annular *herniæ* show their position. The larger cells show traces of a disrupted spiral fibre, which is sometimes much thickened.

The cells of the medullary rays are generally much longer than broad, and have rounded ends. Some few are nearly circular, and in section parallel with the rays. The cross section of nearly all is oval or round.

GUAIACI LIGNUM.—This wood, as everybody knows, is characterized by its exceeding hardness and toughness. The latter characteristic is explained by the peculiar arrangement of its wood-fibres, which are much thickened, of the true prosenchymatous type, and interlace with each other in a somewhat anomalous fashion. The cross section appearance of the wood is as follows. The wood-cells are small, nearly wholly filled up, and divided into narrow radial bands by the medullary rays, which are usually composed of but one cell. The ducts are single, much thickened, and nearly circular. They are distributed irregularly, but are rather more numerous near the borders of the annual accretions. Examined in detail, the tissues are as follows. *(a)* Wood fibres.—These are long, tough liber-like fibres, distinctly porous, with spindle ends, and more or less curved (like a boomerang); successive formations of this tissue interweave themselves with the preceding, forming an interlaced tissue, which does not readily cleave in any direction. The fibres adhere exceedingly firmly to each other, and the use of strong nitric acid is necessary if we wish to isolate the cells sufficiently for exact examination of them. *(b)* Ducts.—The cells forming these were short, not much longer than broad, and minutely porous. They are much thickened, and coloured by the guaiacum, resin. *(c)* Medullary rays.—These, as has been said consist of one, rarely two cells superposed, in series of 5, rarely more, and are composed of oblong cells with thickened porous walls.

HÆMATOXYLI LIGNUM.—We have here, as in pterocarpus, the structure common to leguminous stems. The cross section is seen to be composed of bands of woody fibres, and woody parenchyma with ducts divided radially by well-developed medullary rays, of which some are much wider than others. In hæmatoxylon the rays generally are much wider than in pterocarpus, and some other stems of the order; and the alternating bands of woody fibres and woody parenchyma have a much more regular sequence in the former than in the latter stem. The minute structure of the various tissues can only be satisfactorily made out in carefully cut sections, after they have had the colouring matter removed. The wood-fibres are pro senchymatous. The cells composing the woody parenchyma are much longer than in pterocarpus, have thinner walls, and are not so conspicuously pitted, and the borders of the pits are smaller as compared with the pits themselves. The squarer cells of this tissue are much more pitted than the longer cells. The ducts are larger than in pterocarpus, they have Bordered pits smaller than in pterocarpus, and sometimes a spiral fibre, single or double, may be seen as a ternary deposit of later formation than the borders. The septa are much thickened, and often imperforate, when they might be mistaken for sclerenchyma cells within ducts. The cells of the medullary rays are unusually long, and have thick porous walls. The structure of the wood appears to be subject to rather fewer variations than pterocarpus.

(*To be continued.*)

AERATED WATER CONTAINING TRIBASIC PHOSPHATE OF LIME.*

BY M. CHEVRIER.

Various considerations led the author to consider the tribasic phosphate of lime to be the best suited for administration where the use of phosphate is indicated. He therefore sought a solvent in which it could be administered without altering its composition. This he thinks he has found in carbonic acid. In fact, he has ascertained by experiment that the bone phosphate dissolves in carbonic acid, and that its solubility augments with the pressure. In order to effect the solution easily and rapidly, it is necessary to use the phosphate in the gelatinous form. On the other hand, however, as aërated waters strongly charged with carbonic acid have a special medicinal action, and might in certain cases be contra-indicated or badly supported by the patients, the author proposes not to exceed the proportion of gas which will dissolve in water under the ordinary pressure of the atmosphere. Under these conditions, a glass of gaseous water will dissolve and retain twenty-five centigrams of tribàsic phosphate of lime, which would appear to be sufficient for a single dose that might be repeated several times a day.

The apparatus necessary for producing this gaseous phosphated water is very simple. Carbonic acid gas produced in the usual way and well washed, is allowed to bubble into a milk of gelatinous phosphate of lime contained in a reservoir. After the passage of the gas for some hours the current is stopped, the excess of phosphate of lime is allowed to deposit, and the clear solution is decanted into bottles similar to those used for natural mineral waters.

The water so obtained is limpid, colourless, and inodorous, and has a subacid flavour. Exposed during several hours to the air, it loses a portion of its carbonic acid and a pellicle forms on its surface. At a later period it becomes turbid. It is, therefore, important to keep bottles that are in use corked, and not to pour out the water long before drinking it.

The presence of basic phosphate of lime in this water may be easily recognized by the following reactions:—

(1.) The phosphated gaseous water is alkaline, a characteristic in which the author considers it differs from all the solutions and syrups hitherto recommended, they having a strong acid reaction.

(2.) Boiling, by driving off the gas causes the precipitation of the basic phosphate.

(3.) Nitrate of silver gives a yellow precipitate of phosphate of silver.

(4.) Ammonia precipitates basic phosphate of lime.

(5.) Ammoniacal sulphate of magnesia causes a precipitate of ammonio-magnesian phosphate.

(6.) Both acetate of urania and molybdate of ammonia give the yellow precipitates characteristic of the phosphates.

The author states that he is convinced that the water, of which the preparation and properties are described above really contains the tribasic phosphate without any mixture of other lime salts, and might be substituted advantageously for the syrups and solutions already in use. It mixes without decomposition with wine, beer, and milk, and consequently can be administered with food—a condition eminently favourable for assimilation.

SOME RECENT EXPERIMENTS WITH A FIREMAN'S RESPIRATOR.*

BY JOHN TYNDALL, D.C.L., LL.D.

In vol. clx. of the 'Philosophical Transactions,' 1870, p. 337, I refer to certain experiments on the "floating matter of the air," which were afterwards considerably expanded, and in part described in my 'Fragments of Science.' These experiments, in which my object was to obtain optically pure air by filtration through cotton-wool, suggested to me the notion of a fireman's respirator. Cotton-wool had been previously employed by Schroeder and Pasteur in their experiments on spontaneous generation.

I had heard that smoke was a formidable obstacle to the fireman, and that cases of suffocation were not rare; hence the desire to construct a respirator. My first trials were made with cotton-wool alone. Associated with the respirator was a mouthpiece with two valves: through one the inhaled air reached the lungs, having first passed through the cotton-wool, while through the other the exhaled air was discharged directly into the atmosphere. The smoke was generated in small rooms, and in some experiments in a cupboard; but though the irritation of the smoke was greatly mitigated by the cotton-wool, it was unbearable for any considerable time.

The cotton-wool was next carefully moistened with glycerine, no clots which could intercept the air being permitted. The respirator was distinctly improved by the stickiness of the fibres of the wool; still, when the smoke was very dense, an amount of irritation continued, which materially interfered with the usefulness of the respirator. Thinking it certain that the mechanically suspended matter would be intercepted by the moistened wool, I concluded that this residual irritation was due to the vaporous hydrocarbons generated during combustion: hence the thought of associating with the cotton-wool Dr. Stenhouse's excellent device of a charcoal respirator. The experiment was successful. With this combination it was possible to remain with comparative comfort for half-an-hour, or even an hour, in atmospheres, a single inhalation of which, without the respirator, would be intolerably painful.

Captain Shaw, of the Metropolitan Fire Brigade, has worked energetically towards the completion of the respirator by associating with it a smoke-cap. Mr. Sinclair has done the same, and he informs me that the respirator is now in considerable demand.

Having heard from Captain Shaw that, in some recent very trying experiments, he had obtained the best effects from dry cotton-wool, and, thinking I could not have been mistaken in my first results, which proved the dry so much inferior to the moistened wool and its associated charcoal, I proposed to Captain Shaw to bring the matter to a test at his workshops in the City. He was good enough to accept my proposal, and thither I went on the 7th of May. The smoke was generated in a confined space from wet straw, and it was certainly very diabolical. At this season of the year I am usually somewhat shorn of vigour, and therefore not in the best condition for severe experiments; still, I wished to test the matter in my own person. With a respirator which had been in use some days previously, and which was not carefully packed, I followed a fireman into the smoke, he being provided with a dry wool respirator. I was compelled to quit the

* *Proceedings of the Royal Society*, vol. xii., p. 359.

place in about three minutes, while the fireman remained there for six or seven minutes.

I then tried his respirator upon myself, and found that with it I could not remain more than a minute in the smoke; in fact, the first inhalation provoked coughing.

Thinking that Captain Shaw himself might have lungs more like mine than those of his fireman, I proposed that he and I should try the respirators; but he informed me that his lungs were very strong. He was, however, good enough to accede to my request. Packing the respirator with greater care, I entered the den with Captain Shaw. I could hear him breathe long, slow inhalations; and after the lapse of seven minutes I heard him cough. In seven and a half minutes he had to quit the place, thus proving that his lungs were able to endure the irritation seven times as long as mine could bear it. I continued in the smoke with hardly any discomfort for sixteen minutes, and certainly could have remained in it much longer.

During this time I was in a condition to render very material assistance to a person in danger of suffocation.

The smoke-cap I wore was one made by Mr. Sinclair, which has a mouthpiece similar to that used in the inhalation of nitrous oxide. But, to show the care necessary in packing the respirator, it is only necessary to remark that, with the packing furnished to me by Mr. Sinclair, it was not possible for either myself or Mr. Cottrell to continue in a dense smoke for more than three minutes; and even these were minutes of laborious breathing. Flannel discs are employed in these respirators, but I cannot recommend them. Cotton-wool, carefully moistened and teased, is, in my opinion, much better.

It is always possible to associate fragments of lime with the respirator, thus, if necessary, intercepting a portion of the carbonic acid. But in most fires we have a more or less free circulation of air; and I venture to think that not in one case in a thousand of actual fires would the combination of smoke and carbonic acid be so noisome as it was in the experiments here described.

THE CARNIVOROUS HABITS OF SOME PLANTS.*

BY DR. HOOKER, C.B., D.C.L., PRES. R.S.

I have chosen for the subject of my address to you from the chair in which the Council of the British Association has done me the honour of placing me, the carnivorous habits of some of our brother-organisms—plants.

Various observers have described with more or less accuracy the habits of such vegetable sportsmen as the Sundew, the Venus fly-trap, and the Pitcher-plants, but few have inquired into their motives; and the views of those who have most accurately appreciated these have not met with that general acceptance which they deserved.

Quite recently the subject has acquired a new interest, from the researches of Mr. Darwin into the phenomena which accompany the placing albuminous substances on the leaves of Drosera and Pinguicula, and which, in the opinion of a very eminent physiologist, prove in the case of *Dionæa*, this plant digests exactly the same substances, and in exactly the same way that the human stomach does. With these researches Mr. Darwin is still actively engaged, and it has been with the view of rendering him such aid as my position and opportunities at Kew afforded me that I have, under his instructions, examined some other carnivorous plants.

In the course of my inquiries I have been led to look into the early history of the whole subject, which I find to be so little known and so interesting that I have thought that a sketch of it, up to the date of Mr. Darwin's investigations, might prove acceptable to the members of this Association. In drawing it up, I have been obliged to limit myself to the most important plants; and with regard to such of these as Mr. Darwin has studied, I leave it to him to announce the discoveries which, with his usual frankness, he has communicated to me and to other friends; whilst with regard to those which I have myself studied, Sarracenia and Nepenthes, I shall briefly detail such of my observations and experiments as seem to be the most suggestive.

Dionæa.—About 1768, Ellis, a well-known English naturalist, sent to Linnæus a drawing of a plant, to which he gave the poetical name of *Dionæa.* "In the year 1765," he writes, "our late worthy friend, Mr. Peter Collinson, sent me a dried specimen of this curious plant, which he had received from Mr. John Bartram of Philadelphia, botanist to the late king." Ellis flowered the plant in his chambers, having obtained living specimens from America. I will read the account which he gave of it to Linnæus, and which moved the great naturalist to declare that, though he had seen and examined no small number of plants, he had never met with so wonderful a phenomenon:—

"The plant, Linnæus says, shows that nature may have some views towards its nourishment, in forming the upper joint of its leaf like a machine to catch food; upon the middle of this lies the bait for the unhappy insect that becomes its prey. Many minute red glands that cover its surface, and which perhaps discharge sweet liquor, tempt the poor animal to taste them; and the instant these tender parts are irritated by its feet, the two lobes rise up, grasp it fast, lock the rows of spines together, and squeeze it to death. And further, lest the strong efforts for life in the creature just taken should serve to disengage it, three small erect spines are fixed near the middle of each lobe, among the glands, that effectually put an end to all its struggles. Nor do the lobes even open again while the dead animal continues there. But it is, nevertheless, certain, that the plant cannot distinguish an animal from a vegetable or mineral substance; for if we introduce a straw or pin between the lobes, it will grasp it full as fast as if it was an insect."

This account, which in its way is scarcely less horrible than the descriptions of those mediæval statues which opened to embrace and stab their victims, is substantially correct, but erroneous in some particulars. I prefer to trace out our knowledge of the facts in historical order, because it is extremely important to realize in so doing how much our appreciation of tolerably simple matters may be influenced by the prepossessions that occupy our mind.

We have a striking illustration of this in the statement published by Linnæus a few years afterwards. All the facts which I have detailed to you were in his possession; yet he was evidently unable to bring himself to believe that nature intended the plant—to use Ellis's words—"to receive some nourishment from the animals it seizes;" and he accordingly declared, that as soon as the insect ceased to struggle, the leaf opened and let them go. He only saw in these wonderful actions an extreme case of sensitiveness in the leaves, which caused them to fold up when irritated, just as the sensitive plant does; and he consequently regarded the capture of the disturbing insect as something merely accidental, and of no importance to the plant. He was, however, too sagacious to accept Ellis's sensational account of the *coup de grâce* which the insects received from the three stiff hairs in the centre of each lobe of the leaf.

Linnæus' authority overbore criticism, if any were offered; and his statements about the behaviour of the leaves were faithfully copied from book to book.

Broussonet (in 1784) attempted to explain the contraction of the leaves by supposing that the captured insect pricked them, and so let out the fluid which previously kept them turgid and expanded.

Dr. Darwin (1761) was contented to suppose that the *Dionæa* surrounded itself with insect traps to prevent depredations upon its flowers.

Sixty years after Linnæus wrote, however, an able botanist, the Rev. Dr. Curtis (dead but a few years since)

* Address to the department of Zoology and Botany of the British Association.

resided at Wilmington, in North Carolina, the head-quarters of this very local plant. In 1834 he published an account of it in the *Boston Journal of Natural History*, which is a model of accurate scientific observation. This is what he said :—"Each half of the leaf is a little concave on the inner side, where are placed three delicate hair-like organs, in such an order that an insect can hardly traverse it without interfering with one of them, when the two sides suddenly collapse and enclose the prey, with a force surpassing an insect's efforts to escape. The fringe of hairs on the opposite sides of a leaf interlace, like the fingers of two hands clasped together. The sensitiveness resides only in these hair-like processes on the inside, as the leaf may be touched or pressed in any other part without sensible effect. The little prisoner is not crushed and suddenly destroyed, as is sometimes supposed, for I have often liberated captive flies and spiders, which sped away as fast as fear or joy could carry them. At other times I have found them enveloped in a fluid of a mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed in it."

To Ellis belongs the credit of divining the purpose of the capture of insects by the *Dionœa*. But Curtis made out the details of the mechanism, by ascertaining the seat of the sensitiveness in the leaves ; and he also pointed out that the secretion was not a lure exuded before the capture, but a true digestive fluid poured out, like our own gastric juice after the ingestion of food.

For another generation the history of this wonderful plant stood still ; but in 1868 an American botanist, Mr. Canby, who is happily still engaged in botanical research, while staying in the *Dionœa* district, studied the habits of the plant pretty carefully, especially the points which Dr. Curtis had made out. His first idea was that "the leaf had the power of dissolving animal matter, which was then allowed to flow along the somewhat trough-like petiole to the root, thus furnishing the plant with highly nitrogenous food." By feeding the leaves with small pieces of beef, he found, however, that these were completely dissolved and absorbed ; the leaf opening again with a dry surface, and ready for another meal, though with an appetite somewhat jaded. He found that cheese disagreed horribly with the leaves, turning them black, and finally killing them. Finally, he details the useless struggles of a Curculio to escape, as thoroughly establishing the fact that the fluid already mentioned is actually secreted, and is not the result of the decomposition of the substance which the leaf has seized. This Curculio being of a resolute nature, attempted to eat his way out,—"when discovered he was still alive, and had made a small hole through the side of the leaf, but was evidently becoming very weak. On opening the leaf, the fluid was found in considerable quantity around him, and was without doubt gradually overcoming him. The leaf being again allowed to close upon him, he soon died."

At the meeting of this Association last year, Dr. Burdon Sanderson made a communication, which, from its remarkable character, was well worthy of the singular history of this plant ; one by no means closed yet, but in which his observations will head a most interesting chapter.

It is a generalization—now almost a household word—that all living things have a common bond of union in a substance—always present where life manifests itself—which underlies all their details of structure. This is called *protoplasm*. One of its most distinctive properties is its aptitude to contract ; and when in any given organism the particles of protoplasm are so arranged that they act as it were in concert, they produce a cumulative effect which is very manifest in its results. Such a manifestation is found in the contraction of muscle,—and such a manifestation we possibly have also in the contraction of the leaf of *Dionœa*.

The contraction of muscle is well known to be accompanied by certain electrical phenomena. When we place a fragment of muscle in connection with a delicate galvanometer, we find that between the outside surface and a cut surface there is a definite current, due to what is called the electro-motive force of the muscle. Now, when the muscle is made to contract this electro-motive force momentarily disappears. The needle of the galvanometer, deflected before, swings back towards the point of rest ; there is what is called a *negative variation*. All students of the vegetable side of organized nature were astonished to hear from Dr. Sanderson that certain experiments which, at the instigation of Mr. Darwin, he had made, proved to demonstration that when a leaf of *Dionœa* contracts, the effects produced are precisely similar to those which occur when muscle contracts.

Not merely then are the phenomena of digestion in this wonderful plant like those of animals ; but the phenomena of contractility agree with those of animals also.

Drosera.—Not confined to a single district in the New World, but distributed over the temperate parts of both hemispheres, in sandy and marshy places, are the curious plants called sundews—the species of the genus *Drosera*. They are now known to be near congeners of *Dionœa*—a fact which was little more than guessed at when the curious habits which I am about to describe were first discovered.

Within a year of each other two persons—one an Englishman, the other a German—observed that the curious hairs which every one notices on the leaf of *Drosera* were sensitive.

This is the account which Mr. Gardom, a Derbyshire botanist, gives of what his friend Mr. Whateley, "an eminent London surgeon," made out in 1780 :—"On inspecting some of the contracted leaves we observed a small insect or fly very closely imprisoned therein, which occasioned some astonishment as to how it happened to get into so confined a situation. Afterwards, on Mr. Whateley's centrically pressing with a pin other leaves yet in their natural and expanded form, we observed a remarkable sudden and elastic spring of the leaves, so as to become inverted upwards and, as it were, encircling the pin, which evidently showed the method by which the fly came into its embarrassing situation."

This must have been an account given from memory, and represents the movement of the hairs as much more rapid than it really is.

In July of the preceding year (though the account was not published till two years afterwards) Roth, in Germany, had remarked in *Drosera rotundifolia* and *longifolia* "that many leaves were folded together from the point towards the base, and that all the hairs were bent like a bow, but that there was no apparent change on the leaf stalk." Upon opening these leaves, he says, "I found in each a dead insect ; hence I imagined that this plant, which has some resemblance to the *Dionœa muscipula* might also have a similar moving power.

"With a pair of pliers I placed an ant upon the middle of the leaf of *D. rotundifolia*, but not so as to disturb the plant. The ant endeavoured to escape, but was held fast by the clammy juice at the points of the hairs, which was drawn out by its feet into fine threads. In some minutes the short hairs on the disk of the leaf began to bend, then the long hairs, and laid themselves upon the insect. After a while the leaf began to bend, and in some hours the end of the leaf was so bent inwards as to touch the base. The ant died in fifteen minutes, which was before all the hairs had bent themselves."

These facts, established nearly a century ago by the testimony of independent observers, have up to the present time been almost ignored ; and Trecul, writting in 1855, boldly asserted that the facts were not true.

More recently, however, they have been repeatedly verified :—in Germany by Mitschke, in 1860 :—in America by a Lady, Mrs. Treat of New Jersey, in 1871 :—in this country by Mr. Darwin, and also by Mr. A. W. Bennett.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 19, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PROVINCIAL ASSOCIATIONS AND PHARMACEUTICAL EDUCATION.

THE presidential addresses delivered before our provincial associations are too often but indifferent productions, which, after the elimination of portions having only special local interest, contain little beyond platitudes to reward the general reader. Frequently, when a formidable roll of MS. is received, bearing the endorsement "President's Address," misgivings arise as to the wisdom of publishing it, and although, as a rule, for the sake of ventilating what might be presumed to be representative opinions, such addresses are placed on record in these columns, it is sometimes necessary to risk wounding the author's *amour propre* by a considerable condensation. It, therefore, is a source of great pleasure to be able to call attention to the address of Mr. W. B. CLARK to the Leicester Chemists' Assistants' and Apprentices' Association, printed in the Journal for last week, and the Report of the Council and Address of Mr. G. F. SCHACHT to the Bristol Pharmaceutical Association, printed at p. 226, this week, as valuable contributions to the history of pharmaceutical education in the provinces.

Whatever else may have been wanting towards the elucidation of the subject of provincial pharmaceutical education hitherto, schemes and suggestions have been put forward in abundance. But how was their practicability to be tested? "Ay, there's the rub!" As the Clothes' Philosopher, Herr TEUFELSDRÖCKH, wisely says, "Between vague wavering Capability "and fixed indubitable Performance, what a differ-"ence! A certain inarticulate Self-consciousness "dwells dimly in us, which only our Works can "render articulate and decisively discernible." Indeed "to render articulate and decisively discernible" the vague shadows set forth by more than one *soi-disant* pharmaceutical statesman would have required a sum of money compared with which the modest accumulated fund that has now and again brought reproach upon the Pharmaceutical Society would have been as the drop of a bucket. Some approach towards the solution of the problem would appear to have been made at Leicester and at Bristol; in the former case by a Society composed mainly of and managed by assistants and apprentices, in the latter by a Society in which the influence of the employers is more predominant. It is only fair to infer, therefore, what has been repeatedly urged in these columns, that it is upon local energy, liberality and tact, rather than to a system of subsidizing by the Pharmaceutical Society, that the future of provincial pharmaceutical education depends. And the Leicester Association affords an illustration of a money grant from the Pharmaceutical Society wisely and readily given and profitably applied.

Although making no pretension to literary merit, the simple narrative of the President of the Leicester Association is full of interest. From the commencement of the Association, in 1869, it seems to have been managed with singular ability and zeal. Although the charm to juniors of managing their own affairs has apparently been now and then broken by inseparable consequent misunderstandings, and perhaps jealousies, there has always been tact and good feeling sufficient to weave the spell again. The consequence has been, that the object for which the Association was established—namely, to help persons employed in the drug trade in Leicester in their preparation to pass the pharmaceutical examinations —has been accomplished, as many as eleven examinations having been passed by members during one half-yearly session; and now, in 1874, the Association boasts the largest number of members it ever had. Moreover, the grant from the Pharmaceutical Society, instead of being dribbled away in current expenses, has been capitalized in the form of a materia medica cabinet. And yet the balance is on the right side of the balance-sheet.

We are glad to believe that the Leicester Association is not alone in its good fortune, but that in other places, and especially at Northampton, a similar success has been attained.

The Bristol Pharmaceutical Association needs no commendation here. Fortunate in possessing among its members pharmacists so distinguished as Messrs. SCHACHT, STODDART, and GILES, and a Secretary so indefatigable as Mr. PITMAN, its evening meetings have acquired a reputation at least equal to those of any held in Great Britain. The same enthusiasm which has marked the catering for these meetings has also attended the educational arrangements made more specially in the interest of the juniors; and, although these arrangements have more of a paternal character than those which obtain at Leicester, the common object has been attained, as is evident from the details given in the report. For instance, seventeen students of the Association entered for the course of lectures on Inorganic Chemistry. Of these, fifteen presented themselves at the end of last session for the Government examination in connection with the Science and Art Department. Thirteen passed, and, in addition, ten succeeded in satisfying Dr. FRANKLAND as to their knowledge of laboratory practice.

These lines have not been written for the special glorification of the societies referred to, but rather to give prominence to the fact that the success of efforts for the diffusion of pharmaceutical education in the provinces cannot be purchased either by local subscriptions or grants of money by a central society alone. A wise discrimination in the selection of proffered services, a persistent personal interest on the part of the members, and the application of the same rules which bring success in ordinary business, each form part of the price that must be paid. It is with regret that we notice that, apparently from overlooking this fact, more than one local Association which once stood in the van remains stationary, or shows signs of decadence, whilst in other quarters where something more than a "vague wavering capability" was felt—or at least asserted—"indubitable performance" is still lacking.

MANCHESTER SCHOOL OF PHARMACY.

We have received a programme of the arrangements, for the session 1874-5, of the Manchester School of Pharmacy, in connection with the Manchester Chemists' Association. There will be a course of thirty lectures on Chemistry, including the elements of physics, delivered by Mr. L. Siebold, on Friday evenings, commencing October 9. Fee 30*s*. A course of twenty-five lectures on Materia Medica and Pharmacy, also by Mr. Siebold, will be delivered on Tuesday evenings, commencing October 6. Fee 25*s*. Mr. Leo H. Grindon will deliver a course of fifteen lectures on Botany, on Friday evenings, commencing October 16. Fee 15*s*. Composition fee, admitting the student to the three courses, £3 3*s*. Application for tickets must be made not later than the 30th inst. In addition, Mr. Siebold will conduct a Laboratory course at his private laboratory, 225, Oxford Street, Manchester. Students wishing to attend this course must communicate with Mr. Siebold before the 20th inst. Further information may be obtained from the Honorary Secretary, Mr. F. Baden Benger, 7, Exchange Street.

LANCASTER MAGISTRATES ON THE APPOINTMENT OF ANALYSTS.

In a report which has been prepared by a Committee for presentation at the next meeting of the Court of Annual General Session for the county of Lancaster, the Adulteration Acts have been considered, especially in relation to the diversity of practice in respect to the remuneration of analysts, and the advisability of making fresh appointments during the present unsettled state of the law. The report recommends a delay. Should it, however, be considered by the court to be inexpedient to delay the appointment of analysts, the Committee advises the appointment of one fully competent analyst for each of the four Quarter Sessional Divisions of the county, exclusive of the boroughs having separate quarter sessions, viz.: Manchester, Liverpool, Bolton, and Wigan, these towns having already exercised their privileges, and appointed analysts of their own. The Committee also recommends that the mode of remuneration should be by a fixed salary or retaining fee to cover laboratory expenses, etc., supplemented by fees for each analysis. If the analyst be required to give evidence in person, the Committee thinks an additional allowance as a witness and a mileage for travelling expenses should be granted, at any rate whenever he is required to give evidence at a distance from his usual place of residence.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual general meeting was held, on the evening of the 7th September, at the Museum and Library, Bristol.

The President, Mr. Schacht, briefly opened the proceedings. He said they would in part be necessarily formal, but that one portion, at any rate, namely the distribution of the prizes to those who had so well earned them, he should be unable to regard simply as a formality. He must commence, however, with the more formal part of his duty, and request their honorary Secretary, Mr. Pitman, to read the report.

The Treasurer, Mr. Boorne, would also read the statement of accounts.

Report of Council for Year ending July 31st, 1874.

The Council of the Bristol Pharmaceutical Association have the pleasure to submit their report of the past year's proceedings.

The plan pursued in previous sessions of arranging a series of evening lectures upon scientific topics of interest to pharmacists was again adopted, and the Association was favoured with some excellent discourses by Mr. Siebold, Dr. Porter Smith, Dr. Watts, Mr. Wills, and Professor Redwood. Your Council are glad to be able to record that this portion of their scheme proved itself as before thoroughly successful.

The evening devoted to reading and discussing original papers was well occupied with good practical matter, and one of the papers, that, namely, by Mr. Towerzey upon Hydrocyanic Acid, has since received a large share of notice in other quarters.

The systematic courses of lectures upon Chemistry and Botany, by Mr. Coomber and Mr. Leipner, were once more repeated with the following results:—

For the course on Inorganic Chemistry, seventeen students of the Association entered, and fifteen presented themselves for the Government Examination at the end of the session. The following thirteen passed:—

Mr. Thos. W. Hall ...	Advanced Grade ...	1st Class.
Mr. Thos. S. Stubbs...	" " ...	2nd "
Mr. C. M. Luxmoore...	Elementary Grade...	1st "
Mr. John Q. Morris...	" " ...	1st "
Mr. Alfred H. Higgs...	" " ...	1st "
Mr. Cuthbert Powell...	" " ...	1st "
Mr. Chas. E. Tritton...	" " ...	1st "
Mr. Walter Powell ...	" " ...	2nd "
Mr. James Lacey	" " ...	2nd "
Mr. John F. Savory...	" " ...	2nd "
Mr. Chas. D. Barker...	" " ...	2nd "
Mr. G. F. Matthews...	" " ...	2nd "
Mr. John H. Hugill...	" " ...	2nd "

The foregoing results relate to the ordinary examinations in Chemistry. The following also succeeded in satisfying Dr. Frankland, the examiner, as to their knowledge of laboratory practice:—

Mr. Thos. W. Hall ...	Advanced Grade ...	1st Class.
Mr. Thos. S. Stubbs...	" " ...	2nd "
Mr. C. M. Luxmoore...	Elementary Grade...	1st "
Mr. John Q. Morris...	" " ...	1st "
Mr. Alfred H. Higgs...	" " ...	1st "
Mr. Cuthbert Powell...	" " ...	1st "
Mr. Chas. E. Tritton...	" " ...	1st "
Mr. John F. Savory...	" " ...	2nd "
Mr. G. F. Matthews...	" " ...	2nd "
Mr. John H. Hugill...	" " ...	2nd "

For the course on Organic Chemistry seven entered, and three presented themselves for and passed the examination:—

Mr. C. M. Luxmoore...	Elementary Grade...	1st Class.
Mr. Thos. W. Hall ...	" " ...	2nd "
Mr. John Q. Morris...	" " ...	2nd "

Mr. Charles M. Luxmoore also passed in laboratory practice.

For the lectures on Botany *eleven* students of the Association entered, and *nine* of these presented themselves for examination. The following passed :—

Mr. Fred. Stamps	......Elementary Grade	...1st Class.
Mr. Charles J. Miles ...	" "	...1st "
Mr. Arthur H. Baldwin	" "	...2nd "

Mr. Stoddart also again gathered together a class for the study of materia medica, and, with the thoroughness that distinguishes him, finished his excellent course of instruction with an examination at which eight of the twelve members of his class competed. The examination papers were kindly supplied and adjudicated upon by Professor Bentley, in whose report, two students, Mr. Cuthbert Powell and Mr. Alfred Higgs, are specially commended. The fees derived from these lectures (twelve guineas) Mr. Stoddart has generously added to the Museum and Library fund, thus making over £37 contributed by him towards this object. These facts speak for themselves; and will elicit, as they deserve, the esteem and gratitude of every member of the Association.

The Council, at the commencement of the session, announced a series of prizes for award to those students who should pass the best examinations in the above-mentioned subjects. They have now the pleasure to state that the following gentlemen have become entitled to these prizes, and they congratulate them heartily upon the distinction they have thus gained.

Mr. Charles M. Luxmoore, for Elementary Inorganic Chemistry.

Mr. Thos. W. Hall, for Advanced Inorganic Chemistry.

Mr. Charles M. Luxmoore, for Elementary Organic Chemistry.

Mr. Frederick Stamps, 1st for Elementary Botany.

Mr. Charles J. Miles, 2nd for Elementary Botany.

Mr. Cuthbert Powell, 1st in Materia Medica.

Mr. Alfred H. Higgs, 2nd in Materia Medica.

The Council have to record and to acknowledge with gratitude an act of great kindness, on the part of a gentleman whose warm interest in the cause of pharmaceutical education is being constantly manifested. Mr. Thomas Hyde Hills, the President of the Pharmaceutical Society, has placed the sum of ten guineas at the disposal of your Council for prizes to be distributed in the manner they think best calculated to promote the educational work of the Association. The decision will be shortly announced, and it is hoped that this sign of sympathy on the part of Mr. Hills with an effort so far removed from his own observation as our school is, will work all the good he so wisely aims to produce.

Your Council cannot pass without notice the recent projection of a scheme for the institution of a College of Science for Bristol and the West of England. The object of your association, namely, the promotion of scientific pharmacy, appeared to your Council to be so closely related to that indicated in the college programme that they did not hesitate to express their cordial sympathy with the effort, and they sincerely hope the course ultimately taken by the new organization will be such as this Association can practically support. Your Council are of opinion that the system of instruction to be offered by this College may be so framed as to include the highest requirements of the student pharmacist.

HILL'S PRIZE FUND.

Received from Thomas Hyde Hills, Esq ...	10 10 0

Examined and found correct,

WILLIAM HENRY COLLINGS.

The President then said it became his duty to move the adoption of the report, which he hoped the members would agree with him in considering fairly satisfactory. They all knew, as he endeavoured to remind them on the occasion of his address at the commencement of their session, that the prime object of the Association was the education of the junior members of their body; and if that purpose had been accomplished to an extent commensurate with their opportunities they were justified in being tolerably content. Referring to the attendance of students at the various courses of lectures, he said that although the list was not quite so large as on some previous occasions, the falling off was but small. He owned he should have preferred to see the numbers increasing rather than diminishing: he must also be allowed to say he should like to see every student who entered for a course of instruction pursuing it earnestly to the very end, and going in, as a matter of course, for the examinations and for the prizes; this would be one of the very best methods his young friends could adopt to show their teachers and the Council that they were as much in earnest as their seniors, and that they appreciated all that was aimed at in their behalf. However, in none of these matters had he any complaint to make, his object was rather to encourage to even greater success in the future than had yet been attained. As regarded one section of their work, namely, the study of botany, he thought it would be the duty of the incoming Council to endeavour to arrange that it should occupy if possible the spring and summer months. He ought not perhaps to be quite silent upon a subject which was not this time mentioned in the report, namely, their being still without a library and museum. The old difficulty, the want of proper premises, still existed, but he was happy to say the extension of the building they were then in had really commenced, and he hoped they might before long see their way to the proper employment of the fund Mr. Stoddart had so laboriously accumulated for this purpose. In the meantime, he would remind them that the Pharmaceutical Society of Great Britain possessed an excellent lending library, a catalogue of which could be had for the asking, and was quite willing to pay the carriage one way of all books that were borrowed by its members and associates. He hoped also they would allow him to say a few words upon a matter which, though alluded to in the report, he did not like to pass in silence; he meant that very kind act of Mr. Hills—the donation of ten guineas towards their prize fund. It was a very rare thing, indeed, to find a gentleman so far removed from personal association with a locality as Mr. Hills was from Bristol, take so warm an interest in that locality's good; it showed a largeness of sympathy as generous as it was rare, and ought to attach every member of their Association to Mr. Hills as a personal friend. He was sorry to have to conclude this portion of his remarks with a shrug, but he must remind them that the balance of their accounts was unfortunately on the wrong side. It was, however, but a small balance, and if each gentleman present would remind his friends that a few more subscriptions would suffice to rectify the blemish, no doubt all would soon be set right; but they must not forget that the effort must be made. In conclusion he begged to move the adoption of the report and the statement of accounts.

Mr. Samson had great pleasure in seconding the motion, which was then carried.

The President then distributed the prizes to the successful candidates, and in doing so remarked that as they were not of very great money value, he hoped those who had earned them would not estimate them solely from that point of view. The purpose of these prizes was to show that the Council took interest in and welcomed their efforts to improve; and they gave them, not so much as rewards for diligence—which might be right when managing children, but wrong when dealing with young men—as signs of the hope that in the successes they were destined to achieve in after-life they would always be able to look back to the studies of the present time with gratification and pleasure.

CHEMISTRY.

Inorganic.—Elementary Grade.—C. M. Luxmoore, 'Attfield's Chemistry,' 'Squire's Companion.'

Advanced Grade.—Thos. Hall, 'Royle's Materia Medica,' 'Bentley's Botany.'

Organic.—Elementary Grade.—C. M. Luxmoore, 'Royle's Materia Medica,' 'Bentley's Botany.'

BOTANY.

First.—Fredk. Stamps, 'Pereira's Materia Medica.'

Second.—Chas. J. Miles, 'Tyndall's Fragments of Science for Unscientific People.'

MATERIA MEDICA.

First.—Cuthbert Powell, 'Cooley's Practical Receipts.'

Second.—Alfred H. Higgs, 'Ganot's Physics.'

Mr. Stoddart supplemented the donations of the Council by some further gifts of his own, and explained that he had not examined his class himself, but had requested Professor Bentley to supply a list of questions, and the papers of the candidates had been afterwards sent to him for estimation. He also bore warm testimony to the attention and courteous bearing of every member of his class, and said he rejoiced in the thought that he had secured them all as personal friends.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A meeting of the above Association was held on Monday, September 14th, for the election of officers for the ensuing session, which resulted as follows:—

President, Mr. C. Hester; Vice-President, Mr. J. Osborne; Secretary and Treasurer, Mr. J. C. Druce; Members of the Council, Messrs. Kemp, Princep, and W. J. Mayger, the latter representing the apprentices. The class conductors chosen were Mr. O. Wallis (Botany and Prescriptions), Mr. J. Druce (Chemistry), Mr. Princep (Materia Medica), and Mr. Osborne (Pharmacy and Latin).

A paper on "Specific Gravity" was sent by Mr. W. Stott, of Leeds, which detailed with great minuteness the different methods of taking the specific gravity of liquids and solids.

Mr. Hester proposed a hearty vote of thanks to Mr. H. J. Masters, who at a former meeting had sent in his resignation as president on account of his leaving the town, for the energy with which he had worked for the Association. Mr. Kemp seconded the vote, and the meeting carried it with much applause.

Mr. Druce then, in the name of the members, thanked Mr. Masters for his services in connection with the Association since its commencement, and expressed their regret at parting with him. He also presented to Mr. Masters a very handsomely illuminated copy of Byron's 'Prisoner of Chillon,' which had been purchased by all the members of the Association.

Mr. Masters warmly thanked the members for their handsome present, which he said he valued not only for its worth and beauty, but also as an expression of good feeling, which he fully appreciated and should always highly esteem. Having thanked the mover and seconder of the vote of thanks for their kind expressions, he referred to the quiet manner in which the Secretary had managed the presentation, as he had not the slightest idea what was going on till the book itself was placed in his hands. He hoped that their next botanical ramble would be near Bedford, so that he might in some way repay the kindness with which he had been treated.

The title-page bore a fitting inscription, and the signatures of all the members of the Association.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from p.* 219.)

SUGGESTIONS RESPECTING THE OFFICIAL AND OTHER CONFECTIONS.

BY T. HAFFENDEN.

Confections are very old preparations. Under the names of electuaries and conserves, this mode of preserving and presenting medicines has maintained a firm position amongst compound remedial agents.

If the confections of the present Pharmacopœia are compared with those of any previous era, I think they will show a decided advance on the crude notions that so long prevailed. Sir Walter Raleigh's confection contained shavings of hartshorn, viper's flesh with hearts and livers, flowers of borage, rosemary, marigolds, sundew and red elder, leaves of scordium, carduus benedictus, baum, cretic dittany, mint, marjoram, betony, juice of kermes, greater cardamom seeds and cubebs, of juniper berries, mace, nutmegs, cloves and saffron, cinnamon, sassafras bark, yellow peel of citron and oranges, aloes wood and sassafras wood, roots of angelica, wild valerian, fraxinella or white dittany, Virginia snake root, zedoary, tormentil, bistort, long and round birthwort, gentian and masterwort; upwards of forty ingredients. This is very far behind our confection of senna, the most complex of our modern confections. Still it is considered that confections need criticism, and I would suggest that the list might be extended.

Confectio Opii.—Is it worth while to class this among the confections? it will not keep any length of time when made. Why not relegate it to the list of powders, as the Pulv. amygd. co., formerly known as Confect. amygd.?

Confectio Piperis.—A substitute for Ward's paste. It seems a useful simple remedy.

Confectio Rosæ Caninæ; Confectio Rosæ Gallicæ.—These are very nice when fresh, but likely to crystallize by keeping; a great disadvantage, as they are very largely used for pill excipients. A sufficient quantity to make a mass is the way they are frequently ordered in prescriptions, the consequence being that according to the age and consistence of the conserve, so is the size of the pills. It has occurred to me whether the addition of a small portion of glycerine in the manufacture of these conserves would tend to prevent crystallization. A great deal of trouble is frequently given to the dispenser by having to incorporate "essential oils" in the masses; the pills sweat and are troublesome to coat. Would it not be worth while to prepare conserves to take to some extent the place of essential oils, in pills; as, for instance, a conserve of lavender, prepared with lavender flowers, sugar, and glycerine, would be a very elegant form of exhibiting a well-known carminative, and the most fastidious lady would not object to swallowing lavender pilules, or a confection of orange would be a very nice form for exhibiting quinine as an electuary, and might even be mistaken for marmalade spread on bread and butter, and given to patients.

With reference to the conserves as excipients, I have not tried the qualities of a proportion of glycerine in arresting crystallization; it seems to me, if we can only manage that matter, it will be better for us, and there will not be the liability, as there is now, to make pills of various sizes in different pharmacies, according to the bias or inclination of the dispenser.

Confectio Scammonii.—This, with confection of senna, is not simple enough for the present time. I would suggest the advisability of having for this class of confections a standard *simple confection*, as a basis for incorporating the active ingredients, in the same way that we have simple ointment amongst the ointments. The composition need only to be extremely simple, the pulp of tamarinds, or prunes with sugar and glycerine, if that proves of any service. Then we might have confections of jalap, scammony, senna, etc. I should imagine a nice aperient confection for children could be made of simple confection, jalap, senna, and ginger combined.

Confectio Sennæ.—The remarks on previous confections apply to this, the more so as this is now frequently in practice made the basis of compound electuaries, containing jalap, sulphur, cream of tartar, etc.

Confectio Sulphuris.—This is a very elegant preparation when fresh made, but apt soon to become disagreeable from pellicles of sugar crystallizing on the surface. This might be advantageously made with simple confection as suggested. In this connection, however, is it wise to ignoref the old family brimstone and treacle? is it quite out o place to give this a standing among recognized formulæ? We are often applied to as to the proper strength to mix this valuable household remedy, and in practice I have found it vary from 1 ounce to 8 ounces to the pound of treacle in different parts of the country.

Confectio. Terebinthinæ.—The last of the authorized confections is, in my opinion, the best. The liquorice disguises the taste of the turpentine most effectually; here it appears to me my proposed Conf. lavand., used instead of the honey, would still more effectually disguise the smell of turpentine, and make a more elegant preparation than it is now.

In conclusion, there are one or two remedies that are found very useful in their action, which are too bulky to be taken in sufficiently large quantity in the form of pills, and yet it is very difficult to exhibit them elegantly in the form of mixtures; such as cinchona, carbonate of iron, guaiacum, etc. These I would suggest might be advantageously exhibited with the simple confection, and find a place in the Pharmacopœia; there is an old form containing guaiacum, called the Chelsea Pensioner, that has been very much used; then there is no Conf. cubebæ; this is very generally in use; in our Brighton Hospital it is used very largely. We make it of powdered cubebs, carbonate of soda, balsam copaiba, and syrup, and find it most useful. I need not reiterate the advantages of having a standard authorized formula for all well-known and largely-used preparations.

A vote of thanks was accorded to Mr. Haffenden.

Mr. Muir's paper on "Potable Water and its Contamination in House Cisterns" was taken as read.

On the Influence of the Means of Supply upon Water used for Domestic Purposes.

BY M. M. PATTISON MUIR, F.R.S.E.

Last year, I communicated to the Conference the results of certain measurements of the action of sewer gases upon water supplied for domestic purposes; from these measurements I inferred that water which comes through the ordinary dwelling-house cistern contains a considerably larger amount of nitrates than water which is supplied directly from the main pipe. As this inference was drawn from an examination of but two samples of water, I have deemed it proper to extend the investigation so as to arrive at results which may be of more general application. The samples have been so selected as to secure the examination of typical waters; some of these samples have been taken from large and well situated dwelling-houses, others from middle-class houses, while others have been supplied to me—through the kindness of the sanitary inspector of Glasgow—from houses occupied chiefly by the lower classes, and situated in the more crowded parts of the town.

The results of the examination are given in the form of a table; all the quantities being stated in *parts per million* of water, which is equal to *milligrams per litre.*

	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.	No. 7.	No. 8.	No. 9.	No. 10.	No. 11.	No. 12.
Free ammonia..	·005	·085	·023	—	·015	·015	·010	·035	·015	·075	·20	·045
Albumenoid ammonia...	·092	·120	·080	·082	·090	·080	·085	·085	·070	·065	·370	·090
Nitrogen as nitrates and nitrites ...	·309	·463	—	·321	·360	·20	·258	—	·284	·306	·414	—

No. 1. From main pipe. No. 2. From cistern in same house; in this house the cistern water is very little used. No. 3. From cistern in house similar to No. 2, but water generally used. No. 4. From pipe leading directly out of the bottom of cistern in well situated dwelling-house. No. 5. From cistern in smaller dwelling-house. No. 6. From small cistern supplying part of a house only. No. 7. From public well, supplied with Loch Katrine water from a wooden cistern closed at the top. No. 8. From cistern situated just under the slates in a house in a lower locality than the preceding houses. No. 9. From cistern over water-closet in a dwelling-house. No. 10. From cistern similar with last. No. 11. Taken from same cistern as No. 9, but after stirring up the muddy deposit at the bottom. No. 12. From cistern near the slates, in a house where there had been two cases of fever, and where the water was complained of.

Omitting for the present No. 11, it is found that No. 2 sample shows the highest numbers for free and for albumenoid ammonia, also for nitrates. Now this sample of water was taken from the cistern of a house in which the pipes have been recently entirely renewed, and in which the pipe leading from the water-closet to the main drain is thoroughly ventilated. The water in this cistern is, however, very rarely used; for all domestic purposes, a supply is obtained directly from the main; it would, therefore, appear that sewer gases are slowly absorbed by water stored in such a cistern.

That this absorptive action must take place slowly is evident, if we look at the results obtained from the other waters. Although many of these waters were taken from badly situated cisterns, yet, in none of them, can the influence of sewer gases be distinctly traced. We must, therefore, conclude that the rapidity with which the water in the cisterns has been changed has prevented any appreciable action of the gases upon these waters. There are, it is true, slight variations in the numbers obtained, but in no case do we find a notable increase as compared with water from the main pipe. The general conclusion to be drawn, therefore, is, that cistern waters are not, under ordinary circumstances, contaminated with sewer gases, but that if the water remains undisturbed for a considerable length of time in the cistern, it may become so contaminated; but that, even in such a case, the amount of contamination is inconsiderable.

House cisterns certainly soon become dirty, and when they have been used for some time, a deposit of mud or slimy matter is found at the bottom.

The amount of ammonia, etc., obtained from a sample of this slimy matter (diluted with the water itself), No 11, indicated that a great part of the ammonium salts, etc., is concentrated therein; this matter may, therefore, perhaps exercise a certain beneficial effect upon the water.

It may be objected to these results that a greater or less amount of free and albumenoid ammonia is not proof of the absorption of sewage gases by water, and that even if these gases are absorbed, their presence will not be indicated by a variation in the amounts of the two ammonias.

In order to test the accuracy of such an objection, the following experiment was performed. A quantity of distilled water, free from ammonia, was placed in a porcelain basin, which was covered with porous paper, and suspended at a short distance above the liquid in a sewer.

Through the kindness of the master of works of Glasgow, I was enabled to conduct this experiment in a sewer which receives the refuse of a very large area chiefly occupied by dwelling-houses. The basin was suspended during 96 hours, after which time the free and albumenoid ammonia in the water was estimated, with the following results.

Free ammonia	= ·60 milligrams per litre	= parts per million.
Albumenoid	= ·54 " "	= " "

Such a water as this would be at once condemned as largely contaminated with sewage. These results show, therefore, that the water has absorbed a large amount of nitrogenous organic matter; and, further, that the exposure of water to the action of sewer gases does very decidedly alter the amount of free and albumenoid ammonia obtained in the analysis of the water.

The conclusions to which these measurements lead me are, therefore, these:—

1. That sewer gases are absorbed by water, and that their presence is rendered evident by an increase in the amount of free and albumenoid ammonia, and also of nitrates, obtained from that water.
2. That this absorption takes place slowly.
3. And that in ordinary cisterns the water is not contaminated to any extent with sewer gases, probably because of the short time during which this water is allowed to remain in the cistern, and also perhaps because of the deposition of part of the impurities in the muddy substance which settles at the bottom of the cistern.

———

Professor Attfield: I may state that this paper of Mr. Muir's is a continuation of the one he read last year. If you remember, he found that water kept in the cistern of a house contained a considerably larger quantity of nitrates than water taken from the main of the same house, and he explained that result on the assumption that the water had absorbed large quantities of sewer gas, which had become oxidized, and so yielded nitrates. In the paper he has now sent, he states that that conclusion was the result of only two experiments, that he has since made ten or a dozen, and he finds that the increase in the quantity of nitrogenous nitrates, caused by possible oxidation of sewer gas, is much less than those two experiments had led him to suppose.

The next paper read was:—

Note on some Indigenous Tuscan Remedies.

BY HENRY GROVES, FLORENCE.

Herbalism in Tuscany is by no means rampant, nor has it been so for two or three centuries. This is to be attributed to the early establishment of hospitals, some of which were kept by monks. Now, these good friars, wise in their generation, knowing with what tenacity the sons of the soil hold fast to their coin, even the smallest, fostered the habit of taking their contributions in kind, and made yearly quests of wine, oil, and corn; so the countryman became identified with his hospital, and left herbs to take care of themselves.

To do justice to the contadino, he is not altogether an apostate from the ancient state of things, for he is withal a practical man, and seeks, therefore, to heal lesser ailments by wedding the curative with the culinary art; so he prepares numerous salads and fried meats with several of the *Cichoraceæ* which he finds on his own grounds, and which are reputed to be useful for this or that disease. There are, however, a few simples to be found in the cupboard of every housewife; for what could be done without the capitula of *Matricaria Chamomilla*, which are used as a calming antispasmodic, and also applied hot externally as a means of relieving pain? Then there are the flowers of mallow, violet, lime, orange, and elder; the leaves of mallow, orange, walnut, and myrtle; with the soboles of couch grass and the roots of marshmallow, and a few others, varying in different districts. But with the foregoing enumeration we have by no means got to the end of our tether. For if housewives in general refuse to enlarge their indigenous remedies, and trust to tamarind for diarrhœa, tamarind for constipation, and tamarind for every other ailment,—tracing all disease to "riscaldimento" or heat, in the same way as we English ascribe not a few disorders to "bile," and the French to "glaires,"—there nevertheless are people who have a much more extensive materia medica, either obtained by observation or handed down to them as the shreds of an almost extinct herb-wisdom which flourished under the worthies of the fourteenth and fifteenth centuries, when medical practitioners identified themselves with research on indigenous remedies more than is the fashion in our day. A custom very prevalent in Tuscany is the administration of herb juice in the spring. It is prepared daily by many herbalists, and is also ordered by the faculty, and thus comes under the notice of pharmacists. The recipes that have come under my notice are varied, but two of the favourites are the following:—

℞. Beccabunga (Veronica).	℞. Ortica.
Nasturtio acquatico.	Bardana.
Fumaria.	Fumaria.
Cochlearia (officinalis).	Gallio (Salium).

Simple chicory juice is frequently used, and that of the nettle is highly esteemed. To all these succi it is usual to add a grain or two of Ferri amm. chlor. or a few grains of sulphate of soda, and sometimes a drachm or two of compound syrup of rhubarb. The treatment is usually continued for a month, and the quantity taken is from three to four ounces of juice per diem. Of the herb-lore of the people, alas! little else than the monsters and griffins of the plant-world remain. The story of the mandrake still opens the eyes of little and big children, as some wise one tells of the dreadful power of the *Mandragora superiora*, of its long and slow growth, and of its deadly power over those who seek to uproot it. An old herb-collector whom I employ, thanks God that when he discovered a mandrake it proved to be a false one, or he should have been a dead man!

In continuing this paper, I shall arrange such simples as I am aware of in their natural orders, so as to get them in some sort of shape. But before proceeding with the plants, let me observe that viper-broth is gone out of fashion, and the pharmacist is spared keeping those reptiles, and the pincers with which they were handled. Snail poultices are still used in the country. The snails are applied alive, the shell being crushed, or partially removed, and the snails set upside down on a piece of coarse paper; they are then sprinkled with a little vinegar, and applied at once to the soles of the feet, on which they produce an irritation greater than mustard, and which is supposed to be efficacious in some cases of fever.

To continue with the herbs, I will begin with the *Ranunculaceæ*, where we have *Aquilegia vulgaris*, used as a diaphoretic in doses of two to four grains, *Pæonia officinalis* as antispasmodic, *Ranunculus sceleratus*, when bruised, as a blistering agent. The hellebores are gone out of fashion, and *Aconitum Napellus* is supplied by the gardens—our indigenous aconites, *A. Lycoctonum* and *A. Cernuum*, not being used to my knowledge.

The *Nymphæaceæ* give a remedy for piles in the root of *Nymphæa alba*, but the difficulty is, that you must first get at the root, although the plant is extremely common in all our marshes. The remedy is used both as an electuary and an ointment.

Papaveraceæ yield *Papaver Rhœas*, called "rosalacci," used in lozenges and syrup for coughs. *Chelidonium majus*, L., is used for wart curing, by means of its acrid juice. The root is also a drastic purgative.

Fumariaceæ give us *Fumaria officinalis*, L., very much employed for making herb-juice and syrup, which are supposed to be of service as depuratives.

The *Cruciferæ* give us several remedies, not the least used being *Nasturtium officinale* R.B., known as "crescione," which enters into the composition of herb-juice, with *Cochlearia officinalis*, which is cultivated for that purpose, although indigenous. *Cochlearia Armoracia* is also used, like the two foregoing, as an antiscorbutic remedy, in the form of syrup. *Bunias Erucago*, L., *Lepidium latifolium*, L., have also been used as purifiers of the blood. *Cheiranthus Cheiri*, known as "Viole gialle," or yellow violets, are employed to make an oil, by simply boiling the flowers in olive oil, and is much used for enemata.

The *Violaceæ* give us two plants very much used, the first being the flowers of *Viola odorata*, called "mammole," which make an excellent expectorant infusion, and the second the *Viola tricolor*, called "pacea," which is used as a gentle cathartic in cases of infants' milk crusts. Its root, like that of the odorous violet, possesses emetic properties.

The *Polygalaceæ* yield us *Polygala amara*, used as an expectorant and tonic in chest diseases, and is prescribed by physicians.

The *Linaceæ* yield us *Linum usitatissimum*, now naturalized; from the seeds of which is prepared freshly an oil which is used as a laxative in many diseases of the liver, in cases of gout, worms, etc. When freshly prepared it is used in North Italy for salad dressing.

The *Malvaceæ* have always been a favourite order with herbalists. The decoction of fresh and dried mallow-leaves (*Malva sylvestris*) being used most frequently, as also poultices of the leaves themselves. *Althæa officinalis*, L., *Lavatera arborea*, L., with *Hibiscus roseus*, Thor., and *Sida Abutilon*, Bert., are all employed in a similar way as demulcents, but more locally.

Tiliaceæ yield the famous lime-flowers, which are the produce of *Tilia Europæa*, Vitm. The warm infusion of these flowers being very useful as a sudorific; moreover the taste is very agreeable, and it has been given to children instead of tea. The distilled water of lime-flowers is also extensively used as a vehicle for other medicines.

The *Aurantiaceæ*, although not indigenous, are now so extensively cultivated in most parts of Italy that they cannot be passed over without notice. In Tuscany, with the exception of the bitter orange (*Citrus vulgaris*), which is more hardy, the different species are cultivated in large vases, which in winter are kept in "stanzoni" or large sheds, to protect them from the frost. The distilled waters of the fruits of *Citrus medica*, or cedro, as well as *Citrus Limonum*, are much used as sedatives, and the leaves of *C. vulgaris* and *E. aurantium* are much employed in infusion, the taste of which is very agreeable, and which is reckoned to be tonic and calming. The flowers of both the bitter and sweet orange, and the distilled waters from them, are all used extensively as sedatives.

The *Hypericaceæ* have their representative in *Hypericum perforatum*, from which an oil is prepared by boiling in olive oil, and which is used externally for worms.

The *Ampelideæ* yield us the vine, from the young shoots of which the tears are collected, and used as eye-lotion. The taste is almost imperceptibly astringent.

The *Rutaceæ* have at least two representatives, *Ruta graveolens*, Sav., and *R. angustifolia*, Pers., which are used internally for worms. The latter species, which grows on barren hills, especially near the coast, is the one more generally employed.

The *Rhamnaceæ* give us the jujube (*Zizyphus sativa*, or *Singiolo*), now naturalized in some places. The fruit is used for demulcent decoctions, and enters into the much-used "Siroppo Inglese" or English syrup, which is used for children's coughs. The berries of *Rhamnus catharticus* are used for preparing a syrup for dogs, but in many districts is unknown.

The *Anacardiaceæ* yield us *Pistacia Lentiscus*, L., from the berries of which an oil is prepared which is used for frictions, but also as a simple burning oil.

The *Leguminosæ* yield but few medicinal plants in comparison with their numbers, which in Tuscany is very great. *Lupinus albus*, L., yields seed which, when ground, is used for poultices, also internally for worms; it is also used to wash with, as a cosmetic. *Melilotus officinalis* is used as an anodyne. The roots of *Ononis spinosa* are diuretic and officinal. I cannot find that *Colutea arborescens*, L., or *Galega officinalis*, is now used medicinally. The meal of *Trigonella Fœnum Græcum* seed is used as a resolvent poultice. In former times it was much employed in oil (Olio di mucillaggini), and ointment (Unguento d'Arceô).

The *Rosaceæ* have many remedial representatives. *Prunus Lauro-cerasus* takes first place, the distilled water being very much employed, chiefly for internal use. The flowers of *Amygdalus Persica*, L., are used for preparing a syrup which, if prepared by a cold process, possesses sedative properties, and has the taste of the syrup of Virginian cherry bark. The fruit stalks of the cherry are used as a diuretic. The roots of *Geum urbanum*, called "Gariofilata," are used as a febrifuge and astringent. The fruits of *Rubus Idæus*, which grows in mountain woods, but is not cultivated, are used for a flavouring syrup; but blackberries, called "More di Macchia," yielded chiefly by *Rubus discolor*, Weih and Nees, are employed more than any other remedy as a syrup. It is very useful for gargles and mouth-washes. The leaves of the bramble are used in decoction for relaxed sore-throats. *Potentilla reptans*, L., called "Pentafillo," and *P. Tormentilla*, are used for staunching blood. The decoction of *Poterium Sanguisorba* is used for washing wounds. The flowers of *Spiræa Ulmaria*, a rare plant in Tuscany, have been used as a diuretic in dropsy.

The *Granateæ* give us the useful *Punica granatum*; the rind of its fruit, and more especially the bark of its root, are used for tape-worm, and with very great success. The bark of the root should be fresh to produce effect. A syrup is also made of the fruit, but it is seldom used.

The *Myrtaceæ* yield us *Myrtus communis*, a very common plant on stony ground, especially near the coast. Its leaves are used in powder as an astringent for dusting babies. The distilled water of the leaves and flowers is sold at the cheap rate of 5*d.* per half-gallon flask, and is much used as a corroborative lotion for the toilet of ladies.

Of the *Cucurbitaceæ*, *Ecbalium elaterium* Reich. takes first place. It is common enough in waste places, near the shores of lakes or by the sea, but in Italy its use is very slight. The seeds of *Cucurbita maxima* and *C. Pepo*, which are extensively cultivated but not indigenous, are used for expelling tape-worms, and to my knowledge are effectual in doses of not less than four or five ounces of the peeled seed. A dose of castor-oil is given prior and subsequent to the dose of seed.

In the *Crassulaceæ* the juice of *Sempervivum tectorum* found in mountain rocks, and cultivated on tiles, is used for aphtha. It has also been employed for epilepsy in the same way as another of this order, *Cotyledon umbilicus*, Dec., has been used in England.

The *Umbelliferæ*, which in southern climates have so many vigorous and striking members, yield a fair share of remedies, *Conium maculatum* being one of the principal. Its extract is used in ointment for the reduction of hard swellings, and is frequently united with iodide of potassium. The leaves are used with good effect as a poultice, and now and then conia is prescribed. *Crithmum maritimum* is used as a diuretic. *Œnanthe Phellandrium*, Lam., yields fruits which have been much lauded for pulmonary complaints; they have a very strong and distinct smell, and possess sedative and carminative properties. The preparations are the tincture and the infusion. Dose of the seed, from five to ten grains. *Fœniculum officinale*, All., with its two varieties "*piperitum*" and "*dulce*" are used as stomachics; the green fruits of the latter are much eaten with bread as a condiment. *Fœniculum dulce* is only found in gardens, whereas *F. officinale* grows on dry hills in many parts of Tuscany. These two varieties require study and experimental cultivation, being so different from the mother plant as to suggest two different species. *Opoponax Chironium*, Koch, which is found in several parts of Tuscany, is said by Savi to yield gum at Piombino.

In the *Loranthaceæ*, both *Viscum album*, L., or ("Visco") and *Loranthus Europæus* or "Visco quercino" are sparingly employed as demulcent decoctions.

In the *Caprifoliaceæ* both the fruit and flowers of *Sambucus nigra* and *S. Ebulus* have been used as sudorifics, drunk in warm infusion.

Of the *Rubiaceæ*, two or three species of *Galium* are employed, such as *G. verum*, L., called "Gallio" or "Caglialatte," from its property of turning milk, used as an antispasmodic and diaphoretic. *Galium Mollugo*, L., for the gout. *G. cruciata*, Scop., called "valanzia," is used as a depurative in herb juice, although the earlier and similar *G. vernum*, Scop., is most frequently used instead.

The *Valerianaceæ* yield us the root of *Valeriana officinalis*. Some of the mountain valerians, such as *V. montana*, L., *V. saxatilis*, L., and *V. Saliunca*, Ten., have roots possessing great strength of odour, and probably have the same value as the officinal plant, but are unused.

The *Compositæ* of course give many remedies. Our old friends, *Tussilago Farfara*, *Inula Helenium* and *Arctium Lappa* are used for the same purposes as in England. The tops of *Achillæa millefolium* are used as a stomachic, and, in some places, both *A. Ageratum* and *A. tomentosum* are used for the same purposes. *Santolina pinnata*, the prettiest of all our santolinas, an exclusive habitant of our Carrara Mountains, is used by the quarrymen as a vulnerary, in the form of oil, poultice, etc. *Matricaria chamomilla*, L., is the camomile employed by the Italians, and to them indispensable. It is used as a carminative in infusion, and the flowers are frequently sprinkled over charcoal pans for the purpose of giving a grateful odour throughout the house. *Artemisia Absinthium* is frequently used as a bitter, *A. camphorata* as a stomachic, and *A. vulgaris* as an alterative. *Tanacetum vulgare* is used, in infusion, for worms. The seeds of *Cnicus benedictus*, L., have been used as an emetic. The leaves of *Cichorium Intybus*, L., are much used for herb juice, and the wild plant is one of those which enters into the "field salad" together with the tender plants of *Zacintha verrucosa*, *Hyoseris radiata*, *Taraxacum officinale*, *Picris hieracioides*, and several species of *Crepis*, and on the sea-coasts, *Picridium vulgare*. The leaves of *Leontodon Taraxacum* are used, but the root is not employed by the Italians; it may be on account of the difficulty of obtaining them, as the herb-gatherers have a decided preference to things growing above ground, and thus more easily obtained.

The *Vacciniece* furnish us with *Vaccinium Myrtillus*, L., *V. uliginosum*, L., and *V. Vitis-idæa*, L., the leaves of all of which have been used for the same purposes as *Uva ursi*, which in Tuscany is extremely rare.

The *Ericaceæ* give us *Arbutus Unedo*, called "albatro," from the ripe fruit of which a spirit called "Corbezzoli" is distilled, and also vinegar is made.

The *Jasmineæ*, with the olive and manna ash, are too well known to require description. but it yields other medicinal plants. The bark and young shoots of *Phillyrea vulgaris*, Caruel, called "Lillatro," which grows plentifully in our fever-stricken maremma, are used as a febrifuge, and its alkaloid phillyrine is also employed in doses double that of quinine. The plant is supposed to increase the quantity and quality of milk when eaten by cattle. Excellent sweet oil can be prepared from the ripe berries of privet, but a friend of mine who experimented upon them told me that they did not pay the expense of collecting.

In the *Apocyneæ*, the leaves of *Vinca minor*, *V. media*, and *V. major* have been used as diaphoretics and astringents.

The *Asclepiadaceæ* yields the once famous *Vincetoxicum officinale*, now almost disused.

The *Gentianeæ* of our Tuscan mountains do not reckon amongst them *Gentiana lutea*, although I have found it much further south in the Abruzzi. In the herb-shops of the "Semplicisti" one finds the so-called lesser gentian, which is yielded by *G. Asclepiadea*, and also probably by *G. cruciata*, both of which have large roots, and are of frequent occurrence in our mountain pastures. *Erythræa Centaurium* and *Menyanthes trifoliata* are both used as bitters; the latter is a rare plant with us.

In the *Convolvulaceæ* the root of the *Convolvulus Soldanella* has been employed as a purgative.

The *Boragineæ* supply us with *Borago officinalis*, now used more as a potherb than as a remedy. The root of *Symphytum officinale* is used as a tonic, and as a cooling application to wounds. *Pulmonaria officinalis* is used for its mucilaginous properties. *Cynoglossum officinale* gives its name to a famous pill-mass, which contains the powdered root and extract of opium, in the proportion of a tenth of each, besides other ingredients.

The *Solanaceæ* yield us *Henbane*, *Belladonna*, *Dulcamara*, and *Stramonium*. From the green leaves of the two former an oil is made by boiling in olive oil until the leaves become crisp. These oils are much used for frictions.

In the *Scrophulariaceæ* we use the flowers of *Verbascum Thapsus* and allied species, for making expectorant infusions. *Scrophularia nodosa* and *S. peregrina* have been used for scrofula, but have few believers now. *Gratiola officinalis* is now very rarely employed as a purgative for worms. Our supply of digitalis leaves is derived from cultivated plants, as *Digitalis purpurea* is not indigenous. The so-called lesser digitalis, or *D. lutea*, is a very common plant, and is sometimes employed. *Veronica Beccabunga* is one of the favourite plants for herb-juice, and frequently *V. Anagallis* is mixed with it.

The *Acanthaceæ* yield us *Acanthus mollis*, which, when more plentiful than it is now, was much used as an emollient for clysters. The leaves and root were both employed. Now the plant has become rare.

In the *Verbenaceæ*, *Verbena officinalis*, called "Erba Santa," is used boiled in vinegar, as a poultice for liver complaints. It is also taken internally for the same purpose, and for dropsy. The seeds of *Vitex agnus castus*, slyly called "Pepe pei Monaci," are supposed to have cooling properties.

The *Labiatæ* contain a host of aromatic plants, which give a distinct odour to our barren hills, especially under the fierce sun of summer. The following are used as carminatives:— *Mentha rotundifolia*, *M. Pulegium*, *Origanum vulgare*, *Thymus Serpyllum*, *Satureja hortensis*, *S. montana*, *Micromeria græca*, *Calamintha parviflora*, *C. arvensis* and *C. Elinopodium*, with *Melissa officinalis*. *Salvia officinalis* makes a very useful decoction for sore throats. The leaves of rosemary, with cypress cones, are boiled in wine, and used for washing weakly children. *Nepeta Glechoma* is used as a strengthening and alterative infusion, *Teucrium Marum* as an emmenagogue, *Marrubium vulgare* for coughs, and *Ajuga Chamæpitys* as a tonic.

The *Plantagineæ* give us *Plantago lanceolata*, which is used for making a distilled water used for the eyes. This water had a reputation for staunching blood. *En passant* I may mention that there is a water distilled wholly from herbs, according to its author, Dr. Capodieci, of Naples, which possesses the property of coagulating blood in a greater degree than Ferri perchloridum. I have seen it employed with the best success, and it has also been extensively used by Professor Schiff, who reports it as a wonderful and most useful invention. What can it be?

The *Thymeleæ* have as representatives *Daphne Laureola*, *D. Gnidium*, and *D. Mezereum*, all of which have been employed for blistering purposes, the bark being macerated in vinegar. *Daphne Mezereum* alone is used internally in weak infusion for syphilitic complaints.

In the *Aristolochiaceæ*, *Asarum Europæum*, *Aristolochia Clematitis*, with *A. rotunda* and *A. pallida*, have all been used as emmenagogues, but now very rarely employed.

The *Urticaceæ* yield us hemp, the seeds of which are employed in emulsion for irritation of the bladder. The leaves and shoots of *Humulus Lupulus* are reputed to be an alterative tonic. Two or three species of *Urtica* are used for making herb-juice, such as *Urtica membranacea*, *U. urens*, and *U. dioica*; the first is the most employed, as the mania for herb-juice takes us in early spring, when the first mentioned is in full flavour. The fruits of *Ulmus campestris* at the latter part of June are filled with a mucilaginous fluid, sought after by the country people as a vulnerary. The leaves of *Juglans regia* are extensively employed in Tuscany, frequently for making astringent injections, or as extract taken in pills as a tonic and depurative.

In the *Amentaceæ* the bark of *Salix alba* is used in decoction, but more frequently its alkaloid is prescribed. The buds of *Populus nigra* are used to make Unguentum populeum, used for piles. This ointment keeps very well for years, thanks to the preservative quality of the balsam contained in the poplar shoots, which moreover have been used in decoction for coughs.

In the *Coniferæ*, *Taxus baccata* has been employed instead of digitalis, in doses of eight to sixteen grains, but I have never seen it prescribed. The fruits of *Juniperus communis* are much used in extract, which frequently enters into the composition of tonic elixirs. The country people make a decoction of the berries in wine for colds and rheumatism. The cones of *Cupressus sempervirens*, as mentioned before, are boiled in wine for making a strengthening application for children. *Pinus pinea*, L., of which large tracts exist in Tuscany, mixed with *Pinus pinaster*, yields the little almond-like seed called "Pinocchio," which is sometimes emulsed as the almond.

In the *Amaryllideæ*, *Narcissus pseudo-narcissus* has been used as an antispasmodic, the bulb and the seed being little employed, but a syrup is made of the flowers. In large doses it is emetic, and even poisonous.

The *Asparageæ* yield us several medicinal plants: first, *Smilax aspera*, or native sarsaparilla, which grows abundantly on stony hills. The roots of *Ruscus aculeatus* are used as a diuretic, as also those of *Asparagus officinalis*. The asparagus roots found in the shops are nearly always those of *Asparagus tenuifolius*, Lam., a beautiful little species growing plentifully in moist woods round Florence, and possessing the same properties as *A. officinalis*.

In the *Liliaceæ* we have *Urginea Scilla*, which grows here and there on the sea-coast, especially of the islands of the Tuscan archipelago. From the tuberous roots of *Asphodelus macrocarpus*, Viv., called "Porraccio," is made the asphodel spirit in the Maremma.

In the *Colchicaceæ*, *Colchicum autumnale* is very common, and the tincture is sometimes used externally.

The *Aroideæ* give us *Arisarum vulgare*, Pal., the tuberous root being used as an emetic instead of ipecacuanha. The leaves of *Arisarum italicum*, Mill., called "Gicheri," are used for dressing blisters. The roots are eaten by pigs, and, according to Orosi, contain 71 per cent. of starch.

The *Cyperaceæ* yield us *Cyperus aureus*, var. *esculentus*, the tubers of which, called "bacicci," were used for demulcent decoctions. They are no longer cultivated in Tuscany.

The *Graminaceæ* give us *Arundo Donax*, the handsome flag one sees everywhere in Italy, and which supplies us with blinds, fishing-rods, fences, laths, etc., etc. The root of this is much used for removing milk. The infusion of the sobules of *Triticum repens* is also much employed as a diuretic, and an extract made of the same is used as a simple extract for pill masses.

The *Filices* have several representatives, all used more or less for the expulsion of worms. For this purpose *Osmunda regalis*, or "Felce florida," has been used, as well as for a tonic for children. *Ceterach officinarum* and *Polypodium vulgare* have also been tried as vermifuges, but with so little success that they are now out of use. *Adiantum capillus-veneris* is much used in syrup for coughs, and possesses the advantage of an agreeable taste. *Aspidium filix-mas* holds its own here, as everywhere, and its rhizome is frequently used in powder.

In conclusion, I may say that the collection of herbs generally takes place, not at some phase of the moon, but on some saint's day. Every plant is supposed to possess its full virtue at that certain epoch, but this does not prevent herb-collectors from securing a good gathering whenever they get the chance, and the saint kicks the beam when weighed against a few centimes.

The PRESIDENT: I am afraid you will consider me a somewhat prejudiced estimator of the value of this paper, the writer being my brother, but still I think I may ask you to pass him a cordial vote of thanks.

The vote was carried unanimously.

Professor ATTFIELD then read a paper—

ON THE ESSENTIAL OILS OF WORMWOOD, CITRONELLA AND CAJEPUT.

BY C. R. A. WRIGHT, D.SC., LOND.,

Lecturer on Chemistry in St. Mary's Hospital Medical School.

I.—Essential oil of wormwood (*Artemisia Absinthium*, L.)—A sample of pure oil yielded the following results on fractional distillation:—

a.—About 1 per cent. was a terpene, boiling at about 150°.

b.—A somewhat smaller quantity was another terpene boiling between 170° and 180°.

c.—The majority was the oxidized body of formula $C_{10}H_{16}O$ (isomeric with camphor and with myristicol from nutmeg oil), termed by Gladstone *Absinthol*. This product was first obtained by Leblanc, and stated by him to boil at 204°; Gladstone subsequently gave the boiling point 217°; the substance examined by the writer boiled at 200° to 201° (corrected); whilst Beilstein and Kupffer have stated, in a paper published whilst these experiments were in progress, that the boiling point is 195°.

d.—A few per cents. were the "blue oils," boiling at 300° and upwards, together with a little of a resinous substance not volatile at 350°.

Absinthol differs from its isomeride myristicol (which boils about 12° or 15° higher) in that it is not appreciably altered in any way by repeated distillation; like this substance it splits up into water and cymene by the action of zinc chloride.

$$C_{10}H_{16}O = H_2O + C_{10}H_{14}.$$

Phosphorus pentasulphide similarly abstracts the elements of water (evolving sulphuretted hydrogen), and produces cymene: simultaneously some cymyl-sulphhydrate, $C_{10}H_{13}.SH$, is formed, apparently identical with that obtained from camphor by a similar reaction.

II.—Essential oil of citronella (*Andropogon Schœnanthus*).—This oil mainly consists of an oxidized substance boiling near 210°, but altered by continual heating, becoming partially resinized, and losing partially the elements of water; this substance gave numbers agreeing with the formula $C_{10}H_{18}O$, which is corroborated by its behaviour with bromine, zinc chloride, etc. Gladstone, however, obtained from this oil a body boiling at 199°—205°, and giving numbers agreeing with the formula $C_{10}H_{16}O$; whence it seems probable that the constituents of an essential oil from a given plant may be subject to variation according to the season, age of plant, soil, etc., etc.

This oxidized product, *Citronellol*, unites with bromine energetically; the resulting dibromide breaks up on heating into water, hydrobromic acid, and cymene.

$$C_{10}H_{18}O + Br_2 = C_{10}H_{18}Br_2O.$$
$$C_{10}H_{18}Br_2O = H_2O + 2HBr + C_{10}H_{14}.$$

Zinc chloride removes the elements of water, forming a terpene, mixed, however, with other hydrocarbons.

Phosphorus pentachloride acts in accordance with the following equation:—

$$C_{10}H_{18}O + PCl_5 = HCl + POCl_3 + C_{10}H_{17}Cl.$$

The resulting chlorinated product breaking up on heating into hydrochloric acid and a terpene together with polymerides of the latter.

$$C_{10}H_{17}Cl = HCl + C_{10}H_{16}.$$

Phosphorus pentasulphide first removes the elements of water, forming a terpene, and then acts on the nascent terpene, converting it into cymene, and evolving sulphuretted hydrogen:—

$$C_{10}H_{18}O + S = H_2O + H_2S + C_{10}H_{14}.$$

Just in the same way, the terpenes of orange peel oil (*Hesperidene*) and of oil of turpentine are converted into cymene by phosphorus pentasulphide, sulphuretted hydrogen being evolved.

$$C_{10}H_{16} + S = H_2S + C_{10}H_{14}.$$

III.—Essential oil of cajeput (*Melaleuca Leucodendron*)—Schmidt has shown that the chief constituent of this oil is a body of formula, $C_{10}H_{18}O$, boiling at about 177°, and hence isomeric with citronellol, which boils about 30° to 35° higher; the product isolated by fractional distillation boiled at 176° to 179°, and gave, with various reagents, results closely analogous to those obtained with citronellol; thus, with bromine, it forms a dibromide, splitting up into water, hydrobromic acid, and cymene on heating; a much larger yield is, however, obtained with oil of cajeput than with citronella oil.

Phosphorus pentasulphide similarly forms, firstly, a terpene, and by further action cymene.

During the above experiments, and those brought before the Conference in former years, sixteen different specimens of cymene have been obtained by one or other process from different substances, all constituents of essential oils, and all either members of the class of terpenes, or closely related to them. The specific gravity, specific refractive energy, and specific dispersion of them have been taken by Dr. Gladstone, all the specimens being found to agree closely together: the boiling point of each specimen has been found to be very close to 176·5° and in every case the action of potassium dichromate and sulphuric acid was the same, viz., the production of terephthalic acid (about 40 per cent. on an average) free from isophthalic acid, and of acetic acid free from all trace of higher homologues. From these results, it is concluded, firstly, that the cymene thus producible is in every case the same body; and secondly, that the terpenes and their derivatives of formulæ, $C_{10}H_{16}O$ and $C_{10}H_{18}O$, are closely related to this hydrocarbon, which may, indeed, be looked upon as the central form of matter from which all these classes of substances are derived.

The President: Dr. Wright's paper is, as usual, of a highly scientific character, and worthy of being termed classical. I am afraid it is above the reach of our criticism, and that we must content ourselves with passing him a vote of thanks.

The vote of thanks having been carried,

Professor Attfield read the next paper, also by Professor Wright:—

New Derivatives from the Opium Alkaloids.

BY C. R. A. WRIGHT, D.SC., LOND.,

Lecturer on Chemistry in St. Mary's Hospital Medical School.

During the past year the following results have been obtained:—

The first product of the action of zinc chloride on codeine was stated by Matthiessen and Burnside to be formed by the abstraction of the elements of water from codeine, and was hence termed "Apocodeine." This observation has, however, been found to be partly incorrect: the first products of the action of zinc chloride are the codeine polymerides described in a paper read before the Conference in 1872, viz., *Tricodeine and Tetracodeine*, the former predominating. Zinc chloride alone does not seem to exert any dehydrating effect on tricodeine; but when heated with hydrochloric acid, this base forms a product apparently identical with "apocodeine," which is, therefore, really a secondary product formed from tricodeine by the removal of six proportions of water.

$$\bar{C}_3 = 6H_2O + (\bar{C} - 6H_2O)$$

may consequently be termed *Hexapotricodeine.*

Experiments on narceine have been commenced; this alkaloid, although so feebly basic that its salts are partially decomposed by water, has nevertheless a strong attraction for a small quantity of hydrochloric acid. When the hydrochloride is crystallized from a liquor containing 8—10 equivalents of hydrochloric acid to 1 of narceine, crystals are formed, of composition $C_{23}H_{29}NO_9,HCl,3H_2O$; the water of crystallization is mostly lost on standing over sulphuric acid (all save about 1 per cent.); on the other hand, the salt dehydrated at 100° gains about 1 per cent. in weight, but no more over sulphuric acid: when dissolved in 50 parts of boiling water, crystals form on cooling, having the composition $6C_{23}H_{29}NO_9 + HCl$; these lose part of the associated hydrochloric acid by long-continued digestion with water; but the whole cannot be thus removed, nor can the base be obtained wholly free from hydrochloric acid, even by precipitation by sodium carbonate, and three successive crystallizations from boiling alcohol; the basic hydrochlorides, $5\ C_{23}H_{29}NO_9 + HCl$ and $10\ C_{23}H_{29}NO_9 + HCl$, recently described by Petit, do not appear to be definite compounds, nor does the last formula indicate the end product of the action of water on narceine hydrochloride, as stated by Petit.

When narceine is heated with excess of strong hydrochloric acid to 100° for an hour, the elements of water are abstracted and a new base formed; this is non-crystalline and yields non-crystalline salts, the hydrochloride being precipitated from aqueous solution in amorphous flakes, by addition of strong hydrochloric acid; physiologically this new product appears to be almost inert, no appreciable symptoms following the subcutaneous injection into dogs and cats of quantities up to two decigrammes; its mode of formation is indicated by the equation—

$$C_{23}H_{29}NO_9 = H_2O + C_{23}H_{27}NO_8$$

the empirical formulæ of narceine and the new product being employed.

The actions of organic acids and their anhydrides on the opium (and other) alkaloids are now under investigation; the following points have been made out:—When codeine is heated with twice its weight of glacial acetic acid, to boiling, for eight to ten hours, an inverted condenser being attached, the majority is converted into *diacetyl codeine*, thus,—

$$C_{36}H_{42}N_2O_6 + 2C_2H_3O.OH = 2H_2O + C_{36}H_{40}(C_2H_3O)_2N_2O_6.$$

This new product is crystallizable from alcohol, ether, benzol, and chloroform, in which it is readily soluble, and from boiling water, in which it is sparingly soluble; a minute amount of codeine is, however, re-formed by the action of the water, by the reversal of the above equation; this action takes place completely when the base is heated to 150° in a sealed tube, containing just enough potash to saturate the acetic acid liberated. The crystallized hydrochloride of this base contains $C_{36}H_{40}(C_2H_3O)_2N_2O_6, 2HCl, 4H_2O$.

When acetic anhydride acts on codeine either at the ordinary temperature for two or three weeks or for an hour or more at 100° or 130°, the same product is formed, no more highly acetylated substance being in any case producible.

Boiling acetic acid acts in the same way on morphine.

$$C_{34}H_{38}N_2O_6 + 2\,C_2H_3O.OH = 2\,H_2O + C_{34}H_{36}(C_2H_3O)_2N_2O_6\,;$$

the base thus formed is termed *α diacetyl morphine* to distinguish it from another isomeride obtained by the action of acetic anhydride on morphine; it is soluble in ether, but cannot be crystallized from ether, alcohol, or benzol, appearing only as a gum or varnish; when precipitated by ammonia or sodium carbonate it is also amorphous; excess of ammonia, potash, or sodium carbonate readily dissolves it. Its hydrochloride is crystalline, and but sparingly soluble in water, as is also the nitrate; the former salt contains $C_{34}H_{36}(C_2H_3O)_2N_2O_6, 2\,HCl, 6\,H_2O$; it gives no colour reaction with ferric chloride.

Excess of acetic anhydride, either at the ordinary temperature or at 100° or 130°, converts morphine into *tetracetyl morphine*, thus—

$$C_{34}H_{38}N_2O_6 + 4(C_2H_3O)_2O = C_{34}H_{34}(C_2H_3O)_4N_2O_6 + 4C_2H_3O.OH.$$

This base resembles diacetyl codeine, being readily crystallizable from alcohol, ether, or benzol, and being but sparingly soluble in excess of ammonia or sodium carbonate; caustic potash, however, dissolves it readily; its hydrochloride is excessively soluble in water, but can be obtained in crystals. Boiling water acts on tetracetyl morphine, forming α diacetyl morphine acetate, thus—

$$C_{34}H_{34}(C_2H_3O)_4N_2O_6 + 2\,H_2O = C_{34}H_{36}(C_2H_3O)_2N_2O_6, 2\,C_2H_3O.OH\,;$$

in sealed tubes at 150° the action goes further, morphine being reproduced.

When morphine is heated to 100° for an hour with just the quantity of acetic anhydride required for the equation,

$$C_{34}H_{38}N_2O_6 + 2(C_2H_3O)_2O = C_{34}H_{36}(C_2H_3O)_2N_2O_6 + 2C_2H_3O.OH,$$

the reaction thus indicated takes place; the main product, however, is not α diacetyl morphine, but an isomeric substance (termed *β diacetyl morphine*) differing from the α base in that it yields a blue colour with ferric chloride, and that its hydrochloride is excessively soluble in water and is non-crystalline, its solutions drying up to a gum over sulphuric acid. The ammoniacal solution of the β base deposits morphine on standing; and the hydrochloride deposits crystals of morphine hydrochloride on standing in contact with excess of hydrochloric acid; the base itself is non-crystalline, and is readily decomposed by boiling water, producing morphine. It is especially noteworthy that although both diacetyl morphines are produced by the action of acetic anhydride not in excess, and of acetic acid on morphine, the β base very greatly predominates in the first case, the α base in the second. Butyric acid seems to give a similar pair of butyryl derivatives; these and analogous substances from strychnine, quinine, etc., are now undergoing investigation, as are also many other points suggested by these experiments.

When only a small quantity of acetic anhydride is used, the product is *monoacetyl morphine*—

$$C_{34}H_{38}N_2O_6 + (C_2H_3O)_2O = C_{34}H_{37}(C_2H_3O)N_2O_6 + C_2H_3O.OH;$$

this body very closely resembles β diacetyl morphine; its production affords another proof of the necessity of writing the formulæ of morphine and codeine, $C_{34}H_{38}N_2O_6$ and $C_{36}H_{42}N_2O_6$, instead of $C_{17}H_{19}NO_3$ and $C_{18}H_{21}NO_3$ respectively.

The PRESIDENT: Dr. Wright has been working away for some time at these morphia derivatives, and has achieved many interesting results. I fully expect that in course of time he will light on facts that will lead to very startling conclusions. The amount of labour he spends on these researches is something marvellous. We are all indebted to him for sending his papers to us.

A vote of thanks was passed.

The PRESIDENT read the following paper on "The Preparation of Trimethylamine."

TRIMETHYLAMINE FROM SKATE.

BY T. B. GROVES.

The skate (*Raia Batis*) is a fish endowed with many peculiarities both of shape and substance. It is largely consumed by the poor on the south coast, and in the form of crimped skate is sometimes met with at the table of the rich.

I once, when they were particularly cheap, endeavoured to cure some as Finnan haddocks are preserved. For the first week or so they were well appreciated, but afterwards they acquired an ammoniacal flavour so very pronounced that it was impossible to proceed with them. There was no putridity whatever apparent. On mentioning this to my porter he at once said it was nothing new, they had simply become . . . . . here he used a vernacular expression impossible to ears polite, in which the letters "p" and "s" figured prominently.

On further inquiry I was informed that this peculiarity was regarded by some low-lived gourmets as its crowning excellence; so much so, that it was never eaten until it had been hung up and could be smelt from one end of the ship to the other—"De gustibus non est disputandum."

Having never met with a fish that behaved so singularly, I determined some day to make experiment with it. I was reminded of the circumstance by the introduction of trimethylamine or propylamine, as it has been erroneously termed, into medical practice.

Early in June this year, I received two skate weighing together about eleven pounds. I kept them three or four days till they smelt strongly, then cut them up, and put them into a copper still, with a little water and a lump (about six ounces) of washing soda. (The use of a copper still was of course not advisable, but I had no other that was convenient.) On passing in steam, I obtained a strong smelling distillate, blue in colour, from dissolved copper. This was collected so long as it was worth anything, then neutralized with hydrochloric acid, and evaporated to one pint. The copper was now removed with sulphuretted hydrogen, and the liquid, then further reduced in volume, was redistilled with caustic soda, the vapours evolved being condensed in hydrochloric acid, the recipient being well shaken. The solution, evaporated to dryness to expel excess of acid, was treated with rectified spirit. The muriate of trimethylamine passed into solution, leaving the muriate of ammonia that accompanied it undissolved; of the former I thus obtained six drachms, of the latter about double that quantity. This, considering all things, is, I believe, a good yield, and the relative quantities of the two substances not so disproportionate as they commonly are.

I would caution any one anxious to repeat my experiment, to avoid wearing his ordinary habiliments on the occasion, or he will find his friends strangely indifferent to his acquaintance, and undesirous of his proximity, for a month or two after.

Mr. HANBURY proposed a vote of thanks to the President for his paper, which was at once carried.

Mr. WILLIAMS: I have listened with a good deal of pleasure to this paper, because I have had considerable experience in preparing trimethylamine. I generally prepare it from herring-brine, but sometimes that source is not available, so that last winter I had to prepare a considerable quantity from sprats. I have also used fresh herrings themselves. Of course the trimethylamine produced is more brown when you distil the fish itself, than when you distil the brine. I do not know whether you, Sir, found much impurity when using skate in this way, or whether the distillate came over at first very brown, and had to be purified several times. I found, when using herrings or sprats, that the distillate contained a great deal of tarry animal oil, which gave us some trouble to separate; but that is not the case when using brine.

The PRESIDENT: There was no tarry oil, but there was a small quantity of oil floating, which I separated readily by the filter. The trimethylamine has been re-distilled.

Mr. WILLIAMS: I suppose you find the hydrochlorate of trimethylamine made in this way is not quite solid.

The PRESIDENT: No, not quite. I evaporated it as far as it would go until it lost no further weight, and then poured it into a bottle while hot, and it set into a semi-solid mass, which by shaking I find has become liquid.

Mr. WILLIAMS: By leaving in 10 per cent. of chloride of ammonium you can make it sufficiently solid to dispense and manipulate.

The PRESIDENT: I think I understood you to say you are in the habit of obtaining a much larger yield of ammonia in company with the trimethylamine; it is not so here. Did you use caustic soda?

Mr. WILLIAMS: No; I used caustic lime.

The PRESIDENT: No doubt it was its action upon the albumenoids which produced the excess of ammonia.

Mr. WILLIAMS: I do not know whether you came to the conclusion that the trimethylamine exists not in the flesh of the fish itself, which was my first idea, but I have now come to the conclusion that it probably entirely resides under the scales.

The PRESIDENT: I have not arrived at any conclusion on that point.

This concluded the reading of papers.

PLACE OF MEETING IN 1875.

It was resolved unanimously that the invitation to meet next year at Bristol be accepted.

ELECTION OF OFFICERS.

Professor ATTFIELD then read the following list of officers proposed for the next year. The gentlemen nominated were unanimously elected by the meeting.

President.

THOMAS B. GROVES, F.C.S., Weymouth.

Vice-Presidents who have filled the office of President.

Professor BENTLEY, F.L.S., M.R.C.S., London.
D. HANBURY, F.R.S., London.
W. W. STODDART, F.C.S., F.G.S., Bristol.
H. B. BRADY, F.R.S., Newcastle on-Tyne.

Vice-Presidents.

T. H. HILLS, F.C.S., London.
R. REYNOLDS, F.C.S., Leeds.
CHARLES BOURNE, Bristol.
PETER SQUIRE, London.

Treasurer.

G. F. SCHACHT, F.C.S., Clifton, Bristol.

General Secretaries.

Professor ATTFIELD, Ph.D., F.C.S., 17, Bloomsbury Square, London, W.C.
F. BADEN BENGER, 7, Exchange Street, Manchester.

Assistant Secretary.

R. H. DAVIES, F.C.S.

Local Secretary.

JOHN PITMAN, Redcliff Hill, Bristol.

Editor of the Year-book.

LOUIS SIEBOLD.

Editor of the Transactions.

Professor ATTFIELD.

Other Members of the Executive Committee, 1874-5.

M. CARTEIGHE, London.
R. W. GILES, Clifton.
W. A. TILDEN, Clifton.
C. EKIN, F.C.S., Bath.
T. GREENISH, F.C.S., London.
W. MARTINDALE, F.C.S., London.
F. M. RIMMINGTON, F.C.S., Bradford.
C. TOWNSEND, Bristol.
C. UMNEY, F.C.S., London.

Auditors.

F. ANDREWS, London.
E. SMITH, Torquay.

The PRESIDENT: On behalf of myself I have to thank you for your renewed confidence. It is very complimentary indeed that I should for two years fill the office of President. I assure you I have had a great fight to get out of it, not because I find the duties too onerous, but to give a chance to others who I think ought to aspire to fill the chair, and who I know would fill it much better than I can. However, my proposition was voted revolutionary; it was decided I should remain here, and therefore I can only assure you I will do my utmost to fill the post with something like efficiency.

Mr. SCHACHT: I rise to fulfil a very pleasing duty indeed. Meeting in this house, as we have done on this occasion, it has perhaps appeared to some that we were taking things as a matter of course, and that all the arrangements were the result of the organization belonging to this establishment. For all that, we are very grateful, and we shall express our thanks in a formal manner for the use of this establishment presently. But I must caution you against thinking that there ends our obligation. It is also due to another set of gentlemen who have laboured very hard indeed for our benefit. I allude to the local committee, whose labours have been very arduous, extending over a long time. During the last few days we have all witnessed with what energy they have worked to carry out the arrangements of this meeting. For the splendid hospitality which has been offered us, and which is proposed still further for our acceptance, we must, I am sure, all feel very grateful indeed, and you will therefore allow me to propose:—

"That the best thanks of this meeting be given to Mr. Carteighe, Professor Attfield, and the other members of the local committee for their efforts in organizing the present meeting."

Mr. BENGER: I am very glad to have the opportunity of seconding this resolution. The success of our Conference has always been very largely due to the efforts of the local committees in the towns we have visited, and never have we had greater cause for thankfulness than on this occasion. In coming to the house of the Pharmaceutical Society, surrounded by so many pleasant associations, we expected to have a pleasant meeting; but I am sure we are indebted to the local committee for adding very much to what we expected to find here, and for their thoughtfulness in promoting, in many ways, our comfort and convenience. Although we have come to the end of the business to-day, we have not yet come to the end of the kind offices of the Committee. As you are aware, to-morrow we are still to reap their kindness, and our gratitude is therefore due not only for what is past, but is certainly a "lively anticipation of favours to come."

The resolution having been carried unanimously,

Mr. CARTEIGHE acknowledged the vote of thanks, and took the opportunity to bear testimony to the continued and unwearied exertions of Professor Attfield from the foundation of the Conference to make it successful in every respect. He did really deserve the best thanks of the Conference on that account, for he (Mr. Carteighe) certainly did not know any man who would have worked for ten years in its behalf, as Professor Attfield had done.

The PRESIDENT: The next resolution is:—

"That the most cordial thanks of the Conference be given to the President and Council of the Pharmaceutical Society, for the use of their lecture theatre and other rooms for this meeting, and for the cordiality with which they have welcomed the Conference."

Seeing the manner in which we have been received by the Council and President of the Society, I know you will accord to them a very sincere vote of thanks for giving us the use of this excellent hall, and for all their other kindness. This is, of course, a memorable occasion, for possibly the Conference may never meet here again, seeing that we generally follow about our elder sister, the British Association. It is, therefore, a great occasion, but the President and Council of the Pharmaceutical Society have risen to its level.

The vote was passed unanimously.

Mr. T. H. Hills: On the part of the Council and the members of the Pharmaceutical Society, I may say that they are most pleased to be able to afford you its rooms and to welcome you here. It has been a bright time for the Society to welcome the Conference—a time which perhaps none of us may live to see again. But I can only say, that should anything happen to prevent you carrying out your original design of going to the localities where the British Association meets, the Council and members of the Society will be only too glad to welcome you here.

Mr. Giles: It is now my pleasing duty and privilege to propose a resolution which will give the *coup de grâce* to this meeting. I am about to ask you who have sat with so much pleasure under the presidency of Mr. Groves to express to him, insufficiently as it must necessarily be in any words I can command, your great respect for him and your high appreciation of the excellent manner in which he has conducted the business of this Conference. We all know the high qualifications which he brings to the chair, and we have also seen that he has brought those smaller qualifications which are nevertheless important to the conduct of a meeting, and which have enabled this meeting to pass off, I venture to say, with great *éclat*. He has known how to sit still and courteously listen, and he has known how to give that fillip to the discussion which is occasionally necessary to keep it going. It has been to all of us a source of very great satisfaction to hear that he has consented again to fill the chair; it was a source of great anxiety to me to know what would be the result of the re-appointment of the officers, and whether we should again have the advantage of Mr. Groves's presidency. I am glad to find, however, that he has acceded to the wishes of those who must be allowed to know better than a single individual can what is best for the welfare of the Conference, and I am pleased to think that, when we in Bristol have the pleasure of entertaining the Conference to the best of our humble ability, it will be presided over by one whom we so highly regard and respect. I have to ask you to pass a cordial vote of thanks to the President for the able manner in which he has conducted the business of the Conference.

Mr. Mackay in seconding the motion said, it is not necessary that I should add anything to the clear, comprehensive, and truthful manner in which Mr. Giles has expressed himself in proposing this vote of thanks. Most truly we can all say, if ever there was the right man in the right place, Mr. Groves has been in that position. It is sometimes not an easy thing to gather up the reins of a series of meetings in connection with a scientific society, and it is yet more difficult to do so and guide with the reins the various forces as Mr. Groves has done during the last two days. That he has done so efficiently and well, we all know, and I especially coincide with what Mr. Giles has said with regard to the future, for I consider our Bristol friends are happy indeed in the prospect of Mr. Groves continuing to be President at the meeting there.

Professor Bentley: As the senior Vice-President, it devolves upon me to put this motion to the meeting, which I do most cordially, entirely endorsing everything which has been said by the proposer and seconder.

The resolution passed unanimously, and being briefly acknowledged by the President, the proceedings terminated.

Parliamentary and Law Proceedings.

Fraudulent Use of a Patent Medicine Stamp.

On Wednesday, Sept. 9, Mr. George Herbert Clarke, stated to be "Dr." Clarke, carrying on business in High Street, Shoreditch, vendor of a medicine called "Dr. Clarke's Blood Renovator," attended, at the Worship Street Police Court, upon a summons taken out by the authority of the Inland Revenue Commissioners, Somerset-house, charging him in three counts, set out at considerable length, firstly, with having fraudulently removed a stamp from a bottle of patent medicine after the same had been sold; secondly, with affixing the said stamp, after it had been once used, to another bottle of medicine; and thirdly, with uttering and exposing for sale the said bottle of medicine, with the duty stamp cut from another bottle of medicine after it had been sold and disposed of. Mr. Tillesley, on behalf of the Commissioners of Inland Revenue, supported the summons; the defendant was not represented. Mr. Flowers asked if it was proposed to prosecute upon all three counts, each count representing an offence punishable by a fine of £20. Mr. Tillesley said he was willing to make it one offence, the three offences being committed to one end. The defendant being here asked if he admitted the complaint against him, replied in the affirmative. He knew, he said, that the facts set out in the summons were true, but in explanation said that some time ago a fire occurred on the premises where the medicines in question (from which the label was alleged to have been taken) was sold. Among the bottles destroyed was the bottle from which he admitted the label was subsequently taken. He denied that the bottle was sold, and said that the stamp being intact had been removed to put on a bottle of his own medicine, for which the same duty (3*d.*) as represented by the stamp would have had to be paid. Mr. Tillesley explained the facts of the case. He said that the defendant prepared a medicine known as "Dr. Clarke's Blood Renovator," and a Mr. Clarke, of Lincolnshire, prepared a medicine known as "Clarke's world-famed Blood Mixture." Mr. Clarke, of Lincolnshire, put his name on the Government stamp of his bottles, and the defendant had, in the one instance before the Court, removed the old stamp from a bottle and affixed it to a bottle of his own medicine. Two bottles, stated to have been purchased of the defendant, were then handed up for the magistrate's inspection. One bore a duty stamp as a patent medicine, to which the magistrate's attention was called as the fraudulent using complained of. It was also said that the signature was so imitated as to be a fraud by the defendant. Mr. Flowers observed that the letters were printed alike in blue in each case. The defendant said the stamp taken from the bottle had been erased by his writing over it. Mr. Clarke, of Lincolnshire, was called into the witness-box, and examined the label, which he said had a name written over to imitate his, letters being formed with exact similarity. Mr. Flowers said that as the defendant had pleaded guilty he would mitigate the fine, but he was not allowed to do so beyond a half. He ordered the defendant to pay £10.—*Times.*

A Child Poisoned by Opium.

An inquest has been held at Accrington touching the death of a child named Sarah Ellen Wittam, 16 days old, daughter of John Wittam, labourer. It appeared that the mother after her confinement took some opiate pills to allay the pain, and the baby being unwell, she thought that as the pills had done her good they must have a similar effect on the child. She gave it half a pill containing opium. The effect was to poison the child, which died the following morning. The jury returned a verdict of "Died through the unintentional administration of poison."

Poisoning by Spirit of Salt.

Mr. F. Price, borough coroner, has held an inquest at Salford, touching the death of Anthony Davies. It appeared by the evidence that the deceased was a dealer in old bottles, and was in the habit of purchasing small quantities of spirit of salt for the purpose of cleaning the bottles. Between ten and eleven o'clock, after he and his wife had been drinking, he opened the bedroom window, and shouted to the neighbours to fetch him some water. A neighbour took him some water, and afterwards, hearing the deceased moaning, entered the house and found him on his knees in the bedroom. Deceased told him he had taken some spirit of salt, adding that he should not have taken it if he had known that "it burned so." He was subsequently taken to the Salford Hospital, where he was attended to by Mr. J. H. Morris, the house surgeon, who prescribed the usual remedies. The deceased was then quite sensible and able to walk, but died about five o'clock in the evening. He told Mr. Morris that he took the spirit of salt in mistake, thinking it was whisky. Mr. Morris said that he had ascertained that deceased had taken above an ounce of the spirit of salt, and he had no doubt that death was caused by the dose. The jury returned a verdict of "Death from misadventure, while under the influence of drink."—*Manchester Courier.*

Prosecution for Embezzlement.

At the Liverpool police court, on August 27, two young men were sent to prison—one for six months, and the other for one month—for embezzling money belonging to their late employers, Messrs. Evans, Sons, and Company, wholesale chemists. The embezzled money had been received from Mr. J. Thompson, dealer in patent medicines. It was stated that for trade reasons Messrs. Evans had prohibited their servants selling goods to Thompson; but that he had succeeded in inducing the prisoners to supply him without the knowledge of their employers, and the sale of the things was entered in the books under feigned names. Mr. Mansfield, who heard the case, severely censured Thompson, who, he said, had thrown the greatest temptation in the way of the prisoners, and been guilty of conduct which was "utterly unpardonable."

Review.

The Essentials of Materia Medica and Therapeutics. By Alfred Baring Garrod, M.D., F.R.S., etc. Fourth Edition, Revised and Edited, under the Supervision of the Author, by E. Buchanan Baxter, M.D. Lond., etc. London: Longmans, Green and Co. 1874.

We have before us the first, third, and fourth editions of this work. The first, published in 1855, contains 282 pages. The third, 479; and the fourth, just received, notwithstanding the omission of notices of about a score of obsolete drugs, such as black hellebore, Winter's bark, simaruba bark, carrot, tormentil, elecampane, wintergreen and bayberry, has 517 pages. Enriched, as the work is, by the author's practical experience in therapeutics, this enlargement shows the labour and pains he has taken in furnishing trustworthy information on what is essential for the medical student to know of materia medica and the outlines of therapeutics. The appreciation by the medical profession of its high value as a text-book places it on a level with Erichsen's 'Surgery,' and Ellis's 'Anatomy.' In the present edition, the "Additions to the British Pharmacopœia," recently published, meet with their share of attention, as well as other new remedies lately brought under medical notice, such as croton-chloral hydrate, sulphocarbolate of soda, guarana, coca, tea, *Eucalyptus globulus*, yellow jasmine, condurango, and trimethylamine. Among new remedies, oleic acid and its combinations (excepting oleate of mercury, which is simply mentioned) are conspicuous by their absence. The chemistry and therapeutics of the opium products are brought down to the present time. The results of the investigations—physiological and therapeutical—of Fraser, Crum Brown, and Ringer, on the action of atropine and strychnine are also given.

The therapeutics of the new edition seems to have received special attention, while its materia medica, chemistry, and pharmacy have been neglected; in these subjects it bears the evidence of incompleteness, and a number of errors are carried forward which a careful revision should have checked. For example, in the process given for the making of green extracts, it is stated that "the juice . . . . is first heated to 130° in order to coagulate the green colouring matter, filtered and heated to 200°, at which temperature the albumen is coagulated. After being again filtered to remove the albumen, the juice is evaporated *at a temperature not exceeding* 140°, *to the consistence of a thin syrup*, and the colouring matter, previously separated by the first coagulation, is added, and the whole evaporated to the proper consistence of an extract." The Pharmacopœia permits the full heat of a water-bath to be applied after the separation of the albumen; it is only limited to 140° when the colouring matter is again added, to prevent the decomposition of the latter. Under the head of liniments also, Linimentum iodi is not an exception, but does contain camphor.

Liebig's mode of testing the strength of hydrocyanic acid is erroneously explained in both the third and fourth editions. In the fourth, although some attempt has been made at correction, it is further wrong than ever. On the addition of the silver solution to the acid, rendered alkaline by an excess of soda, a double cyanide of silver and soda is formed, which is precipitated at first, but redissolves on agitation. When all the hydrocyanic acid is withdrawn in the formation of this double cyanide, it is stated: "nitrate of silver gives rise to a precipitate no longer soluble; the appearance of that permanent precipitate of oxide of silver is an indication that all the cyanogen is exhausted. The changes may be exhibited in the formulæ—

$$(AgNO_3 + 2\,NaCy = NaNO_3 + NaAgCy_2)$$

and when no more cyanide is present—

$$(2\,AgNO_3 + 2\,NaHO = 2\,NaNO_3 + Ag_2O + H_2O)"$$

Whereas the first permanent precipitate is white, and is not the oxide of silver, but the true insoluble cyanide of silver. On the addition of more silver solution than will form the soluble double salt, the following equation represents the decomposition:— ($NaAgCy_2 + AgNO_3 = 2\,AgCy + NaNO_3$). If much excess of soda be present, the oxide of silver will also be precipitated, if a considerable quantity of silver solution be used, or added carelessly, but not until all the cyanogen has combined with the silver to form the true cyanide, and any chlorine as well has become converted into chloride of silver, the latter being generally present in hydrocyanic acid as hydrochloric acid, an intentional impurity, which it is thought prevents the decomposition of hydrocyanic acid. The beauty of the B.P. test consists in its not estimating this hydrochloric acid as hydrocyanic acid.

Under the head of tartarated antimony, it is stated that a "watery solution gives a white precipitate of *acid tartrate of potash* with hydrochloric acid, which is not formed if tartaric acid be previously added, as that salt is *soluble* in it." The precipitate is not acid tartrate of potash, but oxychloride of antimony. A question in the second M.B. examination at the London University two or three years ago depended on this test, and the explanation given by Dr. Garrod puzzled a number of the candidates not a little, both before and after the examination. It ought now to have been corrected. Nitrate of silver is directed to be made into a pill with "crumb of bread or some ingredient which does not decompose the salt." As bread-crumb always contains common salt, a more incompatible excipient could hardly have been suggested. Calomel, it is stated, "is blackened when treated with potash, from precipitation of *mercury*." In making ammoniated mercury, the perchloride of mercury is directed to be dissolved in the water, by the aid of heat; "*to* the solution, when it has cooled, *add* the ammonia, frequently shaking it." This will not form the Pharmacopœia white precipitate.

Light oxide of magnesia is a misnomer which has passed two revisions. The following short and simple process and explanation of it is given as that of the B.P. for making chlorate of potash:—"By passing a stream of chlorine gas through a mixture of carbonate of potash and slaked lime; when saturation has taken place, chlorate of potash, chloride of calcium and carbonate of lime are formed; after the carbonate has been removed by filtration, the less sparingly soluble chlorate crystallizes on evaporating the solution ($K_2CO_3 + 6\,CaH_2O_2 + 6\,Cl_2 = 2\,KClO_3 + 5\,Ca\,Cl_2 + CaCO_3 + 6\,H_2O$)." The specific gravity of Liquor sodæ chloratæ in one part is given as 1·06, and below, on the same page as 1·103; this has been overlooked twice. The fresh—not the dried petals, as stated—of *Papaver Rhœas* are official in the British Pharmacopœia. Senna is the leaflet, not the leaf, of *Cassia lanceolata*, etc. The dried as well as the fresh root of *Taraxacum* is official. The botanical source of our rhubarb root is not now undetermined. Castor, it is stated, "contains *volatile oil*, uric, phosphoric, and benzoic acids, combined with potash, soda, and lime; also carbonate of ammonia, *salicine*, *carbolic acid*, and a peculiar principle *castorin*." The italics are not ours, but we are surprised to find that castor contains *salicine* and *carbolic acid*, and wonder how they have been isolated and identified. *Vinum opii* is prepared from the extract now, and, therefore, "1 gr. of opium is contained in 14½ min. of *Vinum opii*," is not correct. Opium lozenges also are prepared from the extract, not from powdered opium. Some corrections, we notice, have been made, but in a text-book a student should have facts. Some of the errors we have mentioned are trivial enough, others, are likely to bring doubt into the mind of the student.

In these days, when it is expected that a medical student can get up all the 'ologies in the short space of our years, this work of Garrod's is perhaps the best published, and specially adapted for the student's use who aspires no higher than "College and Hall." But, shade of Pereira and Christison! We should hope that our Universities require more from their candidates for their M.D. degree than an ex-examiner in materia medica and pharmaceutical chemistry metes out to them—one who disparages arnica, broom, and the sweet influences of tobacco, and cannot find space for a few medicinal dietetic articles, such as arrowroot, tapioca, sago, and tous-les-mois, but yet gives a place to condurango. It is enough to make us turn homœopaths at once. A Huxley may despise materia medica while he is solving biological problems, but the physician must know and have proved the efficacy of his remedies as much as the surgeon the sharpness of his knife. Should, for example, his prescription, on which depends the life or death of his patient, contain, as many do, the vague term Liquor cinchonæ, his patient may get a medicine rich in quinine or entirely devoid of it. The short space which students are required to devote to the study of materia medica and pharmacy—three months to each—may account for the small amount of careful therapeutical as distinct from physiological research done of late years. The Pharmacopœia wants weeding. Our humble opinion is that there are drugs in it less efficacious than arnica, and a redundancy of preparations of others which fill their place in our pharmacies until, when they are wanted, they are found to be effete, and require renewal. Surely there is work for the therapeutist here, if it be only to obtain negative results, to place a number of the above in the Index Expurgatorius, as we hope may be the case in the next edition of our National Pharmacopœia. In conclusion, pharmacists would have to beware if Dr. Garrod had the wielding of the Adulteration Act. "A trace of sulphurous acid" in sublimed sulphur is an adulteration; so is "a little red iodide of mercury" in Hydrargyri iodidum viride; and lime water is "apt to contain carbonic acid"! In fact all impurities according to him are adulterations.

BOOKS RECEIVED.

An Introduction to Pharmaceutical and Medical Chemistry (Theoretical and Practical). Arranged on the Principle of the Course of Lectures on Chemistry as delivered at the South London School of Pharmacy. By John Muter, M.A., F.C.S., etc. London: W. Baxter. 1874. From the Author.

An Elementary Treatise on Practical Chemistry, and Qualitative Inorganic Analysis. Specially adapted for use in the Laboratories of Schools and Colleges, and by beginners. By Frank Clowes, B.Sc., etc. London: J. and A. Churchill. 1874. From the Publishers.

Obituary.

GEORGE EDWARDS.

It is with deep regret that we record the death, on Sunday last, of another old and valuable member of the Pharmaceutical Society, Mr. George Edwards, of Dartford. The connection of Mr. Edwards with the Society dates from 1842, and during twenty-five years of the intervening time he was a member of its Council, having been elected in May, 1847. He was chosen Vice-President in 1855-6, and again in 1871-2. He was also a member of the Board of Examiners for several years. Mr. Edwards was born in February, 1808. He lived at Dartford forty-five years, during nearly the whole of which time he was in business on his own account. For many years he took a prominent part in local matters of various kinds that affected the interests of the town and people of Dartford. He was a leading member of the Wesleyan Society, and a man deeply interested in every good movement. For several years he had been in failing health, and for a year or more quite unable to carry on business, from which he retired some few months since. After a gradual loss both of bodily and mental vigour, he breathed his last early on Sunday morning last, having been seized with apoplexy about three hours previously. The funeral was to take place at Dartford, on Thursday, at three o'clock.

CHARLES SAVORY.

Our obituary for this week has also to include another name well known in the pharmaceutical world, that of Mr. Charles Harley Savory, of the firm of Savory and Moore. The cause of Mr. Savory's death is stated to have been a cystic growth in the brain, from which he had suffered for several months. He died at his residence, Lancaster Gate, on Thursday, August 27, aged 44.

In mentioning the death of this accomplished gentleman, one circumstance must be related to his honour. Though taking no prominent part in the public affairs of the Society, he was ready to render efficient aid whenever his services were required. When it was in contemplation to arrange a series of autograph prescriptions for the use of the Board of Examiners, he at once placed the whole of his transcribed manuscript formulæ at their disposal. It being represented that *copies* were inadmissible, he handed over his private collection, which now forms one of the volumes employed during the examinations. The whole contents of the book were contributed by himself, but the name of the donor was withdrawn at his request.

Notice has been received of the death of the following:—

On the 17th August, 1874, Mr. George Morgan, Chemist and Druggist of Redditch. Mr. Morgan had been a member of the Pharmaceutical Society since 1869.

On the 11th August, 1874, Mr. David Benjamin Jones, Chemist and Druggist, of Cardiff.

On the 23rd August, 1874, Mr. Samuel Smith Chapman, Chemist and Druggist, of South Hackney.

On the 15th July, 1874, Mr. George McIsaac, Chemist and Druggist, of Edgbaston.

On the 31st August, 1874, Mr. Richard Jefferson, Chemist and Druggist, of Malton, Yorkshire.

On the 27th August, 1874, Mr. Edwin Thomas Weaver, Chemist and Druggist, of Kandy, Ceylon. Mr. Weaver had been an Associate of the Society since 1869.

On the 3rd September, 1874, Mr. James Ward, Pharmaceutical Chemist, of Falkingham. Mr. Ward was one of the founders of the Pharmaceutical Society.

On the 2nd September, 1874, Mr. William Freeman Hopkins, Chemist and Druggist, of Henley-in-Arden.

On the 29th August, 1874, Mr. Richardson Appleby, Chemist and Druggist, of North Shields.

At Pwllheli, on the 14th inst., Mr. John Evans, for nearly thirty years the esteemed representative of Messrs. Evans, Sons, & Co., Liverpool.

Correspondence.

The Recent Discussion on Milk.

Sir,—In justice to Mr. Stoddart allow me to remark that from having occasionally met with samples of milk of unusual richness, I had provided against it in page 7 of my pamphlet, where I say that sometimes as much as four or five lines of butter oil may be obtained from 250 grains of milk, but it came from Alderney cows.

Mr. Stoddart in the outset stated as much, for I particularly examined his specimens in the Society's rooms, and observed that his No. 1 tube with four lines of butter oil from 250 grains of milk, was duly marked "Alderney cow's."

The mistake, however, of parties in raising the question was taking 6·64 grains as the average of milk, which Mr. Stoddart never gave.

Now, I have been quoted as giving 3·32 per cent. from two lines of butter oil as the average, but Mr. Stoddart's sample from being so much richer, was just the multiple of mine.

Consequently 1000 grains of milk from Alderney cow, of 20 per cent. cream, will give 66 grains of solid butter, as against 33 from good ordinary milk of 10 per cent. of cream, or just twice the quantity, which confirms Mr. Stoddart's statement.

John Horsley, F.C.S.
Analyst to the County of Gloucester.

Cheltenham, September 14th, 1874.

The Official Plasters.

Sir,—Having read your report of the discussion upon Mr. Gerrard's paper on the "official plasters," perhaps I may be allowed, as a medical plaster manufacturer, to observe that my experience leads me to agree with Mr. Umney in considering the P.L. form for Emp. Plumbi preferable to that of the B.P.

This branch of pharmaceutical preparations does not appear to have engaged the attention of pharmacists in any great degree; consequently, there is not that precision in the formulæ which might be desired, and although with plasters, as with many other of our official preparations for external use, it may be said with truth, that a given formula may be placed in the hands of different manipulators, and as many products varying in appearance, etc., may be the result, yet, *cœteris paribus* the proportions mentioned by Mr. Umney, viz., five litharge to nine of olive oil, and the B.P. form of four parts litharge and nine of oil, give rise to products varying in character both as to keeping and adhesive qualities, and, as I said before—keeping both these points in view, my experience confirms the truth of Mr. Umney's remarks. My desire is to elicit truth, or further discussion, and not to advertize, therefore I sign myself

"One in the Trade."

September 15th, 1874.

Toothache Pencils.

Sir,—Will you allow me through the Journal to call the attention of the trade to the sale of non-stamped toothache pencils. As they are clearly liable to the stamp duty, every chemist having them in stock is liable to a fine.

M. P. S.

W. Symons.—We have received your communication, but feel compelled to adhere, without exception, to the announced determination not to continue the controversy in these columns.

C. H.—All candidates for the Minor Examination will, after October 1, be examined under the new regulations.

W. D. (who should have sent his name and address) will find an article on the subject in the *Pharmaceutical Journal* for March 30 last, p. 953.

A. Ronca.—You would have to wait until you are twenty-one years of age.

J. Mayne.—(1) We are not acquainted with any such process. (2) Wanklyn's 'Water Analysis,' published by Trübner.

"*Libra*" and "*Inquirer*" will find the desired information respecting the metric system of weights and measures in any good modern work on arithmetic.

H. H.—Several formula for lime juice and glycerine have already appeared in the present series of this Journal. See vol. i., pp. 658 and 716.

"*Inquirer.*"—The injustice which you denounce in anticipation will not exist. The phrase, "*the last* three years," is one of your own coining, since the words in italics do not occur in the bye-law. The candidate will simply have to satisfy the examiners that he has been at some previous time for three years practically engaged in the translation and dispensing of prescriptions.

"*Rustic.*"—We think the label would require a stamp, since it implies that the preparation is made according to a secret formula, and also recommends it for various ailments.

Epergne.—Yes.

Errata.—In the report of the meeting of the Leicester Chemists' Assistants and Apprentices' Association, printed on p. 206, *for* "Mr. E. J. Butter" *read* "Mr. E. J. Butler," and *for* "Mr. John Young" *read* "Mr. Joseph Young."

F. J. Attenburrow.—*Artemisia vulgaris.*

G.—*Mentha rotundifolia* and *Aconitum paniculatum.*

E. P.—The plant is *Euphorbia lathyrus.* We should recommend you to send some of the wheat ears to the editor of 'Grevillea.'

J. F. Matthews.—We do not clearly understand your questions. Candidates will be examined in the first four rules of arithmetic, simple and compound, vulgar fractions and decimals, and have to show a thorough knowledge of the British and Metrical systems of weights and measures.

J. Goodwin.—It cannot in any way be considered to be a medicine, and therefore would not be exempt from the regulations applying to Part 1 of the poison schedule.

"*Quintus.*"—The proportion of sulphuric acid allowed by law is as you state. We suppose the prosecutions have been for exceeding that quantity.

G. C.—It would be difficult, if not impossible, to determine satisfactorily the presence or absence of the substances you mention. In any case it would be necessary to submit the mixture to a preliminary chemical examination.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ*. A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

Communications, Letters, etc., have been received from Mr. W. G. Taplin, Mr. C. Ekins, Mr. Clark, Mr. G. Broom, Dr. W. H. Griffiths, Mr. S. M. Challinor, W. D., R. K. K., "Libra," "A Father," "A Victim."

ON THE CAUSE OF DECOMPOSITION OF TINCTURE OF ACETATE OF IRON, B.P.

BY G. WELBORN.

It is well known, to the cost of many pharmacists, that it is utterly impossible to make tincture of acetate of iron by the process given in the Pharmacopœia, so as to obtain a preparation possessing the necessary qualities of definite composition and stability; and, having frequently experienced the difficulty of procuring tincture of ferric acetate, which would retain indefinitely those essential characters, it appeared that a considerable amount of time and attention might be given with advantage in endeavouring to elucidate the cause of decomposition, and the nature of the resulting new products.

It was found that the tincture, prepared strictly according to the Pharmacopœia, remained bright from two to three weeks, or longer, according to the temperature and other causes, of which more will be said below; it then began to assume a gelatinous condition, still, however, retaining its transparency. After this first evidence of change, decomposition was more rapid, and in four or five days more the tincture became opaque and semi-fluid, owing to the separation of a large quantity of a reddish-brown gelatinous precipitate. In this condition it is almost needless to remark that it is quite unfit for dispensing purposes.

With the object, therefore, of discovering the cause or causes of the above changes in the tincture, the following experiments were performed:—

The first step was to make solution of persulphate of iron by the Pharmacopœia formula and process—half the quantities being taken. The colour of the liquid did not change from black to dark brown (after the addition of nitric acid), accompanied with violent ebullition and evolution of ruddy fumes, until its volume was diminished by evaporation to 3 fl. oz.

A drop of the above syrupy persulphate solution was diluted with water, and a little of this diluted solution being tested with ferricyanide of potassium on a white slab, showed that the conversion into the ferric state was complete. The whole was then diluted with water until it measured 5½ fl. oz.

On dilution the colour of the liquid changed from dark brown to ruby red.

A portion of the above solution of ferric sulphate was converted into tincture of ferric acetate; the B. P. process being slightly modified, as follows:—

Seventy-five minims of solution of ferric sulphate, B.P., were mixed with fl. ʒiv. of rectified spirit, and 60 gr. of potassic acetate were added to fl. ʒv. of rectified spirit. As the whole of the acetate did not dissolve in the spirit, a few drops of concentrated acetic acid were added, but the solution still remained alkaline, yet it was rendered perceptibly clearer by the addition of the acid.

The iron and potash solutions were mixed in the usual manner, and the whole thrown on a filter. The liquid ceased to drop when fl. ʒviss had passed through. Rectified spirit was then percolated through the precipitated potassic sulphate until the percolate measured ʒx.

The tincture thus obtained was set aside in a stoppered bottle. In five days a reddish-brown, pulverulent precipitate began to appear, and gradually increased for the next twelve days, when its formation appeared to be arrested. It resembled the hydrated peroxide of iron in colour; but, unlike it, was readily soluble in cold dilute hydrochloric acid. The hydrochloric acid solution gave a blue precipitate with potassic ferrocyanide, and a green colouration only with the ferricyanide. There was not the least appearance of gelatinization in the tincture, and at the expiration of 34 days it presented the characters of a bright, deep ruby-coloured liquid. On the 38th day it had let fall a copious gelatinous precipitate.

A second quantity of 5½ fl. oz. of solution of ferric sulphate was made; but, in this instance, it was evaporated to dryness in a porcelain basin on a sand-bath. During the evaporation dense white suffocating fumes were evolved, having a strongly acid reaction on litmus. When almost dry, and at a temperature approaching that of a red heat, the fumes coming off were unmistakably those of nitric acid. Just previous to this point of the heating process the persulphate was so exceedingly tough and plastic as to be stirred only by the exertion of a considerable amount of force. It was carefully kept under a red heat, as it undergoes decomposition at that temperature. When the salt had ceased to give off any vapours, it presented the characters of a whitish, amorphous residue, with a slight tinge of buff in some of the fragments.

The dry residue was moistened with water, when considerable heat was evolved. About ℥x. of water were subsequently added: it was then placed aside for three hours, and, as scarcely any portion appeared to be dissolved, it was gently heated for three hours longer, when the whole had undergone solution. The solution now measured ℥x.: it was reduced to fl. ℥vss by evaporation.

Seventy-five minims of the latter solution were converted into tincture of ferric acetate, and set aside, as in the former experiment. On the seventh day there was a perceptible reddish-brown precipitate, which slowly increased for seven days, when all further change appeared to cease. The precipitate formed in the latter experiment was about one-fourth that of the previous one, and of similar appearance, neither did the supernatant liquid gelatinize or show any other sign of change in thirty days, but retained the bright, deep-red colour of a good specimen of the tincture. (On the 36th day, however, a bulky gelatinous precipitate separated.) One drop of concentrated nitric acid was added to about ʒj of the latter tincture (free from any precipitate). There was no perceptible change until the seventeenth day, when it had become somewhat gelatinous, and opaque by reflected, but still remained transparent to transmitted light. On the twentieth day about one-half had become a reddish brown, opaque jelly. At this stage it had developed a powerful ethereal odour resembling that of acetic ether. It was treated with a slight excess of solution of potassic hydrate, and set aside for twenty-four hours, filtered, the filtrate evaporated almost to dryness to expel the spirit, the residue diluted with with water, and a portion treated with solution of potassic permanganate, acidified with sulphuric acid. The permanganate solution was completely decolorized.

A second portion of the above potassic hydrate residue was treated with dilute sulphuric acid, which caused a brisk effervescence: the evolved gas had the odour of nitrogen tetroxide. From the fact of the reduction of the permanganate may be inferred the formation of potassium nitrite, and necessarily also, previously that of nitrous ether, or nitrous acid, produced by the gradual decomposition of the nitric acid by the alcohol of the tincture.

A further cause of failure in the Pharmacopœia process arises from the fact of the fused potassic acetate, commonly met with in pharmacy, not being a neutral compound. It was found to be strongly alkaline, both in its aqueous and spirituous solution, owing to the unavoidable expulsion of acetic acid during the process of fusion. Two ounces of potassic acetate, added to fl. ℥x of rectified spirit, yielded an insoluble residue, which was estimated at about 20 grains in weight. A little concentrated acetic acid was introduced through the spirituous solution of acetate, and delivered upon the insoluble matter by means of a pipette, when there was an immediate effervescence. The clear liquid portion was then poured carefully off, and concentrated acetic acid added to the residue until the whole was dissolved, and the acid in slight excess. The alcoholic solution was next returned to the acid liquid, but the whole was observed to become again alkaline, by the bit of reddened litmus paper left in the acid liquid suddenly changing from red to blue.

Now, as potassic carbonate is insoluble in rectified spirit, the alkalinity could not possibly arise from the presence of carbonate, but must necessarily be due to that of hydrate, which is soluble in that menstruum. At least fl. ʒiv of concentrated acetic acid were added before the reaction became faintly acid to litmus paper.

It was also discovered that litmus paper moistened with solution of potassic acetate, then made distinctly red with dilute acetic acid, and exposed to the air for about an hour, changed in colour from red to blue. If the paper be then dropped into dilute acetic acid, bubbles of gas are evolved. It may, therefore, be inferred that potassic acetate in solution is decomposed by the carbonic anhydride in the atmosphere, and converted into carbonate.

The gelatinous precipitate from B.P. tincture of ferric acetate was spread on bibulous paper, pressed, and exposed for ten days to the air in a warm place. It shrank to an exceedingly small bulk compared with that it originally occupied, and was easily rubbed to powder under a knife. The dry precipitate was very slowly soluble in concentrated acetic acid, readily soluble in cold dilute hydrochloric acid to a yellow solution, very slightly soluble in water, imparting a pale, reddish-brown colour, acid reaction, and slightly astringent taste to the liquid. The acetic acid solution gave a green colouration with ferricyanide, and dark-blue with ferrocyanide of potassium. The aqueous solution gave a brownish precipitate and yellow colouration to the liquid with ferricyanide, and a dark-green colouration with ferrocyanide, which immediately changed to dark-blue on the addition of acetic, or the dilute mineral acids.

A little clear tincture of ferric acetate was agitated with a small quantity of well-washed and freshly-prepared ferric hydrate, and set aside for a day. The excess of hydrate did not subside, and the liquid was not obtained in a bright condition after being filtered three times. The ferric hydrate appeared to be held in an imperfect state of solution, which was bright by transmitted, and opaque reddish-brown by reflected light. This condition was only slightly changed on standing seven days, by the gradual deposition of a reddish-brown precipitate. On the thirty-seventh day it had become almost entirely gelatinized, and, as nitric acid was supposed to be entirely eliminated from the tincture, it was clear that the cause of decomposition must be sought elsewhere.

A quantity of tincture of ferric acetate was accordingly prepared by dissolving the requisite amount of ferric hydrate in acetic acid and adding alcohol so as to obtain a tincture of the B.P. strength. By this process the absence of free nitric acid was ensured.

The tincture thus obtained was divided into three portions. Concentrated nitric acid was added to one in the proportion of ♏ 3 to each fl. ʒj. On the fifty-seventh day it remained perfectly transparent, but there was a development of a powerful odour of acetic ether.

The second portion was agitated with washed ferric hydrate, and, after standing eight hours, filtered: the filtrate was bright between the eye and the light, but opaque sideways. On the fourteenth day a reddish-brown precipitate began to appear, slowly increasing, and turning gelatinous, up to the forty-fourth day. In the latter case the odour was merely that of a mixture of acetic acid and alcohol.

The third portion had no addition made to it, and remained perfectly unchanged.

It is evident, from the above experiments, that the introduction of ferric hydrate completely upsets the equilibrium of the compound by the formation of a basic and unstable acetate; and, as the presence of potassic hydrate and carbonate in the potassic acetate produces ferric hydrate, instead of acetate, when the iron and potash solutions are mixed together in preparing tincture of ferric acetate, the effect is the formation of a basic and unstable tincture.

There appears sufficient reason to infer that the ferric hydrate produced by following the B.P. process is at first held in solution, partly by the free nitric acid, and partly by its solution in the tincture, and that by the gradual loss of nitric acid from its decomposition by the alcohol the iron is gradually deposited as one of the hydrated oxides.

This view is supported by the fact that a pint of tincture, made from solution of ferric sulphate, free from nitric acid, and potassic acetate, slightly acidified with acetic acid, has produced a tincture which, after the expiration of eighty-five days, shows no sign of decomposition whatever.

A portion of tincture which had been agitated with ferric hydrate was diluted with water, and treated with ferri- and ferro-cyanide of iron, when it behaved precisely in the same manner with those re-agents as the aqueous solution of the dried precipitate from decomposed tincture, that is, the indications obtained belonged to neither the ferrous nor ferric states, but to some other modified condition of the metal.

The rectified spirit used to displace the tincture in the percolator may be advantageously recovered by distillation where large quantities are prepared. On distilling the precipitate from a pint of the tincture ℥ij. and ♏ 80 of spirit were obtained without carrying the distillation to actual dryness.

The Dispensary, Grantham.

THE COHESION FIGURES OF OILS AS TESTS FOR THEIR IDENTITY AND PURITY.*

BY MISS KATE CRANE.

Becoming interested, from articles in the *Chemical News* of 1869, in the cohesion figures of oils as tests for their

* From the *American Journal of Pharmacy.*

identity and purity, I was led a few weeks ago to experiment with some varieties, and upon the suggestion of a friend I submit an account of some of my work to the readers of the *American Journal of Pharmacy*.

With the comparatively few trials I have made I am convinced that a little patient practice will teach the eye in a short time to detect the characteristic differences of the figures. To make these perfect it is necessary to observe the time in forming, for at *different periods* some varieties form figures very like, but with this precaution each is entirely characteristic. It is essential that the dish used, etc., be perfectly clean, so that when filled with water no dust or lint floats upon the surface, as this materially interferes with the perfect formation of the figure.

A single drop is let fall from a burette or glass rod, held steadily about four inches above the water, upon the centre of the surface.

I experimented with a number of volatile oils, by themselves, and mixed in different proportions with *oil of turpentine*.

The last-named oil, by itself, spreads instantly to the whole size of the plate, a common soup plate, and almost immediately the edge begins to break into irregular shapes, when a rapid motion takes place over the whole surface of the film, and there seems to be a contest between the cohesion of the oil particles and the adhesion between them and the water. The oil makes repeated efforts to gather itself closer together, when the water instantly reacts, giving a wavy appearance to the whole figure. The play of colours at this point is beautiful, and serves to bring out the lines more perfectly. In a few seconds innumerable little holes appear over the surface, which soon are separated only by threaded lines, and the figure is like the most exquisitely fine lace.

Oil of cinnamon forms a figure not more than half the size of the last named. In a few seconds small portions are detached, and shortly separate into distinct drops, four or five larger and a number of smaller ones, scattered about. With mixtures in different proportions of *oil of turpentine*, the figures formed differently, taking more the characteristics of the adulterant as it predominated.

Oil of nutmeg forms a large figure instantly, the edge showing a beaded line. It gathers itself together and spreads again, very like oil of turpentine, but the surface presents more the appearance of watered silk. Within 60 seconds some holes appear, and in 80 more the surface is covered with them; these scarcely spread to more than a sixteenth of an inch in diameter, but from the first each is bordered with a dotted edge. The figure lasts some time without changing materially, except the openings lengthen out into an oblong shape, remaining entirely distinct. The play of colours is very fine. With the addition of one-third the volume of *oil of turpentine*, the first spreading is little different, but openings appear in half the time, and the dotted border does not come as soon; in about four minutes the figure is most characteristically marked, and soon breaks up entirely, this being the distinctive difference between the pure oil and the mixture.

Oil of peppermint spreads instantly to a large figure, and in ten or fifteen seconds openings appear, which increase rapidly in size; at first they look somewhat like the last named, but are not nearly so numerous, and the border soon is more like tiny drops. In one and a half or two minutes they begin to run together, and the figure breaks up. With the addition of *turpentine oil* the figure forms more slowly, and the breaking up is less rapid, but in five minutes the outlines only remain.

Oil of bergamot spreads instantly; in 30 seconds tiny openings appear, not very abundant, and increase in size slowly; in five minutes they are not larger than oil of nutmeg at one and a half minutes. At first they have a dotted border, but as they increase in size this changes to a scalloped film, which spreads until, in eight or ten minutes, they are joined together over the whole surface.

This, with *turpentine oil*, gives a watered surface in spreading, much more marked and with a finer play of colours.

Experiments with fixed oils are as follows: *poppy-seed oil* spreads instantly to a large figure, retaining an entire outline, and for a few seconds the surface is unbroken, except the bare intimation of a beaded edge. In a few moments little holes appear around the edge, and soon the whole surface is broken in like manner; these increase in size very slowly. In fifteen minutes the edge begins to open, forming indentations, which gradually work their way across the figure. As they increase in length these begin to curve, and in three-quarters of an hour have doubled themselves two or three times.

Cod liver oil spreads in a large film; a little way from the edge a row of small holes appear, and in a minute or two the surface is covered with them; these gradually enlarge, assuming irregular shapes, soon separated by branching lines.

Cod liver oil with *lard oil* spreads very like the former, but in a few moments the edge opens and the film separates partly across; in a moment one of the projecting points begins to curve itself towards the centre, bending more and more until it forms a coil. Meanwhile a few holes have appeared, which spread irregularly, throwing out projecting points.

Castor oil spreads instantly, the edge remaining entire; openings appear thickly in thirty seconds, and increase gradually, but unevenly, those nearer the edge being larger, and lengthening out irregularly as they spread. The figure lasts some time. *Castor* with a little *lard oil* makes a smaller figure, and not nearly so much broken; in five minutes the holes open into each other and the figure breaks up from the edge.

A mixture of *castor* and *poppy-seed oils* spreads to form a lacework border, but smoothes out to an entire edge soon, and within a few seconds openings appear. The figure in size and general appearance is more like castor oil alone, but the holes spread less uniformly in a given time, a few being larger, but the greater portion much smaller. In fifteen minutes there is a general tendency to break up.

Castor with a little *croton oil* throws out a spray, which in a few moments unites into a thin film. The spray, as it spreads, draws out the inner portion into radiate points, which open into a beautiful network, the centre cohering closely.

Croton oil throws out, in spreading, a fine spray in advance of the more closely cohering portion, which follows quickly. The outer edge breaks up unevenly into little indentations, the border of the inside portion being quite broken, but gradually becomes nearly entire. The surface, too, has openings, which increase quite rapidly in size, the outer ones being much the larger. In the final breaking up, before the holes open one into another, the outlines are beautifully fringed.

I experimented with the varieties of *olive oil*, alone, and with mixtures of the varieties, and with the addition of other oils; but I did not get the perfectly formed figures in so short a time as Dr. Moffat mentions.* My material, probably, had either been adulterated, or was not fresh, which last, I think, would make quite a difference. However, with each variety and mixture the figure was different. If the impurities were the same that Dr. Moffat used, it appears that differences in proportion are capable of detection. Indeed, in several instances I decided that an approximate calculation of the amount of adulteration is quite satisfactorily shown by the figures formed.

Of many of the fixed oil figures I obtained very nice patterns by Dr. Moffat's method—dropping thin glazed paper upon the perfectly formed figure for an instant, then pressing between blotting paper to absorb the surplus oil; or, to bring out the pattern more clearly, floating the paper upon a coloured liquid for a moment or two before pressing.

* *Chemical News*, xviii., No. 473.

No written description can give any idea of the beauty of these figures, many of the formations being very delicately and peculiarly marked; while more beautiful than the form, and often equally characteristic, is the exquisite play of colours upon the surface.

University of Michigan, July, 1874.

RESINA PODOPHYLLI.*

BY FREDERICK B. POWER, G.P.

Eight troy ounces of powdered podophyllum were treated as per formula for Resina podophylli, U. S. P., 1870, until the alcoholic percolate ceased to cause a precipitate when dropped into water, and passed perfectly colourless; the residue contained in the percolator was dried and found to weigh seven troy ounces and two drachms, the amount of moisture in the powder having been previously ascertained and found to be 5 per cent., leaving the amount of soluble matter abstracted by the alcoholic menstruum about 4 per cent.

The precipitated resin was allowed to drain, and washed with successive portions of cold water until freed from acid, and the washings upon evaporation left no residue; the yield of resin thus obtained after careful drying was two drachms, or 3 per cent.; it was of a light yellowish brown colour, and presented a marked contrast with some of the commercial specimens examined. The percentage of resin seeming small, a larger quantity of selected rhizomes was operated upon, but the percentage in both instances was the same; the rhizomes, however, had been previously deprived of the radicles, and it being known that these are at least quite as rich in resin, the operation might have led to different results had they not been detached.

The mother liquor remaining after the precipitation of the resin, together with the washings therefrom, was concentrated by evaporation, when a portion of resinous matter separated, which was found to be entirely soluble in alcohol, being precipitated by water; but by treatment with ether was divided into two portions, soluble and insoluble, therein maintaining about the same degree of solubility as the precipitated resin. The exact amount of this substance was not ascertained, but must be at least 10 per cent. of that originally obtained by precipitation. The portion of alcoholic resin insoluble in ether thus separated by the concentration of the mother liquor, was taken in doses of five grains, producing only a slight cathartic action, attended by no unpleasant effects, while the ethereal resin taken in the same amount proved to be an active emeto-cathartic, very violent in its action, producing vomiting and purging, attended with severe griping, sense of dryness in the throat and dilatation of the pupils, the effects lasting for about twenty-four hours; the latter effect I have never seen recorded, and may possibly only be produced by an excessive dose; but it was plainly marked in this instance, affording conclusive evidence that the substance thus separated is identical with the precipitated resin, at the same time establishing the fact that *the so-called resin of podophyllum is not a true resin*, which term, as applied by the older chemists in its widest sense, distinguishes those substances insoluble in water, generally soluble in alcohol, for the most part uncrystallizable, and melting when warmed; it might with some degree of propriety be called a resinoid, from its resemblance to a resin; but this in turn is so vague in its meaning, that the nomenclature adopted by our Pharmacopœia may be more conveniently used until its true composition is more definitely determined.

The concentrated mother liquor when filtered was of a yellowish red colour, possessing a slight bitter taste and strong acid reaction; no precipitate was produced by iodohydrargyrate of potassium, tannic acid, mercuric chloride, or tincture of iodine, indicating the absence of any organic alkali; the statement of berberina having been separated from this liquid must have been applied with reference to the former officinal resin, precipitated without the agency of hydrochloric acid, as in the present process it was found to have been entirely precipitated.

The liquid, however, when quite dilute, frothed strongly upon agitation; the colour was rendered much brighter upon the addition of alkalies. Ferric chloride coloured it olive green, baryta water produced a dense precipitate, but it was not precipitated by a solution of gelatin; when mixed with an anhydrous alcohol, a perfect solution was formed, which, however, did not froth; added to an alkaline solution of cupric oxid, it became of a bluish green colour, forming upon standing a slight flocculent precipitate, which upon boiling turned to reddish brown. The liquid, when freed as much as possible of colouring matter by ether, was precipitated by barium hydrate, the precipitate collected and washed with a solution of the same, dissolved in a small portion of water and the barium removed by CO_2; the resulting solution upon evaporation possessed the peculiar odour of saponin, tending to convey the statement of Professor Mayer as to the presence of this substance, to which is no doubt partially due the extremely irritating effect upon the eyes and skin, experienced by those engaged in the manufacture of the resin on a large scale.

The residue contained in the percolator, after exhaustion by alcohol, was macerated with cold water for five days, filtered and evaporated to the consistence of an extract, possessing a sweetish odour, in colour and taste closely resembling the English extract of taraxacum. This was taken in doses of from ten to twenty grains, producing only slightly laxative but decided tonic effects. Although proving that the rhizome after exhaustion by alcohol is almost entirely destitute of cathartic properties, yet the extract thus obtained may, upon trial, merit some application.

This extract was again liquefied and treated with purified animal charcoal, which nearly deprived it of colour; the solution gave a dense precipitate upon the addition of alcohol, which, when separated, by treatment with ferric chloride and solution of borax, was found to consist principally of gum. The solutions, after the removal of the gum, contained extractive matter with some sugar; the latter, after separation by ether, was indicated by Trommer's test, and upon evaporating the solution and heating, the odour of caramel was evolved. The charcoal was then exhausted with boiling alcohol; this liquid, however, upon evaporation, left but a slight amorphous residue.

Upon the officinal resin, as previously obtained, sulphuric and hydrochloric acids produce no change of colour in the cold; nitric acid colours it deep yellowish brown; when heated with concentrated sulphuric acid it is partially dissolved, forming at first a yellowish solution, which soon changes to a deep blood red, and upon dilution with water separates flocks of a brownish-red colour. The portion undissolved by the concentrated acid is dissolved by alcohol with the formation of the same blood-red colour. The resin, when boiled with diluted sulphuric acid, is also partially dissolved, forming a red solution, though more slowly, and the filtered liquid is not capable of reducing cupric oxide in alkaline solution.

The resin fuses at 220° F., which was ascertained by placing a portion upon the surface of mercury, with a thermometer immersed in the liquid, and applying a carefully regulated heat; when heated on platinum foil it melts to a brownish liquid, and upon increasing the heat takes fire and burns with a bright sooty flame, with considerable empyreuma, leaving light porous charcoal. Two grams of the resin were boiled with a fluid ounce of water, imparting thereto a light yellow colour, while the resin ran together, forming a soft brownish mass, becoming brittle on cooling. The liquid was filtered while hot, by means of an arrangement for hot filtration; it was transparent while hot, but became turbid upon cooling, and upon evaporation of the liquid separated resinous flocks. Upon weighing the resin after this treatment it was found

* From the *American Journal of Pharmacy.*

to have lost 0·03 grams. The ethereal resin yielded similar results.

The resin is entirely soluble in amylic and methylic alcohol, acetone, and officinal solution of potassa, forming, when diluted, a bright yellow solution; it is also soluble in carbolic acid, with which it seems to combine, depositing upon evaporation reddish yellow crystals, but it is insoluble in turpentine.

Supported by a series of experiments made with the alcoholic and ethereal portion of this resin, I can confirm the statements that have been previously made, that while the portion of resin insoluble in ether is not without some activity, the ethereal resin is very much more active, and it is to be preferred for medicinal use.

By the following tabular statement the relative value of the officinal resin, as compared with some commercial varieties, will be seen based upon the relative activity of the ethereal and alcoholic resin; all were found to be free from admixture, and, with one exception, were found to be superior to many specimens of western manufacture; the difference in colour is probably due to various modifications in the process of preparation, by the application of heat in the separation of the resin, which no longer becomes necessary with the use of hydrochloric acid, or by the addition of a greater or less amount of muriate of berberina.

Some experiments were made with a view of isolating the white alkaloid, stated some time since by Professor Mayer to be contained in that portion of the former officinal resin which is insoluble in ether, but by the present process, should its hydrochlorate be soluble in water, it should have been present in the mother liquor, remaining after the precipitation of the resin, but was not there detected.

THE CARNIVOROUS HABITS OF SOME PLANTS.*

BY DR. HOOKER, C.B., D.C.L., PRES. R.S.

(*Continued from page 224.*)

To Mr. Darwin, who for some years past has had the subject under investigation, we are indebted, not merely for the complete confirmation of the facts attested by the earliest observers, but also for some additions to those facts, which are extremely important. The whole investigation still awaits publication at his hands, but some of the points which were established have been announced by Professor Asa Gray in America, to whom Mr. Darwin had communicated them.

Mr. Darwin found that the hairs of the leaf of *Drosera* responded to a piece of muscle or other animal substance, while to any particle of inorganic matter they were nearly indifferent. To minute fragments of carbonate of ammonia they were more responsive.

I will now give the results of Mrs. Treat's experiments, in her own words:—

"Fifteen minutes past ten I placed bits of raw beef on some of the most vigorous leaves of *Drosera longifolia.* Ten minutes past twelve two of the leaves had folded around the beef, hiding it from sight. Half-past eleven on the same day I placed living flies on the leaves of *D. longifolia.* At twelve o'clock and 48 minutes one of the leaves had folded entirely around its victim, and the other leaves had partially folded, and the flies had ceased to struggle. By half-past two four leaves had each folded around a fly. The leaf folds from the apex to the petiole, after the manner of its vernation. I tried mineral substance, bits of dry chalk, magnesia, and pebbles. In twenty-four hours neither the leaves nor the bristles had madeany move in clasping these articles. I wetted a piece of chalk in water, and in less than an hour the bristles were curving about it, but soon unfolded again, leaving the chalk free on the blade of the leaf."

Time will not allow me to enter into further details with respect to *Dionæa* and *Drosera.* The repeated testimony of various observers spreads over a century, and though at no time warmly received, must, I think, satisfy you that in this small family of the *Droseraceæ* we have plants which in the first place capture animals for purposes of food; and in the second digest and dissolve them by means of a fluid which is poured out for the purpose; and, thirdly, absorb the solution of animal matter which is so produced.

Before the investigations of Mr. Darwin had led other persons to work at the subject the meaning of these phenomena was very little appreciated. Only a few years ago, Duchartre, a French physiological botanist, after mentioning the views of Ellis and Curtis with respect to *Dionæa*, expressed his opinion that the idea that its leaves absorbed dissolved animal substances was too evidently in disagreement with our knowledge of the function of leaves, and the whole course of vegetable nutrition, to deserve being seriously discussed.

Perhaps if the *Droseraceæ* were an isolated case of a group of plants exhibiting propensities of this kind, there might be some reason for such a criticism. But I think I shall be able to show you that this is by no means the case. We have now reason to believe that there are many instances of these carnivorous habits in different parts of the vegetable kingdom, and among plants which have nothing else in common but this.

As another illustration I shall take the very curious group of Pitcher-plants, which is peculiar to the New World. And here also I think we shall find it most convenient to follow the historical order in the facts.

Sarracenia.—The genus *Sarracenia* consists of eight species, all similar in habit, and all natives of the eastern States of North America, where they are found more especially in bogs, and even in places covered with shallow water. Their leaves, which give them a character entirely their own, are pitcher-shaped or trumpet-like, and are collected in tufts springing immediately from the ground; and they send up at the flowering season one or more slender stems bearing each a solitary flower. This has a singular aspect, due to a great extent to the umbrella-like expansion in which the style terminates; the shape of this, or perhaps of the whole flower, caused the first English settlers to give to the plant the name of side-saddle flower.

Sarracenia purpurea is the best known species. About ten years ago it enjoyed an evanescent notoriety from the

* Address to the department of Zoology and Botany of the British Association.

fact that its rootstock was proposed as a remedy for small-pox. It is found from Newfoundland southward to Florida, and is fairly hardy under open-air cultivation in the British isles. At the commencement of the seventeenth century Clusius published a figure of it, from a sketch which found its way to Lisbon and thence to Paris. Thirty years later Johnson copied this in his edition of Gerard's Herbal, hoping "that some or other that travel into foreign parts may find this elegant plant, and know it by this small expression, and bring it home with them, so that we may come to a perfecter knowledge thereof." A few years afterwards this wish was gratified. John Tradescant, the younger. found the plant in Virginia, and succeeded in bringing it home alive to England. It was also sent to Paris from Quebec by Dr. Sarrazin, whose memory has been commemorated in the name of the genus by Tournefort.

The first fact which was observed about the pitchers was, that when they grew they contained water. But the next fact which was recorded about them was curiously mythical. Perhaps Morrison, who is responsible for it, had no favourable opportunities of studying them. for he declares them to be, what is by no means really the case, intolerant of cultivation ("respuere culturam videntur").

He speaks of the lid, which in all the species is tolerably rigidly fixed, as being furnished, by a special act of providence, with a hinge. This idea was adopted by Linnæus, and somewhat amplified by succeeding writers, who declared that in dry weather the lid closed over the mouth, and checked the loss of water by evaporation. Catesby, in his fine work on the 'Natural History of Carolina,' supposed that these water receptacles might "serve as an asylum or secure retreat for numerous insects, from frogs and other animals which feed on them;"—and others followed Linnæus in regarding the pitchers as reservoirs for birds and other animals, more especially in times of drought (præbet aquam sitientibus aviculis)."

The superficial teleology of the last century was easily satisfied, without looking far for explanations; but it is just worth while pausing for a moment to observe that, although Linnæus had no materials for making any real investigation as to the purpose of the pitchers of Sarracenias, he very sagaciously anticipated the modern views as to their affinities. They are now regarded as very near allies of water-lilies—precisely the position which Linnæus assigned to them in his fragmentary attempt at a true natural classification. And besides this he also suggested the analogy which, improbable as it may seem at first sight, has been worked out in detail by Baillon (in apparent ignorance of Linnæus' writings) between the leaves of *Sarracenia* and water-lilies.

Linnæus seems to have supposed that *Sarracenia* was originally aquatic in its habits, that it had Nymphæa-like leaves, and that when it took to a terrestrial life its leaves became hollowed out, to contain the water in which they could no longer float—in fact, he showed himself to be an evolutionist of the true Darwinian type.

Catesby's suggestion was a very infelicitous one. The insects which visit these plants may find in them a retreat, but it is one from which they never return. Linnæus' correspondent, Collinson, remarked in one of his letters, that "many poor insects lose their lives by being drowned in these cisterns of waters;" but Wiliam Bartram, the son of the botanist, seems to have been the first to have put on record, at the end of the last century, the fact that Sarracenias catch insects and put them to death, in the wholesale way that they do.

Before stopping to consider how this is actually achieved, I will carry the history a little further.

In the two species in which the mouth is unprotected by the lid it could not be doubted that a part, at any rate, of the contained fluid was supplied by rain. But in *Sarracenia variolaris*, in which the lid closes over the mouth, so that rain cannot readily enter it, there is no doubt that a fluid is secreted at the bottom of the pitchers, which probably has a digestive function. William Bartram, in the preface to his travels in 1791, described this fluid, but he was mistaken in supposing that it acted as a lure. There is a sugary secretion which attracts insects, but this is only found at the upper part of the tube. Bartram must be credited with the suggestion, which he, however, only put forward doubtfully, that the insects were dissolved in the fluid, and then became available for the alimentation of the plants.

Sir J. E. Smith, who published a figure and description of *Sarracenia variolaris*, noticed that it secreted fluid, but was content to suppose that it was merely the gaseous products of the decomposition of insects that subserved the processes of vegetation. In 1829, however, thirty years after Bartram's book, Burnett wrote a paper containing a good many original ideas, expressed in a somewhat quaint fashion, in which he very strongly insisted on the existence of a true digestive process in the case of *Sarracenia*, analogous to that which takes place in the stomach of an animal.

Our knowledge of the habits of *Sarracenia variolaris* is now pretty complete, owing to the observations of two South Carolina physicians. One, Dr. M'Bride, made his observations half a century ago, but they had, till quite recently, completely fallen into oblivion. He devoted himself to the task of ascertaining why it was that *Sarracenia variolaris* was visited by flies, and how it was that it captured them. This is what he ascertained:—

"The cause which attracts flies is evidently a viscid substance resembling honey, secreted by or exuding from the internal surface of the tube. From the margin, where it commences, it does not extend lower than one-fourth of an inch. The falling of the insect, as soon as it enters the tube, is wholly attributable to the downward or inverted position of the hairs of the internal surface of the leaf. At the bottom of a tube split open the hairs are plainly discernible. pointing downwards; as the eye ranges upward they gradually become shorter and attenuated, till at or just below the surface covered by the bait they are no longer perceptible to the naked eye, nor to the most delicate touch. It is here that the fly cannot take a hold sufficiently strong to support itself, but falls."

Dr. Mellichamp, who is now resident in the district in which Dr. M'Bride made his observations, has added a good many particulars to our knowledge. He first investigated the fluid which is secreted at the bottom of the tubes. He satisfied himself that it was really secreted, and describes it as mucilaginous, but leaving in the mouth a peculiar astringency. He compared the action of this fluid with that of distilled water on pieces of fresh venison, and found that after fifteen hours the fluid had produced most change, and also most smell; he therefore concluded that as the leaves, when stuffed with insects, become most disgusting in odour, we have to do, not with a true digestion but with an accelerated decomposition. Although he did not attribute any true digestive power to the fluid secreted by the pitchers, he found that it had a remarkable anæsthetic effect upon flies immersed in it. He remarked that "a fly when thrown into water is very apt to escape, as the fluid seems to *run* from its wings," but it never escaped from the *Sarracenia* secretion. About half a minute after being thrown in, the fly became to all appearance dead, though, if removed, it gradually recovered in from half an hour to an hour.

According to Dr. Mellichamp, the sugary lure discovered by Dr. M'Bride at the mouth of the pitchers is not found on either the young ones of one season nor the older ones of the previous year. He found, however, that about May it could be detected without difficulty, and, more wonderful still, that there is a honey-baited pathway leading directly from the ground to the mouth, along the broad wing of the pitcher, up which insects are led to their destruction.

From these narratives it is evident that there are two very different types of pitcher in *Sarracenia*, and an examination of the species shows that there must probably be three. These may be primarily classified into those with the mouth open and lid erect, and which consequently receive the rain water in more or less abundance, and those with the mouth closed by the lid, into which rain can hardly, if at all, find ingress.

To the first of these belongs the well-known *S. purpurea*, with inclined pitchers, and a lid so disposed as to direct all the rain that falls upon it also into the pitcher; also *S. flava*, *rubra*, and *Drummondii*, all with erect pitchers and vertical lids; of these three the lid in a young state arches over the mouth, and in an old state stands nearly erect, and has the sides so reflected that the rain which falls on its upper surface is guided down the outside of the back of the pitcher, as if to prevent the flooding of the latter.

To the second group belong *S. psittacina* and *S. variolaris*.

The tissues of the internal surfaces of the pitchers are singularly beautiful. They have been described in one species only, the *S. purpurea*, by August Vogt; but from this all the other species which I have examined differ materially. Beginning from the upper part of the pitcher, there are four surfaces, characterized by different tissues, which I shall name and define as follows:—

1. An *attractive* surface, occupying the inner surface of the lid, which is covered with an epidermis, stomata, and (in common with the mouth of the pitcher) with minute honey-secreting glands; it is further often more highly coloured than any other part of the pitcher, in order to attract insects to the honey.

2. A *conducting* surface, which is opaque, formed of glassy cells, which are produced into deflexed, short, conical, spinous processes. These processes, overlapping like the tiles of a house, form a surface down which an insect slips, and affords no foothold to an insect attempting to crawl up again.

3. A *glandular* surface (seen in *S. purpurea*), which occupies a considerable portion of the cavity of the pitcher below the conducting surface. It is formed of a layer of epidermis with sinuous cells, and is studded with glands; and being smooth and polished, this too affords no foothold for escaping insects.

4. A *detentive* surface, which occupies the lower part of the pitcher, in some cases for nearly its whole length. It possesses no cuticle, and is studded with deflexed, rigid, glass-like, needle-formed, striated hairs, which further conveys towards the axis of the diminishing cavity, so that an insect, if once amongst them, is effectually detained, and its struggles have no other result than to wedge it lower and more firmly in the pitcher.

Now, it is a very curious thing that in *S. purpurea*, which has an open pitcher, so formed as to receive and retain a maximum of rain, no honey secretion has hitherto been found, nor has any water been seen to be secreted in the pitcher; it is further the only species in which (as stated above) I have found a special glandular surface, and in which no glands occur on the detentive surface. This concurrence of circumstances suggests the possibility of this plant either having no proper secreting of its own, or only giving it off after the pitcher has been filled with rain water.

In *S. flava*, which has open-mouthed pitchers and no special glandular surface, I find glands in the upper portion of the detentive surface, amongst the hairs, but not in the middle or lower part of the same surface. It is proved that *S. flava* secretes fluid, but under what precise conditions I am not aware. I have found none but what may have been accidentally introduced in the few cultivated specimens which I have examined, either in the full-grown state or in the half-grown, when the lid arches over the pitcher. I find the honey in these as described by the American observers, and honey secreting glands on the edge of the wing of the pitcher, together with similar glands on the outer surface of the pitcher, as seen by Vogt in *S. purpurea*.

Of the pitchers with closed mouths, I have examined those of *S. variolaris* only, whose tissues closely resemble those of *S. flava*. That it secretes a fluid noxious to insects there is no doubt, though in the specimens I examined I found none.

There is obviously thus much still to be learned with regard to *Sarracenia*, and I hope that American botanists will apply themselves to this task. It is not probable that three pitchers so differently constructed as those of *S. flava*, *purpurea*, and *variolaris*, and presenting such differences in their tissues, should act similarly. The fact that insects normally decompose in the fluid of all, would suggest the probability that they all feed on the products of decomposition; but as yet we are absolutely ignorant whether the glands within the pitchers are secretive or absorptive, or both; if secretive, whether they secrete water or a solvent; and if absorptive, whether they absorb animal matter or the products of decomposition.

It is quite likely that, just as the saccharine exudation only makes its appearance during one particular period in the life of the pitcher, so the digestive functions may also be only of short duration. We should be prepared for this from the case of the *Dionæa*, the leaves of which cease after a time to be fit for absorption, and become less sensitive. It is quite certain that the insects which go on accumulating in the pitchers of *Sarracenias* must be far in excess of its needs for any legitimate process of digestion. They decompose; and various insects, too wary to be entrapped themselves, seem habitually to drop their eggs into the open mouth of the pitchers, to take advantage of the accumulation of food. The old pitchers are consequently found to contain living larvæ and maggots, a sufficient proof that the original properties of the fluid which they secreted must have become exhausted; and Barton tells us that various insectivorous birds slit open the pitchers with their beaks to get at the contents. This was probably the origin of Linnæus' statement that the pitchers supplied birds with water.

The pitchers finally decay, and part, at any rate, of their contents must supply some nutriment to the plant by fertilizing the ground in which it grows.

Darlingtonia.—I cannot take leave of *Sarracenia* without a short notice of its near ally, *Darlingtonia*, a still more wonderful plant, an outlier of *Sarracenia* in geographical distribution, being found at an elevation of 5,000 feet on the Sierra Nevada of California, far west of any locality inhabited by *Sarracenia*. It has pitchers of two forms; one, peculiar to the infant state of the plant, consists of narrow, somewhat twisted, trumpet-shaped tubes, with very oblique open mouths, the dorsal lip of which is drawn out into a long, slender, arching, scarlet hood, that hardly closes the mouth. The slight twist in the tube causes these mouths to point in various directions, and they entrap very small insects only. Before arriving at a state of maturity the plant bears much larger, suberect pitchers, also twisted, with the lip produced into a large inflated hood, that completely arches over a very small entrance to the cavity of the pitcher. A singular orange-red, flabby, two-lobed organ hangs from the end of the hood, right in front of the entrance, which, as I was informed last week by letter from Professor Asa Gray, is smeared with honey on its inner surface. These pitchers are crammed with large insects, especially moths, which decompose in them, and result in a putrid mass. I have no information of water being found in its pitchers in its native country, but have myself found a slight acid secretion in the young states of both forms of pitcher.

The tissues of the inner surfaces of the pitchers of both the young and old plant I find to be very similar to those of *Sarracenia variolaris* and *flava*.

Looking at a flowering specimen of *Darlingtonia*, I was struck with a remarkable analogy between the arrangement and colouring of the parts of the leaf and of the flower. The petals are of the same colour as the flap of the pitcher, and between each pair of petals is a hole (formed by a notch in the opposed margins of each) leading to the stamens and stigma. Turning to the pitcher, the relation of its flap to its entrance is somewhat similar. Now, we know that coloured petals are specially attractive organs, and that the object of their colour is to bring insects to feed on the pollen or nectar, and in this case, by means of the hole, to fertilize the flower; and that the object of the flap and its sugar is also to attract insects, but with a very different result, cannot be doubted. It is hence conceivable that this marvellous plant lures insects to its flowers for one object, and feeds them while it uses them to fertilize itself, and that, this accomplished, some of its benefactors are thereafter lured to its pitchers for the sake of feeding itself!

(*To be continued.*)

HERB-POISONING AT THE CAPE OF GOOD HOPE.*

BY GEORGE GREY, M.D., F.G.S. EDIN.,

District Surgeon to the Government for the Division of Cradock, Cape of Good Hope.

The Bushmen tribes (Bosjesmen) of Southern Africa are pretty generally known to be naturally cunning, treacherous, and vindictive. As regards *physique*, authorities in ethnological science have placed them in all but the lowest grade in the human scale, and their mental capacity is, no doubt, only on a par with their physical configuration. Nevertheless, these people manifest certain inherent powers of perception, and they may safely be credited with a tolerably accurate knowledge as to right and wrong. We must, therefore, not view them, as some have been disposed to do, in the light of beings wholly devoid of a moral sense—ill-regulated and distorted though it undoubtedly is.

Consequently the Bushman of Southern Africa must, like his superiors in the human family, be held responsible for his deeds, whether good or bad; though, after taking into consideration his very depraved habits and miserable mode of living, his criminal propensities, and his disregard of all means calculated to raise him from his degraded condition, we feel compelled to relegate him, in a social sense, to the class commonly denominated "evil-doers."

But in the Kaffir race, of which people we have a considerable number scattered throughout the district of Cradock, comprising principally individuals belonging to the Amaxosa, Tambookie, and Basuto tribes, we find no trace of resemblance to the genuine aborigines of Southern Africa. The Kaffir, whose original habitat is believed to be North-East Africa, is almost as distinct and different in his physical and mental development from the Bushman as he is from the European; and, if placed in comparison with the Koranna and Damara Hottentots, the Griquas, Bosjesmen, and other unpromising people peculiar to this region, we have to pronounce him in every respect a superior variety of the genus *Homo*.

But, notwithstanding, the Kaffir is an utter savage, and it is with much difficulty he can be brought to a proper appreciation of European laws and customs; a considerable time must elapse before the march of civilisation here, progressive as it is, can render him a trustworthy dependent to the colonists; and therefore we have good ground for assuming that, until such can take place, our barbarous coloured races are not likely to refrain from resorting, as occasion may suit them, to the crime of secret poisoning. We must not, however, forget that it is a stated axiom in the ethics and laws of savage races, that though criminal acts, or such as relate to death by poisoning, and, indeed, all serious offences, when perpetrated against any members of their own tribe or nation, are followed by condign punishment on the offenders, such crimes are really considered as meritorious deeds when members of foreign, and, therefore, to them ill-favoured, communities are the victims.

As bearing upon the foregoing remarks, I would now observe, that during the last eight years I have been required to investigate, in my official capacity as district surgeon of this division, eleven cases of reported poisoning in and around Cradock. In many of these whole families have been affected, and generally in each family one and sometimes more deaths have occurred. The above may be looked upon as a considerable number for a comparatively small and scattered population, which includes, in town and country, according to the last census, only 12,228 inhabitants, the whole district embracing an area of 1,806,692 acres (2,986 square miles). We must also take into account that, perhaps, not more than one-half of the above crimes (at least among the coloured people), when committed in isolated places, are ever brought to light.

It is not my intention to enter at present into any detailed statement on the cases above referred to, except on one which recently occurred at Middelburg, and which involved very serious and important issues. I would only remark, with respect to the others, that in many of them I found that strychnia, or else the seeds of *Strychnos Nux-vomica*, had been the drug resorted to; and in other cases the tuberous roots of certain iridaceous plants had, as far as could be ascertained, been used. At the scattered farm-houses hereabouts a small supply of strychnia is usually kept for the destruction of leopards, wolves, jackals, wild dogs, and other troublesome carnivora; this poison is, therefore, through carelessness, often of easy access to persons who may be criminally disposed.

In fatal cases of poisoning by strychnia, that alkaloid is not now considered a very difficult substance to detect; but, in this colony, which possesses a large and widely extended flora, an arrival at a correct determination by analysis as to the nature and properties of any indigenous plants used in attempts to poison cannot fail, in the absence of other good proof, to be a very complicated and troublesome procedure. Therefore, when a case of such a character rests otherwise upon very doubtful evidence, who can be surprised that a satisfactory conclusion is not frequently attained?

On March 25th, last year, an express reached Cradock from Mr. C. W. Andrews, resident magistrate of Middleburg—a town sixty miles north of this—with a request that I would attend there at once, for the purpose of rendering professional aid to the survivors in a case of poisoning which had just occurred. The whole household of Dr. Coward, district surgeon for Middelburg (except a Bushman maid-servant), had been seized on the previous day, after partaking of some soup, with alarming vomiting, followed by a painful feeling of constriction across the chest, and other abnormal symptoms. Mr. J. O. Reeve, a merchant of Graaff Reinet, at the time on a visit to Dr. Coward, had died within eighteen hours of receipt of the poison, and, on the same day (24th), little hope was entertained of the recovery of the others. On my arrival at Middelburg, I found the whole family overwhelmed with grief; for, on the morning of the 25th, a fine little boy of Dr. Coward's, eight years of age, had also succumbed to the effects of the poison. In all, eight persons had been affected by it. Fortunately, by that time serious symptoms in the survivors had considerably abated, and although all were suffering from severe shock and after-effects, restoration was being gradually established. I made a *post-mortem* examination on the body of Mr. Reeve, who had been a well-formed and muscular man of about 30 years. The body presented, externally, a natural appearance. There was no *rigor mortis*—a characteristic feature in cases of death from *Strychnos*, *Brehmia*, *Hyænanche*, *Melianthus* (the three last named are indigenous to the colony), and other substances belonging to the class "neurotic poisons." The lungs and heart were healthy, but the pulmonary arteries and their branches were engorged with a remarkably dark, venous blood. The right ventricle of the heart was filled with a similar very dark blood. The muscular structure of the heart was very flaccid. The stomach, where I had thought to have discovered indica-

* Reprinted from the *British Medical Journal*.

tions of inflammatory action, was quite empty, and exhibited no signs of inflammation. The continued vomiting, which had lasted for several hours after taking the soup, had evidently caused a rejection of the poison, and death had resulted from secondary causes. Other organs were natural in appearance, except that there was venous congestion throughout, and especially in the blood-vessels of the brain.

There can be no doubt that death resulted from effects produced by the soup taken on March 23rd, and, from the symptoms as observed till death in the two fatal cases, viz., intense vomiting, a constant feeling of oppression over the chest, a feeble and intermitting action of the heart, a tendency to coma for some hours before death, and from *post mortem* appearances I am of opinion that the poison used belonged to the class termed by Orfila "narcotico-irritant."

I think that the effects (secondary) of the poison were probably partial paralysis of the coats of blood-vessels, muscles, and nerves, belonging to the organs of respiration, involving considerably the cardiac and coronary plexuses. This would result in more or less loss of motor power, and may account (in part at least) for the flaccid condition of the walls of the heart, for the laboured respiration, and consequently imperfect oxidation of the blood.

The circumstances connected with the administration of the poison may be thus briefly recounted.

On March 20th, Dr. Coward returned to Middelburg after an absence of two or three weeks. He had been joined *en route* by Mr. Reeve, at Graaff Reinet. In the meantime, the Bushgirl had been employed as a servant at the house in Middelburg. Taking advantage of her master's absence, she had grossly misconducted herself, having, among other misdeeds, been in the habit of admitting a Kaffir admirer to the house, and, to disguise the fact, stated that the house was haunted. This being detected, she was very properly reprimanded. She then expressed to Miss Coward her intention of being revenged. On the evening of the 22nd, after eating some curry, some of the family party experienced a feeling of nausea, but this did not excite much notice. On the next day, soup was served up at dinner hour, and, before many spoonfuls had been taken, Mr. Reeve first, and afterwards every person in the house, except the suspected individual, was attacked with the alarming symptoms to which I have referred. Dr. Coward, though suffering severely himself, acted most promptly and energetically, and without doubt six out of the eight persons attacked owe their lives to his exertions. Dr. Coward suggested the possibility of the girl having got access to tartar emetic in his surgery. After charring with strong sulphuric acid to destroy all organic matter, I applied to scrapings from the stomach, and to part of the soup, the proper tests for detection of antimony, but with a negative result.

The belief at present is, that certain poisonous herbs (recent) had been resorted to, and that these had been furnished to the Bushgirl by her ally the Kaffir. An extractive of the material could readily be added to any article of diet, and this would appear to have been done, first in a small quantity to the curry on March 22nd, and again in much larger quantity on March 23rd.

I will now, if space permit, add a few words on some of the native plants, and their properties, which may have been used as agents in the case in question, concluding by a short statement of experiments on their action compared with some on that of the poisoned soup, as affecting animals.

By order of the resident magistrate, the tent of the Kaffir prisoner was searched, and a great number of dried roots and stems of native plants, besides seeds (some not indigenous), powdered wood, charcoal, wings and legs of the red locusts, hair of the Klipspringer (*Oreotragus saltatrix*), and other substances used by Kaffir impostors and witch doctors, were found in a large bag and removed. Owing to the dry and fragmentary state of these articles, it was almost impossible to identify many of them; but most proved, on testing, to be comparatively innocuous, and at present opinion is against the probability of any of them having been used prejudicially in the case in question. Among the seeds in the parcel, I found about half a dozen belonging to *Strychnos nuxvomica*—a quantity which would suffice to kill at least twenty persons; but the absence of symptoms characteristic of poisoning by nux vomica dismisses the admission of these seeds into the case. *Strychnos Nux-vomica* is an Indian plant, but we have one allied to it in *Hyænanche globosa* of the western districts, and also in *Brehmia spinosa* of Kaffirland and Natal. The latter plant is also a native of Madagascar. Among other recognizable plant-specimens were *Pilogyne Ecklonii*, termed in vernacular *Davidjes wortel*, a cucurbitaceous shrub, emetic, cathartic, and diuretic; *Garullum bipinnatum* (Compositæ) called "slangwortel," Anglicè, "snake-root," from its reputed efficacy in snake-bites; pieces of the stems of the *Gomphocarpus*, one of the varieties of the "Melk Bosjes," peculiar to the Cape, an Asclepiad (the white, milk-like juice of this plant is very acrid and corrosive); the *Cadaba juncea*, or "zwart-storm" of the colonists (*Capparidaceæ*), non-poisonous; the seeds of *Plantago major*, "plantain" (*H. Bolus*), comparatively harmless; and the resinous secretion from the urinary bladder of the *Hyrax capensis*, the "klipdas" or "rock-rabbit," used only as a stimulant and antispasmodic.

The following indigenous plants, mostly virulent poisons, have come under observation, in the course of the inquiry, as possible agents in the case, and are, I think, worthy of record.

Lessertia annularis, "T'Nenta" of the Karroo, produces cerebro-spinal paralysis and death in sheep and goats, like the *Gastrolobium*, the evil-renowned "poison-pea" of Australia.

Melianthus major (Melianthеæ), called locally *Truijtje roer mij niet*, Angl., "Gertrude, disturb me not," is a large, shrubby, disagreeably scented plant, occurring in patches in various parts of the Eastern Province. It has a widely creeping root. The leaves are alternate, smooth, pinnate, glauceous beneath; the flowers brown-red, an inch long, capsule four-celled, seeds two in each cell, black and shining. A decoction of the leaves is used as an antiseptic for sore-throat and various forms of ulcers. The bark of the root and stem are very poisonous. I will refer further on to some of its properties. There are four known species of this plant—*Melianthus major*; *M. comosus*; *M. minor*; *M. dregeana.*

Toxicophlœa (Apocyneæ), the "gift-boon," or "poison-tree" of the colonists, is a small tree or large shrub, with dark, dotted, and virulently poisonous bark. The flowers are sweetly scented, like jessamine, in dense, axillary, many-flowered fasicles. The only species at present known is, I believe, the *T. Thunbergii.* It produces the notorious arrow-poison of the Bosjesmen. Thunberg states "the aborigines use a decoction of the bark, reduced to the consistence of jelly, for poisoning their arrows." The symptoms in a case of accidental poisoning at Grahamstown by a decoction of the bark were rigors without convulsions, loss of muscular power, and death in a very few minutes. *Toxicophlœa* grows in the south-eastern parts of the colony and at Natal. Some knowledge of the nature and properties of this curious South African plant may be, to some extent, interesting in an ethnological point of view; for, now that the ever-advancing footsteps of the white man are exercising so dispersing an effect on the old strongholds, as well as on the old-established customs of the aborigines, the use of the deadly little missiles of the Bushman is gradually lessening, and before the lapse of many years may probably have to be numbered among the things of the past. Dr. Hooker will, I feel confident, be glad to give further information relating to this plant to any inquirers interested. I understand some specimens of it are thriving under his fostering care at the Royal Botanic Gardens, Kew.

Ornithogalum altissimum (Asphodeleæ), termed locally, "Magerman," is a large bulbous plant, bearing a tall solitary scape, which speedily withers. The flowers are white and whitish-yellow. The bulb is used occasionally as a diuretic and sedative. I introduce a note on this plant, because some experienced persons have stated that its active principle is in a great degree poisonous. But this is certainly not confirmed by my own experience. Professor Mac Owan, of Somerset, and Mr. H. Bolus, of Graaff Reinet, (two able observers) also believe it to be almost inert.

But, perhaps, the most important of the genera of our suspected herbs now deserves notice. I refer to *Moræa* (Thunberg) *Homeria* (sweet), called in Cape vernacular, "wilde tulp." It belongs to the family *Iridæa.* The root is a corm or tuberous bulb, covered with a fibrous, reticulated, hardened coat; shaft erect, smooth; branches 2-3-flowered (Pappe). The leaves are mostly few and narrow. The flowers yellow, white, orange, or parti-coloured pedicillate, rising from crowded or subsolitary terminal sheaths (Harvey, who states that the species are numerous). This plant is to be found in various parts of the colony, and the species vary apparently in different localities. They grow plentifully throughout the Karroo, and appear to thrive in arid plains and sterile, rocky spots. We may frequently notice their pretty vari-coloured flowers where little else of vegetative growth is to be seen—in dolorous-looking places, almost suggestive to the fancy of Ebenezer Elliott's

"Grim region in a world of woe,
Where toil-sown wheat and paupers will not grow."

The variety best known for its poisonous properties is the *M. collina*, native in the Western Province, and is the only species yet described growing there.* The late Dr. Pappe states that, "judging from the rapidity with which death ensued in recent cases when some of these bulbs had been eaten by mistake, they must be of a very poisonous kind." The only deaths resulting from these plants (except in a considerable number of cases in cattle) hitherto recorded have been caused by eating accidentally the bulbous parts of the *M. collina*; and a comparison of the symptoms in these cases with those in the fatal cases at Middleburg gives in some respects a slightly different result; for example, in the several persons in whom *M. collina* had been the fatal agent, acute gastritis and also enteritis occurred, notwithstanding that repeated vomiting had cleared the stomach, as in the persons affected at Middelburg. Consequently, in the former instances, the mucous membrane of the stomach and small intestines were found to be highly vascular and inflamed. Such was absent in the cases at Middelburg, though other *post mortem* appearances corresponded. To the present time, the only species of *Moræa* belonging to the Eastern Province which has been described is *M. polyanthus* (Thunberg) the "tulp blommetje." It is very probable that the effects of the "tulp" of the eastern districts differ from the western in degree only, and that the one is equally, or nearly equally, poisonous with the other. Portions of dry husks and stems of about a dozen specimens of *Moræa* were found in a room of Dr. Coward's house, previously occupied by the suspected Bushgirl, and these were forwarded to me for further report. The fleshy parts of the rootstocks being absent would appear in itself to afford extra presumptive proof against the girl; for, doubtless, the active part of the herbs had been disposed of for some nefarious purpose.

Soon after the occurrence, I prepared, as opportunity offered, concentrated decoctions and extracts from portions of all substances procurable to which I have referred, and applied to these various chemical tests and reagents, comparing the results of these with others applied to extractives prepared from the poisoned soup. These I have duly recorded, and may give a detailed statement upon them on a future occasion.

Mr. Gibb, Government Analyst at Cape Town, to whom I referred for a report on the nature of the poisoned soup, states that he finds it to contain "a peculiar vegetable principle similar to veratria, and highly poisonous;" and that "he believes it to be derived from a species of *Moræa*, or 'tulp.'" The latter is, I venture to think, the prevailing opinion, and the impression is, that one or more of the eastern district species formed the deadly element in the case at Middelburg.

It may be sufficient that I conclude this paper by giving a brief summary of the effects on animals after administration of (1) the soup, and (2) preparations made from some of the more important of the plant-substances to which I have adverted. On March 29th, I gave six ounces of the soup to a full-grown dog. It was taken voluntarily and with avidity. Rigors set in within three or four minutes, and soon afterwards intense vomiting, which continued at short intervals for about twenty minutes, and then ceased. There were no convulsions. The dog recovered, but refused to touch the soup again, although kept to a room without other food or water for six days. On April 3rd, a teaspoonful was administered to a kitten; rigors occurred, but no vomiting. It died within three hours. At the same time, a teaspoonful was given to a pup a month old. *Very slight* vomiting, with rigors, commenced in a few minutes, and continued for nearly two hours, the animal dying within six hours. No convulsions or rigor mortis either in this case or that of the kitten.

April 23rd. I concentrated a portion of the soup, so as to form an extract, and gave a few drops to a kitten. This animal was first of all convulsed, then partly paralysed, and died within eight minutes.

April 25th. A teaspoonful of decoctum melianthi ("Truijtje roer mij niet") was given to a kitten. Frothing at the mouth and shivering followed, but nothing more serious for twenty-four hours. About a dessert-spoonful was then administered. The animal was then attacked with convulsive movements, staggered gait, and general loss of muscular control. It died in less than two minutes. Considerable rigor mortis ensued. A *post-mortem* examination revealed considerable venous congestion throughout, and an inflamed condition of both pericardium and endocardium. The poison had evidently acted also through the brain and spinal cord, thus causing tetanic rigidity. The bark of *Melianthus* is, therefore, no doubt, a powerful neurotic poison, but it could not have been the material used in the poisonings at Middelburg.

A decoction of some rootstocks of one species of *Moræa* (boiled for four hours) was given to a dog twice within six hours, in doses of a teaspoonful. Nothing very serious supervened on the first dose, but the second proved fatal in a little more than two hours; symptoms being vomiting, rigors, heaving of chest and flanks, and speedy collapse. The mucous membrane of the stomach was slightly congested, and a general venous engorgement existed, affecting especially the right side of the heart and corresponding pulmonary blood-vessels. Otherwise nothing abnormal could be distinguished.

On July 3rd, Dr. Coward forwarded me a small parcel containing corms belonging to another Eastern Province variety of *Moræa.* Experiments with these specimens afforded results nearly identical with those above mentioned, the very poisonous properties of this order of plants being thereby confirmed.

Alas for the glorious uncertainty of the law! The Solicitor-General has decided that the evidence in the case is nearly wholly circumstantial, and that both prisoners must be discharged on their own recognizances. But murder by poison is nearly always a secret crime, and I should have thought that the evidence in this case was sufficiently strong to warrant the bringing in of a true bill. In this country, where colonists are so largely dependent upon the coloured population for servants' work, it is not too much to say that whole families of innocent persons run a risk at all times of being poisoned for no other reason than that the malice of certain ill-grained and very troublesome "coloured brethren" may be indulged.

* It may be seen at the Botanic Gardens, Kew.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 26, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW EXAMINATIONS.

ONE of the wisest things, as certainly it is the kindest, that have been officially devised is the amended form for conducting our examinations. An examination in itself has definite limits: it can neither bestow nor create knowledge, but it can stimulate its acquirement and indicate its right direction. If not perfect in its results, it is yet the best and practically the only test we can employ in determining the standard of qualification.

Bearing this truth in mind, the Board of Examiners has deliberately set about the task, how to retain the official character of the ordeal, and, at the same time, to render it an efficient aid towards the well-being and advancement of the future pharmacist; in other words, to make it the interest of every candidate to submit to its requirements, were no honorary distinction granted as an additional motive. That in this they have succeeded little doubt can be entertained. Still, though the general bearing of the subject has been discussed already, a further debt of explanation is due to two classes, both of whose opinions are entitled to respect. On the one hand, masters see in these new provisions a chance of a material diminution in the ranks of their assistants, who may fear to enter on a course too well kept and guarded, or who may consider that the promised gain is by no means an equivalent for the struggle. On the other, assistants see nothng in perspective but an ever-increasing stringency, which they loudly deprecate, and the justice of which they are stoutly inclined to doubt.

We accept these questionings as a healthy sign that neither employers nor employed treat educational arrangements with indifference; we would talk the matter over, and shall fail ignominiously in our intention, could we not show that it is the misconception respecting the word *stringent* that has unhappily complicated the discussion. Carefully perusing the printed document relating to the regulations soon to come into force, we arrive at this conclusion, that the precise information is here made legally imperative, which the experience of every modern pharmacist would recognize as being the most direct and most effectual means for the attainment of that success with which he has himself been favoured. We speak now solely with regard to trade position and emolument, leaving intellectual considerations and social standing outside the present argument. Further, that the precise information here made legally imperative is that of which successful masters have felt themselves specially in want; which sometimes they have acquired with difficulty in after years; and, failing which, it has required their utmost skill and perseverance to prosper in their undertakings. A man is not stringent who requires his apprentice to know his business; he is not hard nor tyrannical in his dealings who insists that those entrusted to his care should be competent to discharge their duties. That is the official attitude assumed by the Pharmaceutical Society, and both master and student should rejoice that the reign of mere book literature should have ended, and that that of practical knowledge and common sense had been inaugurated.

Little need be said of the Preliminary Examination, which it is to be hoped will speedily be withdrawn from our supervision, and relegated to its appropriate sphere. It is not for pharmacists (actively engaged in peculiar occupations) to decide upon points of Latin grammar which probably they may have forgotten, or to sit in judgment on the rules of English composition, which are constantly subject to variation and to fresh theories of explanation. Nor should the candidate be expected to translate one line from the 'Selecta è Præscriptis,' for that is an evidence that he has stood behind a druggist's counter, not that his previous classical scholarship has fitted him for that occupation. Nevertheless, this very examination, as it now stands, displays the strong bias of the Examiners in the direction of common sense. Centres for conducting the Preliminary Examination have been established, and after December 31st next, medical Latin will be abandoned. That the elementary rules of arithmetic are essential, as well as a thorough knowledge of the British and metrical systems of weights and measures, is a sentiment that will pass unchallenged.

With fewer words the Major Examination may be despatched: it is not compulsory; it is an affair of honour; it confers a title, and exempts its fortunate possessor from serving with eleven other honest men upon a jury. As to what may be the exact nature of its requirements, pharmacists are disposed to raise few objections, and by consent they leave its stipulations to be carefully considered by the directing body. But this Minor Examination is the disturbance and the cause of war: the vexed question, and a fertile theme for grievance. The best mode (such is our sincere belief) of quieting preconceived anxieties is to read at leisure the text of its instructions.

Candidates are required to read prescriptions, detect unusual doses, and write accurate and appropriate directions. The Board is not to be harshly censured for the stringency of this enactment: it is a plagiarism from many a brass plate and circular, whereon we read in conspicuous letters, "Prescriptions accurately dispensed." That in an examination these should be required to be given without abbreviation, is simply a test of correct Latinity; and whereas some are wonderfully deficient in the power of deciphering an autograph, ordinary prescriptions written in the mother tongue are to be rendered in good Latin. We need not argue the point that a man engaged in Pharmacy, and unable to read a physician's recipe, is more qualified to pass the Insolvent Debtors' than any arrangement of a Minor Examination.

The subjects of Practical Dispensing, Pharmacy, and Materia Medica may be handed over to the meditation of the most apprehensive. Let him consider the case in his more quiet moments, carefully, slowly, and dispassionately, and let him answer to himself these questions: "Could an examining body have asked less? Are they asking for the wrong things? Are they seeking to catch me with their guile, or setting traps or placing stumbling blocks before the unwary?"

Surely the whole balance of evidence is a refutation of such suppositions. In dispensing, the candidate is to weigh, measure, and compound, direct and finish; in pharmacy, he is to show practical knowledge; and in materia medica, he is to do the same. In botany, the practical element is no less in the ascendant.

Every road, says the old proverb, *leads to Rome*, and likewise every pharmaceutical examination, however varied in its construction, must hinge on chemistry. No branch of inquiry so severely taxes the skill of the Examiner. It rests with him to ascertain how far the candidate is cleverly retailing information gleaned with a special object, or how far he is really conversant with a science on which his future must depend.

Herein consists the whole stringency to which allusion has been made so often. That a student should recognize the ordinary chemicals that are used in medicine requires no special application; but he must further know the processes by which they are produced, their composition, and the decompositions that are involved in chemical experiment. In addition, he must show the possession of an acquaintance with the laws of chemical philosophy, and be able to give practical demonstration of the means employed in reference to specific gravities, densities, and temperatures. No carefully stored recollections from printed manuals; no surreptitious notes, no ingeniously prepared answers to anticipated queries, will suffice, any more than they will enable him to determine practically by means of tests, the presence in solution of the chemicals in common use, or to explain the reactions which may possibly occur.

One thing will prove sufficient, which will inspire him with confidence in himself for ever, and lead him to meet his examination with a smile: that is, a course of honourable, sustained preparation. Books must by no means be neglected, for they save infinite and useless labour; they are the result, as well as the compendiums, of trained thought and painfully worked-out experiment. Teachers are to be held in honour, for they explain, instruct, and guide. But there is a point at which books and teachers must resign their office, and nothing will stand in the stead of personal practical work. Then seeming difficulties will disappear; and never let it be forgotten that a successful examination is just so far useful as it has prepared the competitor for those active duties on which he is about to enter.

How, then, shall a man study chemistry? Let him bend his own glass tubes, make his own thermometer, and fit up his own apparatus; let him prepare his own tests, trust to his own observations, work out his own equations, and write his own diagrams. Let him take authorized standard manuals, and himself determine their correctness, and in so doing understand the reason of their suggestions. In this manner every chemist known to fame has been created; and this is the manufacturing process adopted by every independent scholar. The Board of Examiners knew well that this frame of mind is not to be expected from the average race of students, though it is the direct tendency of their regulations to foster this excellent spirit. But they are justified in their action by the presence of many admirable schools. London and the country both can boast of institutions where the highest class of practical education is afforded. Standing as we are at the very threshold of a new session, we would urge our young pharmacists to avail themselves of these advantages; and should they do so conscientiously and courageously, they will be the first most heartily to endorse our opening statement: one of the wisest things, as certainly it is the kindest, that have been officially devised, is the amended form for conducting our examinations.

AMERICAN PHARMACEUTICAL ASSOCIATION.

The American Pharmaceutical Association commenced its Twenty-second Annual Meeting in the Liederkranz Hall, Louisville, Kentucky, on Tuesday, the 8th inst. There was an attendance of about seventy members, including all the officers of the Society except one Vice-President. The greater part of the first day's proceedings consisted in reading the Report of the Secretary and Executive Committee, the nomination of various Committees, and the reception of Delegates. Twenty-two different Associations were represented, and other delegates were expected to arrive on the following day. At the close of the sitting, the President, Mr. John F. Hancock, of Baltimore, delivered an address in which he alluded to the practice of pharmacy, and gave advice concerning its practice to the members of the Association. The sitting was then adjourned until the next morning at nine o'clock. It is stated that the Association now numbers nearly eleven hundred members.

CAUTIONS.

A CORRESPONDENT, under the signature of "A VICTIM," sends an account of how he was persuaded by a woman to accept the sole district agency for a new night-light, and to invest some cash in laying in the necessary stock. After a time, however, he found that the lights went out, whilst two or three other "sole agents" became manifest in his immediate neighbourhood. The conclusion he has arrived at is obvious.

Mr. W. G. TAPLIN also writes to caution his brother chemists against purchasing a formula for pill coating, which has been offered by circular for 5*s*. He says that it is the same as was published in the PHARMACEUTICAL JOURNAL for May 30 last.

A PARIS pharmacien has been condemned to pay a penalty of five hundred francs for having sold some lozenges containing calomel, without an authority from a medical man. The Editor of the *Bulletin* of the Bordeaux Pharmaceutical Society pictures the surprise with which an anxious mother, seeking from a pharmacien some worm pastilles for the relief of a fractious child, would hear that she could no longer be supplied without first feeing a physician.

IT will be seen from our advertising columns that Sir PETER SPOKES, who acted for many years as the Local Secretary of the Pharmaceutical Society at Reading, is a candidate for the office of Director of the National Provident Institution, rendered vacant by the death of Mr. CHARLES GILPIN.

PROFESSOR GEORGE F. H. MARKOE, of the Massachusetts College of Pharmacy, who, it will be remembered, attended the Meeting of the British Pharmaceutical Conference at Brighton, in 1874, has been appointed Professor of Pharmacy and Materia Medica in the Medical Department of Harvard University. The appointment of a practical pharmacist to this post is considered by the *Tennessee Pharmacal Gazette* to be a step in the right direction.

MR. ARTHUR PEARSON LUFF, the Junior Bell Scholar during the last session in the School of Pharmacy, Bloomsbury Square, has been successful in obtaining one of the Science Scholarships at South Kensington which are offered as rewards to students who gain a high number of marks at the Science and Art examinations.

THE Court of Appeal, at Brussels, has recently confirmed a judgment which condemned Dr. CAMPENHOUT for having supplied his patients during three years with homœopathic medicines. The decision of the Court was based upon a law of 1818, by which a medical man is absolutely interdicted from practising pharmacy together with medicine, except in certain specified cases, even although he may hold the diploma of Doctor of Pharmacy. A medical man is not allowed to supply medicines to a patient even gratuitously.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

At a meeting of the above Society on the 5th August, under the presidency of M. Boudet, a letter from Mr. Lescher was read, inviting such of the members of the Society as were able to attend the approaching meeting of the British Pharmaceutical Conference in London. M. Mayet stated that M. Adrian, who had been invited personally, would attend the meeting, and would willingly undertake to represent the Paris Society of Pharmacy. After a short discussion it was decided that there was no necessity for a special delegation.

M. P. Vigier furnished a note upon the "épithème argilleux" which has been proposed by him for the dressing of wounds. The substance which he employs, a specimen of which was exhibited, is a mixture of fine moist clay (100 grams) and glycerine (50 grams), and the advantages claimed for it are that it adheres to the skin, does not putrefy, and is easily removed by water.

THE PHARMACEUTICAL CONGRESS AT ST. PETERSBURG.

PROPOSED UNIVERSAL PHARMACOPŒIA.

The following is a translation of the report upon the subject of the proposed Universal Pharmacopœia, presented to the International Congress on behalf of the Paris Society of Pharmacy by M. Méhu:—

For a long time there have existed in the different countries of Europe national pharmacopœias, which have served as an authority to pharmacists in the selection and preparation of medicines that have become sanctioned by science and experience; as guides to physicians in making them acquainted with the nature and composition of such medicines; as guarantees to physicians and patients for the regular preparation and uniformity of their composition in all parts of the respective countries, and as means of surveillance by the administrative authorities acting as the protectors of the public health.

These pharmacopœias were at first collections of empirical formulæ, conceived according to an order of ideas and considerations foreign to the spirit of modern science, and often inspired by prejudices more or less whimsical rather than by scientific ideas. But from the commencement of the present century they have acquired a new character, in harmony with the progress of modern chemistry and the precision of its processes and products, and with the development of the natural sciences.

The French Pharmacopœia promulgated by the Paris Parliament in 1748, under the name of the 'Codex Medicamentarius,' constituted until 1818, or during a period of sixty years, the law imposed upon the practice of medicine and pharmacy in France.

A new edition of the 'Codex Medicamentarius' was published in 1818. In 1837, the progress of science having rendered a revision of the legal formulary necessary, the government ordered the construction of a new pharmacopœia, which should sanction the reforms demanded by the state of science, and the new medicines by which the domain of pharmacology and therapeutics had been enriched up to that time. This work having in its turn ceased to be in harmony with the new wants of medical practice and recent discoveries in chemistry and natural history, the French Government, in 1861, confided the editing of a new Codex Pharmaceutique to a special Commission. This Commission, composed of professors of schools of medicine and of pharmacy, and members of the Academy of Medicine and the Paris Society of Pharmacy, was presided over by M. Dumas. The new Codex was published in 1866. It presents to pharmacists under a succinct form, and in precise language, a complete *résumé* of the rules which regulate the practice of pharmacy in France, and the formulæ of medicines which have received the legal sanction.

The work is divided into three parts. The first is devoted to general and preliminary matters; the second, to the materia medica, properly so called; and the third, to the pharmacopœia. The alphabetic order has been adopted for the materia medica, and the methodical order for the pharmacopœia.

The Commission of the last Codex, considering the rapidity of the communications established between the different peoples of the civilized world, and the facilities of their intercourse, so multiplied in the present day, thought that the French Pharmacopœia should not be limited to presenting to practicians the medicines necessary to medical practice throughout the French territory, but that it ought to be enriched by all important matters that could be borrowed from analogous works published in other countries.

Impressed also by the manifest tendency of Europe and the New World to adopt the metric system of weights and measures, the Commission already comprehended the great advantages that would be presented by a fraternal agreement between the pharmacists of the various States for the construction of a universal or international Codex. It therefore did not hesitate to give to its work a character more general than that of the Codex of 1837, and to perfect it by introducing a large number of formulæ borrowed from other pharmacopœias, and thus seek to provoke, by its initiative and example, all pharmacists to join in their views of the future unity of pharmacy.

This appeal has been heard. Numerous testimonies of sympathy have been addressed to French pharmacy, and the remembrance of the cordial reception of which its representatives were the object at the Congress at Brunswick in 1865 has encouraged it in its hopes of the international confraternity of pharmacists. The Paris Society, anxious to justify the confidence of the international committee from which it had received the honourable mission to organize a second universal congress at Paris in 1867, was induced to bring forward three questions for submission to the deliberation of that assembly as to the best means of constructing a Universal Codex or Formulary. The excellent report of M. Mialhe upon the question will not have been forgotten, nor the discussions to which it gave rise, and the consequent votes.

The general question of the Universal Codex was divided in the following manner:—(1) Ought the proposition for a Universal Codex to be adopted? (2) Ought the text to be written in the Latin language? (3) Ought the metric system of weights and measures to be adopted in it? To the first question the Congress answered in the affirmative unanimously, with the exception of the United States; to the second in the affirmative unanimously; to the third in the affirmative unanimously. Thus the utility of a Universal Codex was recognized, and it was decided that it should be written in the Latin language, and in conformity with the metric system of weights and measures.

Afterwards, at the third international Congress held in Vienna in 1869, the decisions of the Paris Congress were confirmed by a vote, in virtue of which the Paris Society of Pharmacy was charged with the preparation of the various elements of the composition of a Universal Codex.

Though the misfortunes of France for a long time arrested the Society in the accomplishment of the duty entrusted to it, scarcely had the country issued from its sad trials when the Society delegated to a committee of thirteen of its members the drawing up the plan of a Universal Codex, and the preparation of a scheme for editing it, intended for submission to the approbation of the next international congress of pharmaceutists. The thirteen members of the committee were:—M. Bussy, Member of the Institute, Director of the Paris School of Pharmacy, Honorary President; M. Boudet, Member of the Academy of Medicine, President; M. Buignet, of the Academy of Medicine; M. Duquesnel, of the Society of Pharmacy; M. Guichard, of the Society of Pharmacy; M. Jungfleisch, Assistant Professor of the School of Pharmacy; M. J. Lefort, of the Academy of Medicine; M. Mayet, of the Society of Pharmacy; M. Méhu, of the Society of Pharmacy, Secretary; M. Mialhe, of the Academy of Medicine; M. Planchon, Professor of the School of Pharmacy; M. Roucher, Pharmacien Principal de l'Armée; M. Wurtz, of the Society of Pharmacy. The results of the labours and deliberations of the Committee constitute the scheme for a Universal Pharmacopœia which is now presented to the International Congress of 1874.

The nearly unanimous adhesion of the Congress of 1874 to the French proposition of a Universal Codex, and the choice of the Paris Society of Pharmacy to prepare and draw up a plan, was doubtless a high testimony of esteem for the French Pharmacopœia of 1866, which had just appeared, and in which the idea of a Universal Pharmacopœia had been indicated by the illustrious author of its preface. The Commission understood the signification, and considered that it was so authorized to infuse into the Universal Pharmacopœia the plan of the French Pharmacopœia, or 'Codex Medicamentarius' of 1866. This plan is, in fact, as simple as it is rational, and more or less conformed to that of most European pharmacopœias.

The 'Codex Medicamentarius' of 1866 is composed of three divisions:—(1) Preliminary matters; (2) Materia Medica; (3) the Pharmacopœia. In the first division, under the title of "Notions préliminaires," is combined the information indispensable for a knowledge and employment of the metric system of weights and measures, the relations of the metric weights to foreign medicinal weights, the value in weights of spoonfuls, drops, pinches, and handfuls of medicaments; the apparatus most employed to determine temperature, the centigrade and Fahrenheit thermometers and the equivalence of their indications, densimetres, melting points, boiling points, and the solubilities of frequently employed substances. There is also in the first division a table of equivalents of simple bodies employed in medicine, either in their natural state or as combinations. The second division contains all that concerns the materia medica. The third division, the largest and most important, constitutes the Pharmacopœia, properly so called.

The International Codex Commission has not hesitated to follow the plan of the French Pharmacopœia, and act principally in conformity with its prescriptions in the execution of the work. The preliminary matters of the 'Codex Medicamentarius' comprise only scientific facts established by experience and accepted by the scientific men of all countries. These cannot be the object of any dispute, and consequently will give rise to no dissension between pharmacists of different nationalities; the only doubt in respect to them, considered in their relation to an International Pharmacopœia, would be concerning their comparative utility, and the degree of development which should be given to them in such a work. The French Pharmacopœia has shown itself very reserved in the choice of these preliminary matters, and the limits within which their exposition is confined; in the work which the International Codex Commission has the honour to present to the International Congress it has been even more strict than the authors of the French Pharmacopœia. The "Materia Medica" presents, in the most abridged form, the most certain information upon the origin and specific characters of substances which pharmacy has taken from the organic kingdom, upon the properties and characteristics of medicinal substances of inorganic nature, and upon chemical products, which pharmacists prepare in their own establishments or procure in commerce, and which, therefore, should find a place in the "Materia Medica." The means of testing the purity of these products, and of preserving them, are indicated with particular care.

Under this title of "Materia Medica" the Commission has only included the substances and products of which the generally diffused usage in one or more European countries would render their adoption in an International Pharmacopœia justifiable.

The first two divisions of the work of the Commission, the "Preliminary Information," and "Materia Medica," belong to the domain of pure science, of that science which, like truth, is not the privilege of any people, but constitutes a domain common to all. Agreement, therefore, already exists between all the pharmacists of all countries upon the basis of this important portion of the Universal Codex, and if it could produce any disagreement this would have reference only to secondary matters that would be easy to decide.

The third portion of the Codex, the Pharmacopœia properly so called, as conceived by the Commission, raises problems much more numerous and delicate than the first two. Here the work is no longer to make a judicious choice from certain facts common to all nations, but to select from a great number of formulæ,—established more or less empirically and arbitrarily, and under the influence of most diverse considerations—which form the particular formularies or special pharmacopœias of the nations of Europe a collection of formulæ that will respond to the general wants of the art of healing, taking account of the special constitutions and usages of the different nations, and which, at the same time, shall be conformed to the precise rules that science has introduced into pharmacology. This programme is certainly difficult to fulfil thoroughly in such a manner as to avoid all the rocks that it presents, to give satisfaction to all interests and opinions, and to obtain the suffrages of the pharmaceutical body of the civilized world.

But the Society of Pharmacy, and the Commission which it appointed to prepare the accomplishment of this delicate work, have calculated upon the elevated and generous ideas of pharmacists, the methodical spirit and scientific sentiment by which they are guided in the exercise of their profession, and of which the pharmacopœias published in later years by the different nations of Europe bear incontestable and profound impress. They have also found encouragement in the wonderful accord which was manifested at the Congress in Paris in 1867 between all the pharmacists who took part in the unanimous vote which decided the compilation of a Universal Codex. Had not the vote, in fact, a great significance? Did it not show that the moment had come for pharmacists to establish, for medicines and their formulæ, the unity and universality which exist for other sciences, and to transform all the national pharmacopœias into a Universal Pharmacopœia, as they had already transformed all the collections of recipes or particular formulæ into national pharmacopœias?

Experience and time have led the teaching and practice of medicine to follow nearly everywhere the same road; their progress in all countries is simultaneous and conjoint with that of physical and chemical science. In the present day there is not a discovery, a fact, an observation in the field of medical science, that is not immediately known, submitted to the control of experiment, and discussed and applied more or less usefully in every civilized country, nearly as rapidly as in the provinces of a single empire.

In the midst of such evident manifestations of the simultaneity and unity of scientific movement in the civilized world, should not the numerous, yet often so baseless and insignificant, differences which exist between analogous medicines be made to disappear? The elements of which these medicines are formed, whether they belong to natural or chemical products, being determined according to the same scientific principles, why should they be submitted to different processes to be elaborated into medicines? If it be sought to extract the most active portions of certain vegetable substances by the aid of solvents, or to prepare solid or liquid extracts, tinctures, etc., ought not the best established scientific principles to be everywhere alike taken into consideration, to determine the processes to which these substances should be submitted, the nature and properties of the solvents to be employed, the temperature at which they should be used, and the proportion of product to be collected? If it be proposed to separate immediate principles—organic alkalis, for example, from plants that contain them—is it not according to the general and universal rules of chemistry that one should proceed to their preparation and to test the purity of the products obtained? Does not the same remark apply, with much stronger force, to the preparations which belong more especially to the department of industrial chemistry?

As to compound medicines which result from more or less complicated mixtures of simple or compound substances, such as syrups, electuaries, pills, draughts, mixtures, pomades, ointments, plasters, etc., it is evident that their numerous, complicated, arbitrary, and irrational formulæ of past times are already reduced in national pharmacopœias to simple, logical, and truly scientific terms, and that it is to the reduction to a single formula of the analogous formulæ still designated under different names, to the elimination from these formulæ of the ingredients recognized as useless, to the better definition of the choice and characters of those recognized as necessary, and to rendering more correct the manipulations which relate to them, that all the efforts of pharmacists should tend. If this be the case, and if in all European countries the principles of science and pharmacology are the same, if the tendency and direction of progress are the same, if, moreover, all national pharmacopœias bear already the deep impress of these principles and tendencies; why, resting upon these universally recognized truths, should it not be possible to gather together into our common work all the positive information, all the impartially proved progress of general pharmacology, and to prepare thus for all nations the common enjoyment of all the advantages that the particular pharmacopœias have been able to realize for each of them?

Certain medicaments, brought forth mysteriously in the spirit of speculation and luxury rather than by the love and genius of science and true progress, have acquired in the present day a universal notoriety and currency; the venal and conscienceless voice of the press has praised them and propagated their use throughout both continents, and they are there in request in spite of the local habits and special constitutions of the populations. Why should not the medical men and pharmacists of all countries seek in common accord, and by a vigorous and noble alliance, to oppose to these empirical medicaments, which tend to the revival of the panaceas and arcana of former centuries, those rational medicaments, known to all, in their elements and properties sanctioned by science and universal experience, which offer to the art of healing certain well-tempered weapons of constant uniform and measured energy, and which in their totality constitute the regular arsenal of true medicine? What means would be more powerful than the promulgation of an International Pharmacopœia to cause the disappearance of these mysterious and often injurious productions, before the legitimate, patent, and truly scientific conquests of which a Universal Pharmacopœia should be the most exact, clear, and complete representation?

Of what weight are these pretended discoveries of secret remedies if they be compared to the discoveries of pharmaceutical science,—if they be compared to those of morphine, codeine, quinine, digitalin, aconitine, iodine, bromine, chloroform, etc., the greater part of which have been given to humanity by pharmacists? Who will remember the former some years hence when they shall have been replaced by new conceptions of a similar value? Whilst the second, made fruitful by time, experience, and the researches of truly scientific men, will have acquired new titles to the gratitude of mankind.

Sustained and directed by the considerations and principles above set forth, the Society of Pharmacy and the Commission set to work with confidence in the success of their enterprise, and with the firm hope of obtaining the assent of the association and societies of pharmacists for which they were acting. The following was their mode of procedure:—The members of the Commission first studied and compared with great care the pharmacopœias of Europe and America, those, namely, of Germany, Great Britain, Austria, Belgium, Denmark, United States, France, Greece, Holland, Moldavia and Roumania, Sweden and Norway, and Switzerland. After this preliminary study, they have decided, after an exhaustive discussion, upon the general plan of a Universal Codex, to which each contributed his part. Finally, the individual work of each collaborateur was discussed by the entire Commission, and definitely adopted for submission, in the next place, as a whole to the Society of Pharmacy.

In the selection and editing of the formulæ, the Commission endeavoured to give the preference to the simplest, most rational, and most used, without distinction of origin. Profoundly imbued with the views that prevailed in drawing up the French Pharmacopœia of 1867, the Commission has naturally been led to propose a great number of matters and formulæ borrowed from the national pharmacopœia, but it has made it a duty, on all occasions when it has had to choose between a French and a foreign formula nearly equivalent, to give the preference to the latter.

The Commission considers its work to be essentially provisional; it is only a work offered for the appreciation of the Congress, and each member of every pharmaceutical nationality is entirely free to criticize the propositions, and to combat and seek to make prevail the particular ideas and prescriptions of his national pharmacopœia. The lists are open to all contradictions, and it is from the shock of diverse opinions and their independent discussion that should issue the common work of the pharmacists of all nations.

May you, gentlemen, and most honoured *confrères*, find, in the work which the Society of Pharmacy submits to your judgment, the proof of its energetic devotion to the consideration and honour of pharmacy! May you there recognize the plan and foundation of a general pharmacopœia which shall respond to your wishes, experience, and profound science, and confirm you in the conviction that it is possible to compose a Universal Pharmacopœia which shall be a pharmaceutical monument of high importance, which, whilst leaving to the pharmacists of all nations the free exercise of their national pharmacopœias, will permit them to execute faithfully, without uncertainty or hesitation, and with perfect security, the prescriptions of medical men of all countries, and which will constitute a true and valuable advance in the art of healing, in the relief of the suffering, and the facility of international relations.

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

The Colour of Preserved Peas.

At the Liverpool Police Court, on Wednesday, September 16th, before Mr. Raffles, stipendiary magistrate, Messrs. Beckett, Alty, and Co., grocers, etc., 8, James Street, were summoned for selling peas which were mixed with a material injurious to health. Mr. Atkinson, the deputy borough solicitor, supported the information, and Mr. Bremner defended. Mr. Atkinson stated that the case differed from any previous charge of adulteration that had been brought before the court. On selling the peas the servants of the defendants stated that they were coloured or adulterated. Had the colouring matter been of an innocuous character, the defendants, after this, could not have been summoned under the Adulteration Act; but the second section of that Act provided that, even if notice were given of the adulteration of any article, the person selling it was liable to a penalty if it were injurious to health. Certain French firms sent over to this country large quantities of preserved peas, of two kinds, coloured and uncoloured, and which were in great request. He believed the uncoloured ones were perfectly harmless; but some persons were not satisfied with them unless they were coloured green, and in order to meet this demand some of the peas were coloured green by means of copper. One of the inspectors had purchased a tin of these green peas at the defendants' shop, and on being opened it was found to contain a large amount of copper. He contended that if the defendants knew that the peas were coloured it was incumbent upon them to inquire by what means the colouring was effected, and it was therefore fair to assume that the presence of copper amongst the peas was known. He produced an ordinary steel needle thickly coated with copper, showing the result of its being allowed to remain amongst the peas for a short time. Mr. Raffles observed that it must be shown that when the defendants sold the article in question they knew that it was injurious to health. It might be that they thought the peas were coloured with a perfectly innocuous material. Mr. Atkinson thought it was the business of the seller to ascertain in what manner the peas he sold were coloured. Mr. Bremner said the defendants had had no knowledge of the injurious character of the peas; but, on becoming acquainted with the fact, the sale of the peas was immediately stopped. Mr. Raffles said he thought a person should certainly ascertain how peas were coloured; but it was not shown that the defendants knew it. He would, however, after the publicity which would be given to this case, be disposed to convict anyone else that should be brought before him similarly charged. The case was then dismissed.—*Grocer*

Adulteration of Brandy.

An innkeeper of Yeovil, by name David Smith, was lately summoned under the Adulteration Act for selling adulterated brandy. The public analyst for the district sent in his certificate of analysis of the brandy in question, stating that it had been adulterated with tannic acid, iron, sugar, and colouring, and further asserting that the consumption of such an article would be injurious to health. For the defence, Mr. Davies contended that brandy was an article not fit to be sold in its raw state, and that it was well known that manufacturers "used sundry devices for making it palatable." He further described the spirit as being "essentially a compound," and stated that even the famous French cognac, whose virtues are so generally lauded, was "a liquor obtained from beetroot, flavoured with cognac oil and sugar." After thus ingeniously attempting to show that his client had sold the usual article of commerce, the Yeovil advocate reverted more especially to the stern facts of the case, and mentioned that the defendant had paid 25*s.* a gallon for what he considered a pure article, and that the brandy was sold in the same condition as received by the retailer. Notwithstanding the vigorous defence of his legal representative, the Yeovil innkeeper was fined 2*l.* and costs.—*Grocer.*

Important to Soda Water Manufacturers.

On Wednesday, September 16, at the Longton police-court, before H. C. Greenwood, Esq., stipendiary, Mr. Samuel Taylor, soda water manufacturer, Longton, was charged with selling half a dozen bottles of adulterated soda water. The point raised was whether the soda water could be said to be adulterated by being devoid of bicarbonate of soda, and thus depriving the customer of the benefits to be derived from the active ingredient which it should have contained. The county analyst had certified that in this particular case the water analysed was devoid of the smallest particle of soda, and only contained water and carbonic acid gas. The wife of the maker swore that he being busy she herself superintended putting the soda into the bottles, and that each bottle contained the required quantity. The informations were dismissed, the stipendiary deciding that the act did not apply in this case, holding that to adulterate there must be an adding to, while in the case before him there was a taking from. A case was asked for by Mr. Tolford, counsel for the prosecution, and granted.—*Manchester Courier.*

Death from Hydrate of Chloral.

Dr. Hardwicke, the deputy coroner for Middlesex, held an inquest three days ago on the body of Mr. Charles Dawson, a law student, who died in consequence of taking an overdose of hydrate of chloral, which he had taken for the purpose of inducing sleep. Mr. Lucas, resident medical officer of Middlesex Hospital, stated that the deceased was admitted by Mr. Sydney Coupland, and expired six hours afterwards. Witness received from him a bottle containing "Improved Syrup of Chloral-Hydrate." The *post mortem* examination showed that the left ventricle of the heart was in a state of fibrous growth, which destroyed the muscular tissue, and there was also the remains of old peritonitis. The cause of death was the condition of the heart, accelerated by taking a dose of chloral. A rough analysis was made, which showed that the preparation was weaker than the usual strength sold by chemists and druggists. The jury returned a verdict of "Death from heart disease, accelerated by taking a dose of hydrate of chloral, which was uncertain in its action."—*British Medical Journal,* September 19.

Suicide of a Chemist and Druggist.

An inquest has been held in Manchester by the city coroner, upon the body of William George Searle, chemist and druggist, of 132, Upper Brook Street. From the evidence it appeared that the deceased had been unsettled in his mind for some time past, and after a slight quarrel had gone to his room, locked the door, and taken some prussic acid; the door was forced open, and deceased was found lying on the bed with the poison bottle in his hand. A verdict of suicide whilst in a state of insanity was returned.

The Prosecution for Embezzlement at Liverpool.

We have been requested to state that the Mr. J. Thompson referred to in the report, on p. 238 of last week's Journal, of the prosecution of two young men at Liverpool for embezzlement, is not in any way connected with Mr. J. Thompson, of 121, New North Road, London.

Review.

Nouveaux Éléments de Pharmacie, par A. Andouard, Pharmacien, Professeur de Chimie à l'École de Médecine et de Pharmacie de Nantes, membre du Conseil d'Hygiène et de Salubrité; avec 120 figures intercalées dans le Texte. Paris: J. B. Baillière et Fils. 1874.

"They manage these things better in France" is a saying as true in respect of pharmacy as it would be misapplied in speaking of government. If our mercurial neighbours cannot be said to march in the van, yet are they very far ahead in the general progress towards pharmacy as it should be, which we have in a manner just joined. Perhaps this is shown in no way more clearly than by a comparison of the literature of the two countries. Of English books on general pharmacy there are literally none, and in those works which do treat of it at all, as some of our text-books on materia medica, it holds a very unimportant position. This is not due to the want of men competent to deal with the subject, but to the want of a demand for information on a science respecting which we scarcely know as yet that we are ignorant. The need for this information is being now felt for the first time among British pharmacists, thanks to the leaven of the British Pharmaceutical Conference which is gradually spreading through the mass. That the need will be supplied in due time we cannot doubt. Meanwhile the immediate supply is furnished by France and Germany, but especially the former, chiefly because of more ready communication with this country, and because French as a language is more commonly studied among us than German is. French works on pharmacy are numerous, as our columns of reviews show. Most of them are good, many are excellent, and the one now before us is one of the best and most complete. M. Andouard is a pharmacien, and *au courant* with his subject, which he treats at the same time with a comprehensiveness and a minuteness leaving little to be desired.

In his preface the author expresses dissatisfaction with the dictionary definition of pharmacy,—*the art of preparing medicines*, and we agree with him that to define it as *the science of medicines and their preparations* would be more exact. For, says he, the pharmacist should know not only how to manipulate medicinal substances, but also he should know whatever refers to their physical and chemical properties, to the changes they undergo, and to the adulterations to which they are subject. It is evidently in sight of this view that the facts have been collected and the book written.

Now for a general view of the volume and its 884 pages. In treating of a science such as pharmacy, which has to do with so many substances of such diverse nature and composition, a good classification is all-important; if simple as well as sufficient, the science gains by it. The classification devised for the book before us certainly has the merit of simplicity—it may also be sufficient. Whether it is so or not will appear on use. It is possible that the fact of M. Andouard being professor of chemistry to the school of medicine and pharmacy at Nantes, may have something to do with the other fact that he regards chemistry as the soundest basis of pharmacal classification. Be that as it may, medicinal substances are first separated into those whose exact chemical composition is known, and those of which the composition is known only approximately. The first series comprises *simple bodies, mineral or inorganic compounds* and *organic compounds.* The second series is much more numerous, and includes *powders, pulps, juices* and *species*, the medicines obtained by means of *water, alcohol, glycerine, ether, fats, essences, wine, vinegar,* and *beer* respectively; and lastly, medicines which are formed by admixtures of any of the preceding, viz., *pills, capsules, liniments,* and *fumigations.* The first series is preceded by a lengthy chapter of a most exhaustive and minute nature, on pharmaceutical operations, the comprehension of the text being aided by an almost lavish use of very good woodcuts. Under the head of weighing and measuring is a table showing the relation of foreign weights used in medicine to the French gramme. Under this head also is an examination into the merits of *compte-gouttes*, followed by the common-sense conclusion that they are defective and untrustworthy.

The second series is introduced by directions for the choice and collection of animal and vegetable substances, their drying and preservation. This chapter, as indeed the whole book, is characterized by painstaking care. The subjects of extracts, tinctures, syrups, etc., are each introduced by a chapter discussing the general *modus operandi* of preparing before passing on to treat of the preparations in particular. In the classification of salts the acidulous radical is made to mark the genus, and the basylous the species. The effect of this is to distribute salts of the same base all over the book. Thus, sulphate of iron is found at p. 264, the carbonate at 213, sulphide at 182, and the chloride at 201. This is not so convenient, and does not seem to us so natural, as to employ the basylous radical for co-ordinator.

The mode of preparation of every definite chemical body is given, then come its purification and chemical and physical properties, followed by the mode of estimation and pharmacology. Under the latter heading appears every preparation of the body in the Codex, and other approved formulæ, with critical remarks wherever they seem to be called for. Twenty pages are given to the consideration of water in all its forms, soft, mineral, gaseous, aërated, etc. This is a fair proportion of the entire volume, yet not too much. The same sound judgment seems to have guided the author throughout his work; everything receives adequate mention, and we should not suppose that any part of the book is a favourite subject with the author. It is written as though from a student's standpoint, with a just appreciation of what he requires. There is nothing new to be found in it, at the same time we notice no important omissions.

It is to be deplored, however, that the work is not abreast of the times in the matter of nomenclature. The new atomic weights and molecular formulæ are so very generally recognized now that to disregard them in a handbook treating of chemistry must necessarily restrict both circulation and usefulness.

With this exception, the book before us is such as we would wish to see in the hands of every pharmaceutical student. Its equal is not to be found in English, and there is little question that an English edition would repay both translator and publisher.

BOOKS RECEIVED.

The Contrast between Crystallization and Life. By John Eliot Howard, F.R.S., etc. London: Hardwicke, 1874. From the Author.

How to Restore the Walking Powers and Muscular Movement Generally. By F. Graham Bennett, M.R.C.S., etc. Second Edition. London: Whittaker, 1874.

Notes and Queries.

[408.] OILED SILK. — Can any one inform me concerning the process for the manufacture of oiled silk? Also the difference in preparation between the English and the French make, the latter being so much softer than the former?—John Edkins.

[409.] DEPILATORY.—Wanted, a formula for a satisfactory depilatory without unpleasant smell.—W. W.

[410.] MARKING INK.—I shall feel obliged if any one will give a good recipe for marking ink—one which will turn black at once without heating.—M. F. Thompson

[411.] COMPOSITION ESSENCE.—Will any correspondent supply me with a formula for Composition Essence?—Querist.

TEST FOR ARSENIC.—MM. Mayençon and Bergeret describe (*Rép. Pharm.* ii., 497) a new method for the detection of arsenic in organic and inorganic substances, which they consider to be superior to Marsh's test. It is founded upon a reaction of arseniuretted hydrogen upon bichloride of mercury, which has been represented by H. Rose as—

$$6\,HgCl + AsH_3 = 3\,Hg_2Cl + As + 3\,HCl.$$

If a piece of paper moistened with a solution of bichloride of mercury be exposed while wet to the vapour of arseniuretted hydrogen a spot is produced, which is at first of a citron yellow colour, but afterwards darkens to a pale yellow brown. Antimony, on the other hand, gives rise to a grey brown spot, which is clearly distinguishable from the arsenical spot. The test is said to be extremely delicate.

The New Regulations.

Sir,—May I venture to ask your indulgence, and also to request that you will allow me a short space in the Journal to say a few words on the above subject. I believe the new bye-laws relative to the alterations and amendments of the examinations take effect at the October meeting of the Board, thereby rendering them, if possible, more practical than they have ever been, and it occurred to me the time might not be inopportune for reverting to the oft-repeated subject, the relative positions of a pharmaceutist and chemist and druggist, or, as some of our friends have it, chemist by examination.

The Major alone constitutes the right of all future pharmaceutists, and in order that they may hold a position known to the public—as higher than simply Member of the Pharmaceutical Society or Chemist and Druggist—some are advocating all sorts of additions and appendages, not only as an inducement to all Minors to become Major men, but also to secure to pharmaceutists the most elevated post in the eyes of the public as scientific men.

We all know that education elevates, refines, and raises all classes, be they men or women; and we have proof of the high estimation in which many pharmaceutists are held as chemists, by their being now constantly appointed public analysts in large provincial towns and districts, where hitherto such appointments were always carried off by members of the medical profession. This, therefore, we must all rejoice to see, as it is a step upward and onward.

It is not my province on this occasion to deal with pharmaceutists so much as non-pharmaceutists, having myself gone through the prescribed course. I may, perhaps, be excused for saying that the Major *vivâ voce* examination was one of the most pleasant and interesting meetings I ever attended, and conducted in the kindest and nicest manner possible. I say this to cheer some of our friends who may be candidates for the next meeting of the Board, and fearing that they might be, as Professor Bentley used to say, "a little nervous."

My object now is one of persuasion; to endeavour, if possible, rather to dissuade young men from accepting the Minor qualification as a fit and proper one for going into business. For my own part, I may say I feel with gratitude more and more every day the value of the information one gets in working up for these examinations, and I am glad to see that these are being elevated more and more. But it seems to me a very serious matter—as statistics prove—that so many pass the Minor and never go further; as they say, they rest and are thankful. But this resting on one's oars, or rather resting, as it were, in sight of the goal, is surely a bad thing, and I am very much disposed to advocate, not so much that there should be a very wide difference between the two examinations, as that the Minor should be considered essentially an Assistant's examination, and, as such, should not entitle its holder to enter business on his own account; then we should have no difficulty in getting all to go through the whole thing, and the question of grades in the future would be done with.

Time was when many firms would say—"Give me a man who knows his business; never mind about the Pharmaceutical Society." But times are now when educational requirements and demands have pushed the Pharmaceutical Society to the front, and the Society owes to itself jealousy for the proficiency of its members. If therefore it were possible to alter and amend the Pharmacy Act so that the Minor had to be passed by all assistants above the age of twenty-one years, and should be considered the first half, then it would, I think, be found that there was not the same difficulty or lack of members for the Major.

There is such a common feeling with us all to ask, Is this or that necessary? can we not do just as well by omitting this and only doing that? Once let us have the law that all men shall pass the Major examination before entering business, and we should then find the controversy relative to the two grades at an end. At the same time it would of course be necessary, as some of our friends in the sister isle would say, to preserve all existing rights to the present generation, and the future representatives of pharmacy would be all on one footing.

ARTHUR W. POSTANS.

35, *Baker Street, W., Sept. 22nd,* 1874.

THE JOURNAL OF THE CHEMICAL SOCIETY.

Sir,—Perhaps your columns offer as appropriate a place as any to remark on the—shall we say—platinum wire rather than red tape rigidity which binds down the able editor of the Journal of the Chemical Society, cramping him down in fact to the office of a mere corrector of the press. Surely the editor is worthy of having a more prominent place than simply to fill up one line of the cover of the Journal. Is it a minority of one only that considers some editorial reviews of progress, and at least a condensed digest of the discussions at the meetings of the Society, would be an interesting acquisition to the Journal? Every one familiar with the London learned societies must be aware that frequently discussions on papers read are far more interesting than the papers themselves, embodying as they often do the thoughts and criticisms of the foremost men of the day. Why should these thoughts be monopolized by the fortunate few who can attend these meetings? It may be inexpedient, perhaps, to follow the example of the Society of Arts and give a full report of these discussions, but what is pleaded for, is a little more elasticity, so as to admit of a little editorial work and responsibility. At one time, there were occasionally rather shy and modest glimpses of discussions, but even these appear to have vanished. Is there not also room for a limited portion of correspondence, so that involuntary absentees, and others, may give a few hints and remarks on subjects that have come before the society?

W. SYMONS, F.C.S.

Barnstaple.

KAURI GUM.

Sir,—I have long had such thoughts as those expressed in the preceding letter, but the topic which led me to put them on paper is Kauri Gum (*vide Journal of Chemical Society* for August). I have no claim whatever to assume to be an authority on the matter, but a visit to New Zealand a few years since naturally gave the opportunity for forming a slight acquaintance with the article. In Mr. Muir's paper he truly says, "It is largely imported into this country," and yet in his last paragraph he implies he has only been able to procure a small specimen. How is this? Is he speaking of two different articles? It may be so, but nothing in his paper implies this. His first remark is, "The gum or resin *exudes* from a tree." If the gum he has examined exuded from a tree this year or last, or within ten or fifty years, it is a different article to that which may be seen on the Auckland wharf frequently in scores, if not hundreds of chests. There appears little doubt that the Kauri Gum of commerce did exude rom the *Dammara Australis* or some similar pine, but surely before Captain Cooke was born; it may have been five thousand, or even five hundred thousand years since. Colonial dealers in the gum declare that the semi-fossilized article, which is the only one known in commerce, essentially differs from the gum which may be collected from the existing Kauri trees. This is certainly a point which may well engage Mr. Muir's attention, viz., in what way gum collected from growing trees differs from that dug up in the barren wastes, of which thousands of acres exist in New Zealand, and seem not to have any value whatever, except from the Kauri Gum which may be found under the surface.

It has been my lot to perambulate such a district at Mangawhai, which a grateful country gave to some military veterans, no doubt with the idea that (barring the Maories) they could now end their days, each man under his own vine and fig tree; but with almost the solitary exception of a Major, who keeps a wooden hotel, the ungrateful recipients have vanished, leaving little behind but what they found, a hungry desert of white clay, fifty acres of which would support neither a goat or a donkey. It is just in such districts the Kauri Gum is found. Nothing scarcely grows on it but the "ti" shrub, which is too bitter for any animal to touch. The only signs of life are a few grasshoppers and crickets, with now and then a solitary mute native lark. The presence of Kauri Gum in the soil seems to show that at some time, but distant enough to be a geological question, forests of the noble Kauri pine must have existed there, and have abstracted all the potash and other fertilizing elements which have since been washed away, leaving nothing behind but an expanse of hungry white clay, scattered over with the well-known shrub which proclaims the barrenness of the ground.

I would be far from implying that such scenes are general, even in this part of New Zealand; but what constitutes the difficulty of New Zealand settlers, at least in the north, is, that the good land is covered with forests still. There are thousands of acres such as I have described, the Kauri Gum being of little value to the nominal owners, as while it is hardly considered the right thing for white settlers to dig for gum on any native land, the Maories take it for granted that all unenclosed land is free for them to dig over. Gum-digging just suits Maori habits. They are averse to the necessary and continuous labour of cultivating the land. As an instance of this, a missionary, who had induced some of them to keep cows, told me that after a time one came to him and asked, "How long am I to be a slave to my cow?" But gum digging can be taken up at fits and starts, and the gum turned at once into money or bartered for provisions, etc. It is also the last resort of broken down colonists above the grade of labourers. They manage to buy the one tool necessary, and start gum digging.

In some outlying districts, money would be scarcely seen or circulated but for the little trade and commerce arising from supplying the gum diggers with provisions, etc. Large as is and has been the produce, it must in time cease, and then these tracts of country will indeed be worthless, unless lying fallow for a century or two will restore to them some little fertility. This seems to be the only hope, remote as it is, unless the "ti" shrub (pronounced *te*) may be utilized. The small hard leaves and twigs have an aromatic bitter taste, and I would suggest to Mr. Muir or some other investigator to examine the properties of this shrub. Should it be valuable as a medicine, New Zealand can supply the world.

Kauri is pronounced Kowri, as Maori is pronounced Mowri. The gum is sometimes found in large pieces. The colour varies from a soft cream white to amber, sometimes clear and occasionally prettily veined. It is frequently carved into ornaments of various kinds. As a memento of two or three pleasant days spent on the singular and many branched tidal estuary of the Kaipara, I had a heart; but I lost it somewhere crossing the Pacific or America, perhaps at Salt Lake City, where I staid a night. This heart, however, was a bought one, purchased from an almost hermit brother of a London R. A., who also had some artistic ability utilized in painting pictures, also doors and windows, for the *élite* among the settlers.

If cross-examined on oath, I should hesitate in saying so, but still my impression is that selected Kauri Gum sometimes passes for amber. It is a question for discussion whether this would be an adulteration to be brought under the cognizance of our official analysts of whom we hear so much. As amber mouth pieces are used in connection with tobacco, this may be a link for adding it to the list, and as many of the appointed analysts are among your readers, perhaps they will make a note of it for discussion at their next meeting. A preliminary, but difficult question, however, will require to be settled first, viz., is tobacco meat, drink, or medicine?

W. SYMONS.

Barnstaple, 25th August, 1874.

AMMONIACAL FISH.

Sir,—The remarkable property of the skate or ray in developing ammoniacal gas during the process of drying is shared by other cartilaginous fishes, particularly by the genus *Squalus* (sharks), as any person familiar with fishing towns and villages on the Kentish coast must have noticed when passing a fish-curing establishment, where may be seen and smelt rays, riggs, and sweet williams.

The former are not unlike the white shark in habits and appearance; have the largely developed dorsal fin, harsh skin, and ferocious aspect. I have frequently seen, at Jersey, a cartload of them pitched down in the market, writhing in horrible contortions, opening and shutting their villainous-looking eyes with malignant expression. Terrible stories are related by fishermen about these monsters of the deep, but the *ichthyophagi* like them none the worse for having fed upon human flesh.

The sweet william, so named on account of its more delicate flavour, like the basking shark (*Squalus maximus*), has nothing of the ferocity of its congeners, a fact that may be taken as corroborative of its complimentary title.

The dog-fish is another and smaller species of shark, regarded with unmitigated hatred by fishermen, who bring them ashore merely for the sake of destroying them. These fish swarm round the shoals of herrings, sprats, etc., and getting entangled in the net, "shake and tear it like a dog," thus not only effecting their own escape but endangering loss of the haul.

A peculiarity is noticed by Cuvier in reference to the cranium of the sharks; the sac which constitutes part of it "contains mere amylaceous masses, and not stones."

As dog-fish may be had for nothing, and would perhaps yield as much trimethylamine as good wholesome skate, it might be worth while for manufacturers to secure a cargo, hitherto of no value except for manure.

Neither the sharks nor the rays possess scales, the skin of the former being covered with spiculæ, while the ray is slimy.

The idea that any *gourmets*, however deficient in good taste, could eat "hartshorny" skate, is past belief. I remember, when a boy, that some skate was brought to table, and was sent away on account of its pungency. The fish acquires this odour after having been kept a short time, when it again becomes sweet, and cooks say it is all the better for keeping.

If any one desires to preserve skate after the style of Finnan haddock, he would succeed better than did Mr. Groves in his experiment by adopting the plan of smoking. The acetic acid evolved during the combustion of the wood, combining with the ammoniacal gas, would prevent decomposition.

Whether trimethylamine will ever be recognized as more than a passing experiment in therapeutics, or whether, like "our little systems have its day, and cease to be," consigned to the Tophet of volatile alkali distilled from human bones, with which the doctors dosed poor Charles I., the moss from a dead man's skull, the Græcum album, and more lately the excretæ of serpents, remains to be proved. I have not yet met with a practitioner who knew anything respecting the efficacy of the new remedy, or who even recognized its name.

R. GOODWIN MUMBRAY.

Richmond, Surrey.

"*Associate.*"—It is necessary, in order that green extracts may be elegant, efficacious, and at the same time possessed of good keeping qualities, that the chlorophyll and extractive be combined in certain proportions. If the leaves only be used the chlorophyll will be in excess, while if the stalks and upper stems be selected, the extractive will preponderate, and the completed product will be deficient in colouring matter. The use of leaves, branches, and upper stems produces an expressed juice, which when treated by the officinal process gives an elegant extract.

A. J. Knight.—"Salaratus," we imagine, is intended for sal aëratus. Both bicarbonate of sodium and carbonate of ammonia are used for the purpose indicated.

W. A. Maggs.—Iridin is an oleo-resinous substance obtained from the rhizome of *Iris versicolor* (Blue Flag). It is one of the eclectic remedies, and you will find accounts of it in American works on materia medica.

G. W.—You are right in supposing that the plant is a white variety of *Calamintha clinopodium.*

G. Broom.—We have already expressed our determination not to insert any more correspondence on the subject.

S. C.—Since the issue of the British Pharmacopœia, sumbul has been determined to be the product of a species of a new genus of Umbellifereæ, which has been described by Kaufmann, under the name of *Euryangium Sumbul.* Galbanum also is now known to be derived from *Ferula galbaniflua,* Buhse.

A. E. Tribe.—Probably the substance inquired for is dynamite.

Messrs. Young and Postans.—See an article on Goa Powder in the second series of the *Pharmaceutical Journal,* vol. v., p. 345.

K. K. K.—*Essence of Musk.*—The following formula is given in Cooley's Cyclopædia as yielding essence of musk of the very finest quality:—

Musk (from the bladder, rubbed very small), 5 oz., civet 1 oz., essence of ambergris 1 pint; 1 gallon. Digest with frequent agitation for two months, in the sunshine in summer, or in a warm place in winter; decant and filter. The addition of 1 fl. dr. of liq. ammoniæ to each pint of essence increases its fragrance. The same authority states that the essence of musk of the London wholesale druggists is generally made by merely digesting the freshly emptied musk pods in rectified spirit.

"*A Father.*"—We do not feel at liberty to insert your letter, notwithstanding your offer to take the responsibility. The practice may be as you say, and, if so, it would be blameable, but it would be difficult to prove in the face of a denial.

Nemo.—It is undoubtedly intended to be an eight-ounce mixture. Literally it might perhaps be construed into twelve, but such was never in the mind of the prescriber. Had there only been an ounce of infusion in place of four, there would not have been the shadow of a doubt; but as we have often seen a prescription commenced with ℞ Inf. gentianæ co. ad ℥viij, we give our verdict in favour of an eight.

"*Nemo.*"—(1) The cheapest, especially if the ink is to be sold for 6*d.* But whether the cheapest or the dearest be employed, it will be found that purple solutions are not necessarily purple pigments. (2) Many experiments have been made with aniline blue dyes in the manufacture of marking ink, but always with one result; the blue colour lasts for twenty-four hours, when it gradually changes into what Lady Morgan called "a dun ducketty mud colour." (3) If our correspondent desires to colour his marking ink blue, he would confer a great benefit on himself and on many others who desire the same thing by consulting through some simple medium the acute spirit of the late Mr. John Bond.

J. J. Harvey.—We have received your communication, too late for insertion in this number of the Journal. We are glad to learn that you have submitted the question to the authorities at Somerset House, and until a reply has been returned we do not think it would be desirable to publish your letter to us.

"*A Correspondent.*"—The '*Veterinarian,*' published by Longman and Co., is the only existing English veterinary journal. It appears monthly, and the price is 1*s.* 6*d.* a number.

Mr. W. Wilkinson is thanked for his communications.

NOTICE.—Considerable inconvenience and disappointment are frequently caused by neglect of the regulations as to correspondence, letters intended for the Editor being sent to the Publishers or the Secretary, and *vice versâ.* A compliance with the explicit instructions published weekly over our Editorial columns will prevent delay, and the consequent annoyance.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. L. E. Bore, Mr. B. Proctor, Mr. Thompson, Mr. J. W. Yates, Mr. Tichborne, Mr. Shaw, Mr. Bennett, Mr. Davies, W. H. F., W. H. L., W. W., R. G. B., "Nil Desperandum."

The following journals have been received:—The 'British Medical Journal,' Sept. 19; the 'Medical Times and Gazette,' Sept. 19; the 'Lancet,' Sept. 19; the 'London Medical Record,' Sept. 19; 'Medical Press and Circular,' Sept. 19; 'Nature,' Sept. 19; 'Chemical News,' Sept. 19; 'Gardeners' Chronicle,' Sept. 19; the 'Grocer,' Sept. 19; 'Journal of the Society of Arts,' Sept. 19; 'Grocery News,' Sept. 19; 'Produce Markets Review,' Sept. 19; 'Practical Magazine,' for September; 'Educational Times,' for September; 'British Journal of Dental Science,' for September; 'Journal of Applied Science,' for September; 'American Journal of Pharmacy,' for September; 'Pharmacist,' for September; 'Canadian Pharmaceutical Journal,' for September; 'Tennessee Pharmacal Journal,' for September; 'Moniteur Scientifique,' for September; 'Pharmaceutische Zeitung,' for Sept. 16 and 19; 'Sanitary Record,' Sept. 19.

LEAD IN AERATED WATERS.

BY J. C. HUNTER, A.P.S.

Poisoning accidentally by means of water impregnated with lead has occurred in the past, and it also occurs in the present time, from the same cause. An instance of this kind happened near Glasgow a short time ago.

An old lady died near Glasgow, and her medical attendant, Dr. Wilson, was rather perplexed to account for some of the symptoms that affected her; he was sure that they indicated lead poisoning, there being no source from whence the lead could be obtained and introduced into her system unless by means of soda-water, which she was in the habit of taking largely, sometimes as many as six bottles daily. Consequently he got Dr. Wallace, of Glasgow, to analyse a sample, and, as he suspected, lead was found to be present, which at once cleared up the mystery as to the symptoms that affected her.

After this case I was determined to see if this contamination was general, and from my own results and those of Dr. Milne, of Glasgow, it has been proved to be more general, at least in Glasgow, than one would suppose.

Having selected at random from our stock two bottles of soda-water and one bottle of lemonade, and having subjected them respectively to analysis, I found lead present in them all.

Its presence being proved, I now wished to know in what quantity it was present, and on quantitative analysis, it was proved to be present in the proportion of in—

Sample No. 1, Soda-water, 2-10ths grain per gallon.
„ „ 2, „ „ „

and in the sample of lemonade in the proportion of a quarter grain per gallon. These three samples were made by a well-known and long-established house in Glasgow.

Dr. Milne, of Glasgow, has confirmed the above results by independently analysing several samples bought around Glasgow.

He has found in soda-water the following amounts of lead:—

Sample 1. 2-10ths grain lead per gallon.
„ 2. 6-10 „ „ „
„ 3. 1-10 „ „ „

In lemonade he found it present as follows:—

Sample 1. 2-10ths grain per gallon
„ 2. 4-10 „ „

In gingerade nearly 1-20th grain per gallon.

Now, from the above results it is evident that aerated waters are sometimes contaminated more or less with lead, which lead is obtained from leaden cisterns, or pipes used in their manufacture; for on testing the Loch Katrine water, and also water from the other source which supplies the greater part of the south side of Glasgow, there was not the slightest indication of lead.

Water, aerated or otherwise, impregnated with lead, when taken into the system in small doses, which accumulate, is well known to be hurtful to health. Dr. Muspratt, in his 'Chemistry,' mentions a case that came under his notice where several families were affected with lead-poisoning, which was traced to the water; and, on the cistern being coated with slate slabs, and glazed iron pipes used to supply the water, the health of the families affected was completely restored.

From the foregoing results I would suggest that our public analysts throughout England and Scotland should investigate as to the presence or absence of lead in our aerated waters as supplied to the trade.

I think the proof of the presence of lead in those beverages, now so largely consumed in this country, would add more to the reputation of some of our analysts than the paltry catch analyses which some of them favour us with now and again, much to the detriment of trade. For I maintain that if we can get proof that lead exists in any proportion in our aerated waters, the makers of them are quite liable to be prosecuted under the Adulteration Act.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from p.* 222.)

Leaves.—The microscopical structure of leaves is often of great interest to the microscopist, and to the analyst, and will afford the means of accurate diagnosis when only fragments are present, as in the adulteration of tobacco; or when the leaves have been subjected to certain processes, as in the adulteration of tea. They require somewhat considerable manipulative skill for their complete examination, but a very little practice will enable the student to make sufficiently good preparations for analytical purposes. Frequently, indeed, little or no preparation at all is necessary.

The various tissues of leaves may be grouped as follows:—Vascular, cellular, epidermal.

The *Vascular* tissues form what are popularly known as the veins and ribs of the leaves. They differ in their arrangement much, and in their component parts somewhat, in different plants. Speaking generally, these tissues may be said to consist of spiral vessels composed of one, two, or more fibres, annular, netted or pitted vessels, associated in different proportions—sometimes all are present—and woody fibres. With the vascular tissues we must include the laticiferous systems, and perhaps the accompanying liber may best here find a place. These last differ greatly in different plants, especially as regards the numbers present. There may be either one or two sets of vascular tissues in the same leaf, an upper and a lower, when two are present.

The course of the vascular system within the leaves may be traced by the naked eye in most other than very fleshy leaves, and easily enough in skeletonized leaves, and often affords a ready means for determining between two leaves. The remarkable looped veins of tea-leaves, for instance, are quite unlike those of other leaves at all resembling them, or likely to be used as an adulterant. The vascular system may be studied microscopically in transverse sections of leaves, which show the cross sections of the vessels, their arrangement with regard to each other, and the amount of thickening the wood and other cells have received. The character of the vessels, whether spiral or otherwise, may be best made out when leaves, boiled either in water, alkali, or dilute acids, are teased out under a single microscope, the vessels removed and examined in glycerine, under a half-inch or a quarter-inch objective. They may be permanently mounted either in glycerine, glycerine jelly, or Canada balsam, the two former being preferable. They may be examined *in situ* in succulent leaves, if the cuticle be removed and a thin horizontal section be made of the cellular tissues.

The cellular tissues are not often of so much importance to the analyst as those of the cuticle, but they are often of considerable interest to the microscopist.

They differ much in different plants, but may be grouped into two, or perhaps three, classes of cells. We have first blunt-ended sub-cylindrical cells placed endwise, that is, vertical to the upper surface, beneath which they are, containing chlorophyll and other colouring matters and sometimes crystals; and secondly a loose parenchymatous tissue, very varied in character, often of erratic shape, and containing, with chlorophyll, starch. Frequently this inner layer is loosely adherent, sometimes large spaces occur, and, speaking generally, the whole tissue is characterized by want of firmness and strength. The special spiral or reticulated cells of some orchids, *Sanseviera*, and according to Schleiden, *Gesnera latifolia*, and the cells approaching the cubical underlying the vertical cells of the upper surface; and sometimes, also, the spongiform parenchyma, in certain plants, as species of *Ficus*, and also perhaps the cells forming the internal glands of Myrtaceæ and Rutaceæ, might all be classed into a third group of modified parenchyma cells, did not difficulties arise as to where the line should be drawn between the ordinary cellular, or the vascular, and these specialized tissues. The collenchymatous tissues of *Barosma* lately described by Professor Flückiger, must probably, as we shall see presently, be classed as a distinct class of cell from the two classes I have been speaking of, and will most likely be made into a third class by future writers.

The several details of structure, just referred to, may be studied in vertical sections immersed in water or glycerine. Such sections may easily be made by means of a razor, either with or without the section-cutting instrument. Much better sections, however, may be made by the aid of this instrument, and its use is almost essential when many successive sections are wanted with a view to tracing some particular tissue for a considerable distance. A fine soft cork should be chosen, of such size as will fit the tube of the section instrument. The cork should be slit, a slice the thickness of the leaf removed, and the leaf placed between its halves, and the whole placed in the instrument. When this plan is followed, the leaf is not injured by pressure, which in the case of succulent leaves seriously interferes with obtaining good sections. Cork and leaf are cut together by means of a sharp razor, and separated in water by means of a camel hair brush or needles. Horizontal sections of course cannot be cut in this way. A leaf may, however, be gummed on the level surface of a cork placed in the cutter, and several successive sections cut. Care must be taken that the upper and lower ends of the cork are exactly parallel, or the sections will not be perfectly horizontal, and wrong conclusions will be arrived at. The epidermis and cuticle must be removed from the subjacent tissues before they can be properly investigated. The lower cuticle may in most leaves be torn off by means of a pair of fine forceps, but more or less prolonged maceration is usually required before the upper can be removed in a sufficiently clean state. I have found the following plan answer well with nearly all leaves, more especially the tough leathery leaves that are so troublesome when dealt with in the ordinary way. I cut off the base of the leaf and one margin with a pair of scissors, boil the leaf for a minute or so in water, and then in liq. potassæ (B.P.) for several minutes (10 to 30). I pour off the alkali and fill the test tube with warm water, in which I agitate the leaves somewhat violently. Usually the cuticles separate from the parenchymatous tissues at once, and these latter are more or less completely dissolved in the warm water. The cuticles and vascular systems are removed and mounted in glycerine jelly for examination. This plan answers well for skeletonizing leaves, but the "skeletons" require to be bleached by chlorine or sulphurous acid gas to make them presentable.

The several points to be attended to, from a technical point of view, in the examination of cuticles are, the comparative size and shape of the cells of the upper and lower surface; the occurrence of stomates on one or both, their number per inch, shape, and composition, *i.e.*, of two or more cells. The amount of thickening of the upper surface (*i.e.*, the epidermis) is of importance, but only secondarily. The nature of the surface appendages, whether hairs, if so, simple or compound, unicellular or multicellular, scales or glands, is of considerable importance, and can be ascertained by simply viewing unprepared leaves by reflected light, and by removing the hairs, etc., when present, by scraping the surface of the leaf with a sharp scalpel. Sections and other preparations of leaves should always be mounted in glycerine, or other fluid, or in glycerine jelly. Cuticles *in situ*, intended for examination by reflected light, must of course be mounted dry.

Buchu Folia.* —In some respects these leaves possess the common features of the natural order to which they belong, but in some other respects they are nearly unique. They require careful study, and many points in their structure require much working at with the aid of careful micro-chemical and ordinary chemical (ultimate) analysis. Prof. Flückiger† divides the tissues of these leaves into three layers, neglecting the cells of the epidermis. So far the leaves of the three kinds of Buchu, *Barosma betulina*, *B. crenulata*, and *B. serratifolia* are agreed; they have minor differences, which I will presently indicate. The epidermis of the upper surface of the leaves is quite devoid of stomata, and is composed of five and six-sided irregularly-shaped cells, not sinuous, and covered externally with a thick layer of the ordinary cuticular substance, which here as elsewhere stains deeply with magenta. Near the margin of the leaves these cells are much elongated, and are also rather modified over the midrib, but to a much smaller extent than is usual. The vertical section of these cells is oblong, and they are frequently much compressed towards the margin of the leaf. Within these cells is the remarkable layer of cells described by Professor Flückiger. These are, when in their natural conditions, oval cells with their long axis perpendicular, and have very thin walls. They contain but little chlorophyll, in the form of minute granules, and charged with amorphous nearly soluble starch, but much mucilage, which appears to be identical with the mucilage of linseed and quince. If a section of the leaf be placed in an aqueous solution of chromic acid, this layer of cells is seen to swell up gradually with a distinct striation parallel to the surface of the

* See also Prof. Flückiger's paper in Sch. Wochensch. für Pharm. reprinted (without plates,) in Pharmaceutical Journal (3), vol. iv., p. 689. I am indebted to Professor Flückiger for a reprint of the original memoir.

† Op. cit.

leaf, and a less distinct striation vertical thereto, and determined by the walls of the containing cells. In water the swelling is more rapid, but the striation is not so evident. The swelling continues until the epidermis is forced off, often the inner membrane of the epidermal cell is much torn, and the whole of the mucilage-bearing layer is broken up, and the mucilage dissolved in the water. The cell-walls themselves do not, I think, dissolve; they simply become broken up and invisible on account of the close identity of their refractive index with that of the mucilaginous solution. They may be seen floating in small pieces, if the section be previously carefully stained with tincture of iodine, and their reaction throughout is that of pure cellulose. The mucilage itself does not stain with iodine, nor does it give any cellulose reaction. Its reactions, so far as I have been able to study them, are those of a mucilage contaminated with chlorophylloids, and with other protein matters.

The same swelling occurs in a smaller degree and less rapidly when glycerine is used; essential oils and alcohol have no effect. This layer exists in the three species of *Barosma*, but is perhaps most highly developed, in proportion to the thinness of the leaf, in the thinner leaved species, as the size of the collenchyma cells remains pretty constant through the genus, but varies slightly with the age of the leaf; or perhaps it will be more accurate to say that the mucilaginous contents are more highly developed in the mature than in the young or very old leaves.

Beneath these cells are layers of very small irregularly shaped chlorophyll-bearing cells in which the small veins of the leaf terminate in a remarkable club-shaped expansion. The cells themselves are not remarkable, except on account of their numerous sphæraphides of oxalate of lime, but the nerve-vein terminals are worth much more attention than any one appears yet to have given them,* and there is little doubt in my mind that they will prove to be absorbent organs of some kind. They are in many respects similar to the "organs" figured some years since by Mr. Herbert Spencer, and found in the roots of certain plants. Beneath this layer we have the loose spongy or stellate parenchyma of the interior of the leaf and the overlying vascular system. There is nothing at all remarkable in the loose parenchyma. The vascular system is very largely developed, and, as I have just said, is remarkable for the full development of its terminals in the chlorophyll-bearing tissues. The wood-fibres accompanying it are very long, tough, and cord-like. In this tissue are also the remarkably large oil reservoirs so commonly found in the plants of this and a few other natural orders. They are well formed, with several layers of specialized cells, and contain, no doubt, with other matters, the aromatic oil examined by Professor Flückiger. The lower epidermis lies beneath these, and is remarkable for the great number of two-celled stomata, which are evenly disposed over its surface, except where the oil-glands determine a locally modified arrangement. The cells of this epidermis resemble those of the upper except in size, but are subject to more frequent modifications (*a*) by the stomates, (*b*) by the midrib, and (*c*) most characteristically by the subjacent oil-glands. Above these the cuticle cells are much changed as regards shape, and group themselves in irregular circles, with the gland-cell over it as a focus.

Sections of these leaves, immersed in an alcohol solution of magenta, much diluted with water, form very interesting objects, and much facilitate the working out of many of these details.

(*To be continued.*)

* This is by no means the only leaf in which they occur, they are, however, more highly developed here than elsewhere.

NOTE ON SCAMMONY.*

BY THOMAS GREENISH, F.C.S.

The result of a microscopic examination of different samples of virgin scammony may at the present time possess some interest, and if it gives rise to a discussion, some remarks may be elicited possessing more intrinsic value than the paper itself.

I was induced to undertake this subject from having observed that the presence of starch was usually detected by iodine, and that little attention had been given to determine the particular kind of starch granules, whether of wheat, or those peculiar to the scammony root itself.

The scammony which appears in English commerce is principally of four kinds—virgin scammony, Angora scammony, Syrian scammony, and Skeleep scammony.

Of the virgin scammony not more than 800 lbs. arrives in this country yearly, none of which is again exported. Of the Angora and Syrian scammonies about half a ton each are annually imported. Of this quantity half remains in this country. Of the Skeleep scammony about one ton annually arrives in London, only half of which is again exported.

The Angora and Syrian scammonies vary in amount of resin from 46 to 76 per cent., while the Skeleep contains about 36 per cent. only, the remainder being impurity.

We have thus one ton of adulterated scammony remaining in this country every year. According to Mr. Maltass, the peasants adulterate scammony before bringing it into the market, the adulterations being wheat, starch, wood, ashes, earth, gum arabic or tragacanth, pounded scammony roots, etc.

The starch granules peculiar to the scammony root are shown in this diagram; they are, for the most part,

compound, composed of two, three, and sometimes more granules. In shape the single granules resemble those of Tacca, muller-shaped, with dihedral base, and the hilum approximates to that seen in the starch of orris-root. With polarized light the arms of the black cross run down in the direction of those lines marked on the grains. Occa-

* Read before the British Pharmaceutical Conference, August 7, 1874. The discussion to which the reading of the paper gave rise has been reported, *ante*, p. 191.

sionally a lenticular grain is met with, but the hilum or markings about the hilum serve to distinguish it from that of wheat starch, to which it otherwise bears a close resemblance.

The starch grains from the scammony root vary very much in size about the centre of the root, where the texture is loose; some granules will be found very large, at the same time in company with these will be found a good many of very variable size.

From an examination of a variety of samples of virgin scammony from different sources, I may state as a result, that the *lump* was in every instance free from the starch of scammony root or any other starch, and that every sample of *powdered* virgin scammony contained more or less of the scammony starch, and some of them a little wheat starch in addition. A few also contained particles of the tissue peculiar to the root with the starch grains still in it, and I would observe that the examinations here referred to were made on the finest samples of virgin scammony.

In these investigations I think it very desirable, having determined the presence of starch, to distinguish the granules of the scammony starch from those of wheat. I consider that the presence of the scammony starch indicates an admixture of inferior scammony, and more especially when it is accompanied by some of the tissue of the root. There exists a theory to account for the wheat starch, that it is used to prevent the semi-solid gum resin from sticking to the hands. If this were correct, I should expect to find it *especially* in that powder which adheres to the outside of the lumps of scammony, constituting what may be termed the bloom upon it; but I do not find this to be the case in the samples which I have examined, neither does the greyish white powder which covers the lump consist, so far as I have observed, of chalk. It seems to me to be merely the particles of scammony reduced to a powder by the friction of the lumps against each other, and it is of the same quality in every respect as the lump from which it has been detached.

I can only account for the presence of starch in powdered virgin scammony, by reference to the practice of picking the virgin scammony in lump from the chest, and suggesting that after a good deal of picking there must remain a quantity of fragments, too small for further picking, but not for grinding. To this must be added the fact, that sometimes in a chest a good piece of virgin scammony may have a very inferior one stuck to it, so as to escape observation. It is much to be desired that flour and starch, when spoken of in connection with scammony, should not be considered synonymous. I have never met with cellular tissue, such as I should expect to find if flour had been present.

It is an interesting question, whether the gum resin possesses any value over the more uniform and less costly resin obtained from the dry root. If it should prove that the resin is equally active and more reliable than the exuded gum resin, then the pharmacist would be independent of the Greek of the Levant, or the Turk nearer home.

I have examined the mineral matter scraped from the outside of a fine specimen of the root, and find it to be, as already shown by Professor Attfield, a calcareous earth, which effervesces with hydrochloric acid, indicating that it was grown on a chalky soil.

THE CARNIVOROUS HABITS OF SOME PLANTS.*

BY DR. HOOKER, C.B., D.C.L., PRES. R.S.

(*Concluded from p.* 248.)

But to return from mere conjecture to scientific earnest, I cannot dismiss *Darlingtonia* without pointing out to you what appears to me a most curious point in its history; which is, that the change from the slender, tubular, open-mouthed, to the inflated, closed-mouthed pitchers, is, in all the specimens which I have examined, absolutely sudden in the individual plant. I find no pitchers in an intermediate stage of development. This, a matter of no little significance in itself, derives additional interest from the fact that the young pitchers to a certain degree represent those of the *Sarracenias* with open mouths and erect lids; and the old pitchers those of the *Sarracenias* with closed mouths and globose lids. The combination of representative characters in an outlying species of a small order cannot but be regarded as a marvellously significant fact in the view of those morphologists who hold the doctrine of evolution.

Nepenthes.—The genus *Nepenthes* consists of upwards of 30 species of climbing, half-shrubby plants, natives of the hotter parts of the Asiatic Archipelago from Borneo to Ceylon, with a few outlying species in New Caledonia, in Tropical Australia, and in the Seychelle Islands on the African Coast. Its pitchers are abundantly produced, especially during the younger state of the plants. They present very considerable modifications of form and external structure, and vary greatly in size, from little more than an inch to almost a foot in length; one species, indeed, which I have here from the mountains of Borneo, has pitchers which, including the lid, measure a foot and a half, and its capacious bowl is large enough to drown a small animal or bird.

The structure of the pitcher of *Nepenthes* is less complicated on the whole than that of *Sarracenia*, though some of its tissues are much more highly specialized. The pitcher itself is here not a transformed leaf, as in *Sarracenia*, nor is it a transformed leaf-blade, like that of *Dionœa*, but an appendage of the leaf developed at its tip, and answers to a water-secreting gland that may be seen terminating the mid-rib of the leaf of certain plants. It is furnished with a stalk, often a very long one, which, in the case of pitchers formed on leaves high up the stem, has (before the full development of the pitcher) the power of twisting like a tendril round neighbouring objects, and thus aiding the plant in climbing, often to a great height, in the forest.

In most species the pitchers are of two forms, one appertaining to the young, the other to the old state of the plant, the transition from one form to the other being gradual. Those of the young state are shorter and more inflated; they have broad fringed longitudinal wings on the outside, which are probably guides to lead insects to the mouth; the lid is smaller and more open, and the whole interior surface is covered with secreting glands. Being formed near the root of the plant, these pitchers often rest on the ground, and in species which do not form leaves near the root they are sometimes suspended from stalks which may be fully a yard long, and which bring them to the ground. In the older state of the plant the pitchers are usually much longer, narrower, and less inflated, trumpet-shaped, or even, and are conical; the wings also are narrower, less fringed, or almost absent. The lid is larger and slants over the mouth, and only the lower part of the pitcher is covered with secreting glands, the upper part presenting a tissue analogous to the conducting tissue of *Sarracenia*, but very different anatomically. The difference in structure of these two forms of pitcher, if considered in reference to their different positions on the plant, forces the conclusion on the mind, that the one form is intended for ground game, the other for winged game. In all cases the mouth of the pitcher is furnished with a thickened corrugated rim, which serves three purposes: it strengthens the mouth and keeps it distended; it secretes honey (at least in all the species I have examined under cultivation, for I do not find that any other observer has noticed the secretion of honey by *Nepenthes*), and it is in various species developed into a funnel-shaped tube, that descends into the pitcher, and prevents the escape of insects, or into a row of incurved hooks, that are in some cases strong enough to retain a small bird, should it, when in search of water or insects, thrust its body beyond a certain length into the pitcher.

* Address to the department of Zoology and Botany of the British Association.

In the interior of the pitcher of *Nepenthes* there are three principal surfaces; an *attractive*, *conductive*, and a *secretive* surface; the *detentive* surface of *Sarracenia* being represented by the fluid secretion, which is here invariably present at all stages of growth of the pitcher.

The attractive surfaces of *Nepenthes* are two: those, namely, of the rim of the pitcher, and of the under surface of the lid, which is provided in almost every species with honey-secreting glands, often in great abundance. These glands consist of spherical masses of cells, each embedded in a cavity of the tissue of the lid, and encircled by a guard-ring of glass-like cellular tissue. As in *Sarracenia* the lid and mouth of the pitcher are more highly coloured than any other part, with the view of attracting insects to their honey. It is a singular fact that the only species known to me that wants these honey glands on the lid is the *N. ampullaria*, whose lid, unlike that of the other species, is thrown back horizontally. The secretion of honey on a lid so placed would tend to lure insects away from the pitcher instead of into it.

From the mouth to a variable distance down the pitcher is an opaque glaucous surface, precisely resembling in colour and appearance the conductive surface of the *Sarracenia*, and, like it, affording no foothold to insects, but otherwise wholly different; it is formed of a fine network of cells, covered with a glass-like cuticle, and studded with minute reniform transverse excrescences.

The rest of the pitcher is entirely occupied with the secretive surface, which consist of a cellular floor crowded with spherical glands in inconceivable numbers. Each gland precisely resembles a honey-gland of the lid, and is contained in a pocket of the same nature, but semicircular, with the mouth downwards, so that the secretive fluid all falls to the bottom of the pitcher. In the *Nepenthes Rafflesiana* three thousand of the glands occur on a square inch of the inner surface of the pitcher, and upwards of a million in an ordinary sized pitcher. I have ascertained that, as was indeed to be expected, they secrete the fluid which is contained in the bottom of the pitcher before this opens, and that the fluid is always acid.

The fluid, though invariably present, occupies a comparatively small portion of the glandular surface of the pitcher, and is collected before the lid opens. When the fluid is emptied out of a fully formed pitcher that has not received animal matter, it forms again, but in comparatively very small quantities; and the formation goes on for many days, and to some extent even after the pitcher has been removed from the plant. I do not find that placing inorganic substances in the fluid causes an increased secretion, but I have twice observed a considerable increase of fluid in pitchers after putting animal matter in the fluid.

To test the digestive powers of *Nepenthes* I have closely followed Mr. Darwin's treatment of *Dionæa* and *Drosera*, employing white of egg, raw meat, fibrine, and cartilage. In all cases the action is most evident, in some surprising. After twenty-four hours' immersion the edges of the cubes of white of egg are eaten away and the surfaces gelatinized. Fragments of meat are rapidly reduced; and pieces of fibrine weighing several grains dissolve and totally disappear in two or three days. With cartilage the action is most remarkable of all; lumps of this weighing eight and ten grains are half gelatinized in twenty-four hours, and in three days the whole mass is greatly diminished, and reduced to a clear transparent jelly. After drying some cartilage in the open air for a week, and placing it in an unopened but fully formed pitcher of *N. Rafflesiana*, it was acted upon similarly, and very little slower.

That this process, which is comparable to digestion, is not wholly due to the fluid first secreted by the glands, appears to me most probable; for I find that very little action takes place in any of the substances placed in the fluid drawn from pitchers, and put into glass tubes; nor has any followed after six days' immersion of cartilage or fibrine in pitchers of *N. ampullaria* placed in a cold room, whilst on transferring the cartilage from the pitcher of *N. ampullaria* in the cold room to one of *Rafflesiana* in the stove, it was immediately acted upon. Comparing the action of fibrine, meat, and cartilage placed in tubes of *Nepenthes* fluid, with others in tubes of distilled water, I observed that their disintegration is three times more rapid in the fluid; but this disintegration is wholly different from that effected by immersion in the fluid of the pitcher of a living plant.

In the case of small portions of meat, ½ to 2 grains, all seem to be absorbed; but with 8 to 10 grains of cartilage it is not so; a certain portion disappears, the rest remains as a transparent jelly, and finally becomes putrid, but not till after many days. Insects appear to be acted upon somewhat differently, for after several days' immersion of a large piece of cartilage, I found that a good-sized cockroach, which had followed the cartilage and was drowned for its temerity, in two days became putrid. In removing the cockroach the cartilage remained inodorous for many days. In this case, no doubt, the antiseptic fluid had permeated the tissue of the cartilage, whilst enough did not remain to penetrate the chitinous hard covering of the insect, which consequently decomposed.

In the case of cartilage placed in fluid taken from the pitcher, it becomes putrid, but not so soon as if placed in distilled water.

From the above observations it would appear probable that a substance acting as pepsine is given off from the inner wall of the pitcher, but chiefly after placing animal matter in the acid fluid; but whether this active agent flows from the glands or from the cellular tissue in which they are imbedded, I have no evidence to show.

I have here not alluded to the action of these animal matters in the cells of the glands, which is, as has been observed by Mr. Darwin in *Drosera*, to bring about remarkable changes in their protoplasm, ending in their discoloration. Not only is there aggregation of the protoplasm in the gland-cells, but the walls of the cells themselves become discoloured, and the glandular surface of the pitcher, that at first was of a uniform green, becomes covered with innumerable brown specks (which are the discoloured glands). After the function of the glands is exhausted, the fluid evaporates, and the pitcher slowly withers.

At this stage I am obliged to leave this interesting investigation. That *Nepenthes* possesses a true digestive process such as has been proved in the case of *Drosera*, *Dionæa*, and *Pinguicula* cannot be doubted. This process, however, takes place in a fluid which deprives us of the power of following it further by direct observation. We cannot here witness the pouring out of the digestive fluid; we must assume its presence and nature from the behaviour of the animal matter placed in the fluid in the pitcher. From certain characters of the cellular tissues of the interior walls of the pitcher, I am disposed to think that it takes little part in the processes of either digestion or assimilation, and that these, as well as the pouring out of the acid fluid, are all functions of the glands.

In what I have said I have described the most striking instances of plants which seem to invert the order of nature, and to draw their nutriment—in part at least—from the animal kingdom, which is often held to be the function of the vegetable kingdom to sustain.

I might have added some additional cases to those I have already dwelt upon. Probably, too, there are others still unknown to science, or whose habits have not yet been detected. Delpino, for example, has suggested that a plant, first described by myself in the 'Botany of the Antarctic Voyage,' *Caltha dionææfolia*, is so analogous in the structure of its leaves to *Dionæa*, that it is difficult to resist the conviction that its structure also is adapted for the capture of small insects.

But the problem that forces itself upon our attention is, how does it come to pass that these singular aberrations from the otherwise uniform order of vegetable nutrition make their appearance in remote parts of the vegetable kingdom? why are they not more frequent, and how were such extraordinary habits brought about or contracted? At first sight the perplexity is not diminished by considering—as we may do for a moment—the nature of ordinary vegetable nutrition. Vegetation, as we see it everywhere, is distinguished by its green colour, which we know depends on a peculiar substance called chlorophyll; a substance which has the singular property of attracting to itself the carbonic acid gas which is present in minute quantities in the atmosphere, of partly decomposing it, so far as to set free a portion of its oxygen, and of recombining it with the elements of water, to form those substances, such as starch, cellulose, and sugar, out of which the framework of the plant is constructed.

But, besides these processes, the roots take up certain matters from the soil. Nitrogen forms nearly four-fifths of the air we breathe, yet plants can possess themselves of none of it in the free uncombined state. They withdraw nitrates and salts of ammonia in minute quantities from the ground, and from these they build up with starch, or some analogous material, albuminoids or protein compounds, necessary for the sustentation and growth of protoplasm.

At first sight nothing can be more unlike this than a *Dionœa* or a *Nepenthes* capturing insects, pouring out a digestive fluid upon them, and absorbing the albuminoids of the animal, in a form probably directly capable of appropriation for their own nutrition. Yet there is something not altogether wanting in analogy in the case of the most regularly constituted plants. The seed of the castor-oil plant contains, besides the embryo seedling, a mass of cellular tissue or endosperm filled with highly nutritive substances. The seedling lies between masses of this, and is in contact with it—and has the warmth and moisture of germination set up, changes which bring about the liquefaction of the contents of the endosperm and the embryo absorbs them; it grows in so doing, and at last having taken up all it can from the exhausted endosperm, develops chlorophyll in its cotyledons under the influence of light, and relies on its own resources.

A large number of plants, then, in their young condition borrow their nutritive compounds ready prepared, and this is in effect what carnivorous plants do later in life.

That this is not merely a fanciful way of regarding the relation of the embryo to the endosperm, is proved by the ingenious experiments of Van Jieghem, who has succeeded in substituting for the real, an artificial endosperm, consisting of appropriate nutritive matters. Except that the embryo has its food given to it in a manner which needs no digestion—a proper concession to its infantine state—the analogy here with the mature plants which feed on organic food seems to be complete.

But we are beginning also to recognize the fact that there are a large number of flowering-plants that pass through their lives without ever doing a stroke of the work that green plants do. These have been called *Saprophytes*. *Monotropa*, the curious bird's nest orchid (*Neottia Nidus-avis*), *Epipogium*, and *Corallorhiza* are instances of British plants which nourish themselves by absorbing the partially decomposed materials of other plants, in the shady or marshy places which they inhabit. They reconstitute these products of organic decomposition, and build them up once more into an organism. It is curious to notice, however, that the tissues of *Neottia* still contain chlorophyll in a nascent though useless state, and that if a plant of it be immersed in boiling water, the characterestic green colour reveals itself.

Epipogium and *Corallorhiza* have lost their proper absorbent organs; they are destitute of roots, and take in their food by the surfaces of their underground stem structures.

The absolute difference between plants which absorb and nourish themselves by the products of the decomposition of plant-structures, and those which make a similar use of animal structures, is not very great. We may imagine that plants accidentally permitted the accumulation of insects in some parts of their structure, and the practice became developed because it was found to be useful. It was long ago suggested that the receptacle formed by the connate leaves of *Dipsacus* might be an incipient organ of this kind; and though no insectivorous habit has ever been brought home to that plant, the theory is not improbable.

Linnæus, and more lately Baillon, have shown how a pitcher of *Sarracenia* may be regarded as a modification of a leaf of the *Nymphæa* type. We may imagine such a leaf first becoming hollow, and allowing *débris* of different kinds to accumulate; these would decompose, and a solution would be produced, some of the constituents of which would diffuse themselves into the subjacent plant tissues. This is in point of fact absorption, and we may suppose that in the first instance—as, perhaps, still in *Sarracenia purpurea*—the matter absorbed was merely the saline nutritive products of decomposition, such as ammoniacal salts. The act of digestion—that process by which soluble food is reduced without decomposition to a soluble form fitted for absorption—was doubtless subsequently required.

The secretion, however, of fluids by plants, is not an unusual phenomenon. In many aroids a small gland at the apex of the leaves secretes fluid, often in considerable quantities, and the pitcher of *Nepenthes* is, as I have shown elsewhere, only a gland of this kind, enormously developed. May not, therefore, the wonderful pitchers and carnivorous habit of *Nepenthes* have both originated by natural selection out of one such honey-secreting gland as we still find developed near that part of the pitcher which represents the tip of the leaf? We may suppose insects to have been entangled in the viscid secretion of such a gland, and to have perished there, being acted upon by those acid secretions that abound in these and most other plants. The subsequent differentiation of the secreting organs of the pitcher into aqueous, saccharine, and acid, would follow *pari passu* with the evolution of the pitcher itself, according to those mysterious laws which result in the correlation of organs and functions throughout the kingdom of Nature; and which, in my apprehension, transcend in wonder and interest those of evolution and the origin of species.

Delpino has recorded the fact that the spathe of *Alocasia* secretes an acid fluid which destroys the slugs that visit it, and which he believes subserves its fertilization. Here any process of nutrition can only be purely secondary. But the fluids of plants are in the great majority of cases acid, and, when exuded, would be almost certain to bring about some solution in substances with which they came in contact. Thus, the acid secretions of roots were found by Sachs to corrode polished marble surfaces with which they came in contact, and thus to favour the absorption of mineral matter.

The solution of albuminoid substances requires, however, besides a suitable acid, the presence of some other albuminoid substance analogous to pepsine. Such substances, however, are frequent in plants. Besides the well-known diastase, which converts the starch of malt into sugar, there are other instances in the synaptase which determines the formation of hydrocyanic acid from emulsions, and the myrosin which similarly induces the formation of oil of mustard. We need not wonder, then, if the fluid secreted by a plant should prove to possess the ingredients necessary for the digestion of insoluble animal matters.

These remarks will, I hope, lead you to see that though the processes of plant nutrition are in general extremely different from those of animal nutrition, and involve very simple compounds, yet that the protoplasm of plants is not absolutely prohibited from availing itself of food, such as that by which the protoplasm of animals is nourished; under which point of view these phenomena of carnivorous plants will find their place, as one more link in the continuity of nature.

EVAPORATION AND DIFFUSION.*

BY PROFESSOR ODLING, M.A., F.R.S.

Of the circumstances on which the rate of evaporation of the same volatile substance chiefly depends, one very influential circumstance, namely, the nature of the atmosphere into which the vapour proceeds and distributes itself, does not appear to have been made the subject of careful examination. There is, however, one familiar experiment on the subject; and it consists in passing up a little ether into two equal volumes, one of hydrogen and the other of air, contained in similar cylinders standing over water. Evaporation of the ether takes place in both cases; though far more rapidly into the hydrogen than into the air, as shown by the far more rapid expansion of the hydrogenous than of the aerial space, from the addition to it of the ether-vapour. This experiment is usually cited in illustration of the greater rapidity at which ether-vapour diffuses itself into an atmosphere of light hydrogen than into an atmosphere of comparatively heavy air. It is doubtful, however, whether the explanation in this precise form is strictly correct, the diffusive mobility of any gas or vapour being a property altogether special to itself, irrespective of extraneous conditions. Thus, in a particular experiment, Mr. Graham found that while the quantity of hydrogen which in one minute of time passed through a graphite plate into a vacuum was 1·289 c. c., the quantity of hydrogen which in the same time passed through the same graphite plate into the surrounding air was 1·243 c. c., or almost exactly the same.

A novel experiment on the influence due to the nature of the contiguous atmosphere upon the rapidity of the process of evaporation consists in introducing into each of two similar tall cylinder bottles a sealed glass bulb containing a little iodine. The one cylinder being filled with hydrogen, and the other with air, and each having suspended from its mouth a piece of starched paper or cloth, the bulbs are then broken by concussion of the containing cylinders. But, in this case, the test paper or cloth suspended in the cylinder of air becomes affected by the iodine considerably before that suspended in the cylinder of hydrogen; or, contrary to what happens with ether, the iodine *appears* to volatilize more quickly in the comparatively heavy air than in the much lighter hydrogen. Similarly, if some weak aqueous ammonia contained in a sealed glass bulb be set free in a tall bottle of hydrogen, and also in a tall bottle of air, a piece of turmeric paper suspended from the stopper of each bottle becomes affected by the ammonia vapour more quickly in the bottle of air than in the bottle of hydrogen.

Water may be taken as the type of a volatile substance, and the nature of the process of evaporation be conveniently studied in relation thereto. Now, in a hermetically-closed vessel exhausted of air, but partly filled with water, the matter of the water exists in two states—a portion of it in the liquid state, and another portion in the aerial, or vaporous, or evaporated state; and, with excess of liquid water present, the quantity of vaporous water that can exist in an otherwise vacuous space, or the density of the vapour filling the space, is found to vary solely with the temperature. Thus 100 cubic inches of space will contain, at 58° C., 3 grains of vaporous water; at 100° C., 15 grains; at 144° C., 58 grains, and so on; or the densities of the vapour of water at these different temperatures are as the numbers 3, 15, and 58 respectively. Now, the quantity of water-vapour that can exist at any particular temperature in a volume of otherwise vacuous space is almost identical—it used to be considered absolutely identical,—with the quantity of vapour that can exist in the same volume of space already occupied by air. In other words, a cubic inch of water-vapour, and a cubic inch of air saturated with water-vapour, contain the same weight of the matter of water. Hence it is found that with continuous increase of temperature, a greater and greater quantity of liquid water ceases to be liquid and becomes vaporous, or is, in other words, evaporated into the adjoining space, whether vacuous or aerial; and conversely with decrease of temperature, a greater and greater quantity of vaporous water ceases to be vaporous, and is deposited in the liquid state. Thus, upon cooling a globe of transparent warm moist air, it is at once filled with an opaque mist, which, left to itself, soon becomes deposited in the form of drops; but which may be readily made to disappear or re-vaporize by gently heating the globe. The deposition of dew on cold surfaces brought into a warm moist room is familiar to all.

The tension or spring of water-vapour varies with the quantity of vapour filling the space—that is, with the density of the vapour, and consequently with its temperature. Thus the tension is equal, at 15° C., to a pressure of 13 millimetres of mercury; at 60° C., to a pressure of 149 millimetres; at 100° C., to a pressure of 760 millimetres; at 144° C., to a pressure of 3,040 millimetres. At the temperature of 100° C., the tension of the vapour of water being equal to a pressure of 760 millimetres of mercury, balances the tension or pressure of the atmosphere, as measured by the height of the barometric column. Hence, on continuing to heat water already at the temperature of 100°, it boils, or is converted into vapour, having a tension equal to that of the atmosphere. And so with a less or greater external pressure, water boils at a lower or higher temperature—in each case at the particular temperature whereat the elastic force of the water-vapour balances the particular external pressure. Under a pressure of 149 millimetres, for instance, water boils at 60° C.; under a pressure of 3040 millimetres, it boils at 144° C. The occurrence, then, of ebullition at some particular point of temperature may be viewed as a mere accident of the process of evaporation—a more and more rapid evaporation, with production of vapour of higher and higher density and elasticity, proceeding continuously with the continuous increase of temperature, although, indeed, at a far more rapid rate than the rate of increase of temperature.

In the conversion of liquid water into water-vapour heat is absorbed. It was at one time considered that the quantity of heat absorbed was independent of the temperature and correlative tension of the vapour yielded, and that it varied only with the quantity yielded. It was held, for example, that in the conversion, say, of a gramme of liquid water into a gramme of water-vapour—whether of tenuous vapour at a low temperature, or of dense vapour at a high temperature—the same quantity of heat was absorbed. This rule, though now known to be only approximately true, is nevertheless sufficiently true to allow of the amount of cold or absorption of heat resulting from any evaporation being taken as an indication or measure of the amount of that evaporation. The depression of temperature caused by the evaporation of water is familiarly shown in the use of the wet-bulb hygrometer. This instrument, consisting simply of a couple of thermometers, one of which has its bulb kept continuously moist, the difference in way of deficit between the temperature manifested by this wet-bulb thermometer and the temperature manifested by the other thermometer, is a measure of the amount of water evaporating from the surface of the moistened bulb.

What is true of liquid water and of water-vapour is true, in principle, of other volatile liquids and of their several vapours. At any given temperature some of these bodies volatilize much more rapidly, others of them much less rapidly, than one another, and than water; and in the process of their evaporation some of them absorb a much greater amount of heat than others, though for the same weight of vapour formed no one of them is known to absorb so large an amount of heat as water. Disulphide of carbon, ether, and alcohol are familiar examples of bodies more volatile than water; aniline, mercury, and molten silver, of bodies less volatile. It is well known

* Lecture delivered at the Royal Institution of Great Britain.—Reprinted from the proceedings.

that water when required pure is distilled—that is to say, it is first vaporized by heat and then re-liquefied by cold; and silver when required absolutely pure is sometimes submitted to the same process of distillation. Evaporation is, moreover, a property not only of liquid, but also of solid bodies, as of sal-ammoniac, iodine, camphor, ice and snow, solid carbonic acid, etc. Many of the phenomena of evaporation can be illustrated more conveniently with other volatile substances than with water. Thus the cooling produced by evaporation may be strikingly illustrated by means of ether, and still more strikingly by means of some liquefied gas, as liquefied sulphurous or nitrous oxide.

The necessary influence of some conditions on the rate of evaporation is obvious. Evaporation being a direct result of the absorption of heat, and the higher the temperature the greater the quantity of vapour capable of existing in a given space, it is found that at higher and higher temperatures water evaporates or dries up more and more rapidly, in proportion approximately to the increasing density of the vapour at higher and higher temperatures. Wet linen, for example, is habitually dried by being hung before the fire or placed in heated chambers or ovens.

Similarly, with regard to the influence of the extent of liquid surface on the rate of evaporation, it is found that the evaporation of a given weight of liquid water takes place more rapidly when the water is spread out in a wide dish than when it is contained in a narrow tube, in proportion to the greater extent of surface from which the evaporation can take place in the one case than in the other. Thus, while half a pint of water in a tumbler will remain for an almost indefinite time without becoming dried up, half a pint of water absorbed in a thick towel, exposing on its two sides more than a dozen square feet of surface, will become dried up in the course of twenty-four hours.

Again, the influence exerted by the greater or lesser dryness of the adjacent space, whether or not aerial, upon the evaporation of water is obvious. Into a space already saturated with vapour no further evaporation whatever can take place; and other conditions being alike, the drier the space the greater the amount of evaporation that can take place with it, and the more rapid the process of evaporation. In the laboratory moist substances are made dry by allowing the water from them to evaporate into spaces kept artificially dry by means of desiccating agents, such as oil of vitriol, quicklime, chloride of calcium, etc., which absorb the water-vapour from the space as fast as it is produced therein. Moreover, evaporation proceeding into any space, vacuous or aerial, until the space is saturated with water-vapour, and more rapidly in proportion to the removal from saturation of the space, it is obvious that, other conditions being equal, evaporation proceeds more rapidly into a large space requiring for its saturation a considerable weight of water-vapour than into a small space capable of being saturated by a minute quantity of the vapour.

The influence of the extent of aerial space into which a vapour can distribute itself upon the rate of formation of the vapour leads to a consideration of the effect of the movement of the contiguous air upon the rate of evaporation from a given surface. With an absolutely quiescent atmosphere, the layer of atmosphere in immediate contact with the surface of evaporating liquid must become quickly saturated with vapour; and but for some spontaneous means of removal of the vapour itself, or the air saturated with it, from the surface of the liquid, all further evaporation would be arrested. The nature of these spontaneous means of removal will be considered presently; but the influence of the artificial removal of the more or less saturated air from the surface of the evaporating liquid can be easily manifested. Thus, on allowing a strong current of air to play upon a surface of ether contained in a thin glass vessel standing on a stratum of water, the stratum of water becomes quickly frozen by reason of the heat abstracted from it, in the rapid production of ether-vapour which takes place in the current of air. For whereas with the ether in the vessel left to itself, the interior of the vessel soon becomes saturated with ether-vapour, and further evaporation with correlative cooling effect is almost arrested, with a current of air blown on to the surface of the ether, the liquid ether is in continuous contact with a fresh unsaturated atmosphere, into which it continues to evaporate with rapidity.

In connection with the above influences, it is observable that the evaporation of water from growing plants is favoured by the three conditions of extent of leaf surface, movement of the more or less dry atmosphere, and heat of the summer sun. An early and very striking experiment on the extent of this evaporation was made by Dr. Stephen Hales in 1724, and is recorded in his 'Vegetable Statics.' He found that with a healthy, full-grown sunflower more than a yard high, planted when young in a suitable pot, the evaporation from the plant itself amounted on the average to 20 ounces in a twelve hours' day, the maximum quantity being 30 ounces. Some very interesting and exact modern experiments on this subject were conducted in 1850 by Mr. Lawes, at Rothamstead. As an example of the results obtained, he found that a plant of barley, during a period of 172 days' growth, in which it acquired 419 grains of dry organic, and 46 grains of dry mineral matter, evaporated not less than 120,000 grains, or upwards of 17lbs. of water; so that for every grain of dry matter, organic and mineral, fixed by the plant during its period of growth, 257 grains of water were absorbed and evaporated.

A most important condition affecting the rate of evaporation is the pressure on the surface of the volatile substance. Into a vacuum indeed, where there is no pressure, evaporation is practically instantaneous. Thus, on letting up a little water, alcohol, or ether into the vacuum of a barometer, the mercury is at once depressed to the maximum extent producible by the tension of the particular vapour at the particular temperature. Again, on breaking a sealed bulb of iodine, within and at the lower end of a long sealed vacuous tube, a piece of starch-paper at the upper end of the tube is almost immediately affected by the iodine vapour. Further, the cooling consequent on the rapid evaporation of ether, ammonia, etc., into a vacuum, is taken advantage of in the construction of several well-known freezing machines. Again, in Leslie's celebrated experiment, the evaporation even of water into a vacuous space, from which the water-vapour is removed by some desiccant as fast as produced, takes place with such rapidity and correlative absorption of heat as to effect the freezing of the residual water from which the evaporation is proceeding. The same result is effected in Wollaston's cryophorus, the water-vapour in this case not being absorbed by oil of vitriol or other desiccant, but being simply condensed by cold applied to the other and distant bulb of the twice bent vacuous tube. Moreover, it was long ago shown by Daniel that evaporation of water into the same dry atmosphere takes place at a rate inversely proportioned to the pressure of the atmosphere. Thus in a particular set of experiments, the pressures of the air being 30·4, 15·2, and 7·6 inches of mercury, the quantities of water evaporated in half an hour were found to be 1·24, 2·97, and 5·68 grains respectively.

That the nature of the atmosphere into which a vapour can distribute itself has an important influence on the rate of formation of the vapour may be manifested by several experiments, in addition to those shown at the beginning of the lecture. Thus, with a couple of thin glasses standing on a stratum of water, and containing each some rectified wood-spirit, if the one portion of spirit be blown upon by a strong current of hydrogen, and the other portion by a strong current of air, the stratum of water underlying the glass of spirit blown upon by the hydrogen will alone become frozen, by reason of the excessive vaporization of, and heat-absorption by, the spirit in contact with the atmosphere of hydrogen. Again, a series of experiments has recently been made by the speaker on the relative rates of evaporation of water into limited atmospheres of hydrogen, air, and carbonic acid respectively, alike kept dry by contact with a large surface of oil of vitriol. In these experiments the evaporation was found to take place most rapidly in hydrogen, and least rapidly in carbonic acid; and as a mean of seven tolerably concordant results, the ratio of the rate of evaporation in hydrogen to the rate of evaporation in air, under the particular conditions of the experiment, was found to be as 2·68 : 1.

The influence of the particular contiguous atmosphere on the rate of evaporation of any particular liquid may be, and probably is, of a very complex nature. There are, however, two easily intelligible ways in which the particular atmosphere may act by virtue of its specific gravity. Thus a lighter or heavier gas or vapour ascends or descends bodily through another at a rate proportionate to the difference in their specific gravities, a very slight difference sufficing to bring about an upward or downward current of considerable activity. This upward or downward movement is well shown by introducing first heavy ether-vapour, and then light coal-gas, through a lateral opening made at about the middle of the length of a tall, somewhat wide, perpendicular glass tube, open at both ends; when it will be found that the ether-vapour, descending by reason of its heaviness, can only be inflamed at the bottom of the tube, while the coal-gas, ascending by reason of its lightness, can only be inflamed at the top. Now, the specific gravities of hydrogen, aqueous vapour, and air at the same temperature, being to one another as the numbers 1, 9, and 14·5 respectively, it is obvious that, whereas hydrogen saturated with water-vapour is heavier than dry hydrogen, air saturated with water-vapour is lighter than dry air. Accordingly, with a surface of water exposed to an atmosphere of originally dry hydrogen, the hydrogen in actual contact with the water will not, by becoming moist, acquire a tendency to rise up through the dry hydrogen, and so be removed from the surface of the liquid; whereas, with a surface of water exposed to an atmosphere of originally dry air, the air in actual contact with the water will, by becoming moist, acquire a tendency to rise up through the dry air, and so become removed from the surface of the liquid. And, having regard to this influence alone, water when occupying an inferior position should evaporate more rapidly into air than into hydrogen. It must be borne in mind that any given volume of moist air or gas is the sum of the volume of its constituent water-vapour, and of the volume of its constituent dry air or gas; and that the tension of the moist air or gas is the sum of the tension of its constituent water-vapour, and of the tension of its constituent dry air or gas, actually or virtually expanded by the addition to it of a certain volume of water-vapour. So that, with water boiling in a deep open vessel there may exist in close proximity to each other, almost pure water-vapour, different mixtures of water-vapour and air, and comparatively dry air, all having alike a tension of 760 millimetres of mercury.

But independently of their bodily movements in the form of currents, gases and vapours distribute themselves among one another by a proper molecular movement of diffusion—the relative diffusive mobilities of different gases or vapours being inversely as the square roots of their several specific gravities. Accordingly, with equal surfaces of water, exposed respectively to an atmosphere of hydrogen and to an atmosphere of air, the vapour produced from the surface of the water is interpenetrated and distributed through the contiguous space with greater rapidity by the highly-diffusive hydrogen than by the feebly-diffusive air, in proportion to their relative diffusion-velocities 3·8 and 1·0 respectively. And it is, doubtless, to the more rapid diffusion of hydrogen than of air into the vapour as formed, and the consequent more rapid supply to the liquid of an unsaturated atmosphere into which it can evaporate, that the more rapid evaporation of water, ether, and wood-spirit into an atmosphere of hydrogen than into an atmosphere of air, as in the experiments, for instance, already shown and described, is substantially due.

METHOD OF DETECTING THE MINERAL ACIDS IN VINEGAR.*

BY M. STROHL.

The author's method is founded upon the insolubility of oxalate of lime in dilute acetic acid and vinegar, and the solubility of the same salt in dilute mineral acids. The reagent, therefore, which he proposes for the detection of mineral acids in vinegar is oxalate of lime. But as reagents are generally more sensitive in proportion as they are freshly prepared, and approach nearer to the nascent state, the author prefers to produce oxalate of lime at the moment of the reaction by pouring into the liquid to be tested determined quantities of oxalate of ammonia and chloride of calcium in solution. As, moreover, so much more acid is required as there is oxalate of lime to dissolve, and consequently the degree of delicacy of the test diminishes with the quantity of the reagent added, in order to avoid excess of one or other of the two salts, the two solutions should be prepared to fulfil the following conditions: (1) To neutralize exactly in equal volumes; (2) to be sufficiently dilute to produce a turbidity—but a very perceptible turbidity—in vinegar free from mineral acids.

Preparation of the Reagent.—By a series of experiments it has been ascertained that one-fifth of an equivalent of each lime salt dissolved in a sufficient quantity of water to produce a litre, yields solutions fulfilling the required conditions; that is to say, if half a cubic centimetre of such solution of oxalate of ammonia and half a cubic centimetre of such solution of chloride of calcium be added to 50 cubic centimetres of vinegar, free from mineral acids, after agitation, a very apparent turbidity is produced.

Preparation of the Titrated Solutions.—The reagent once prepared under the best conditions for delicacy and clearness, it was then necessary to prepare acid liquors of known strength, from the mineral acids ordinarily employed in the sophistication of vinegar. The author used solutions containing two centigrams of anhydrous acid in each cubic centimetre. These he prepared as follows. He first determined the density of the different acids which he intended to use in his experiments, and then ascertained, from the tables drawn up by Bineau, Otto, and Ure, the percentage of anhydrous acid with which this corresponded. Supposing that the sulphuric acid had a density equal to 1·841: the tables showed that 100 grams would contain 80 grams of anhydrous acid (SO_3). As it was desired to obtain a solution one cubic centimetre of which should contain two centigrams of anhydrous acid, or what came to the same thing, of which 100 cubic centimetres should contain two grams of SO_3, by a simple calculation it was ascertained that that proportion of anhydrous acid would be contained in 2·5 grains of the acid in which the density had been taken. That quantity of acid of 1 841 density was therefore mixed with sufficient distilled water to make 100 cubic centimetres. The other acid mixtures were prepared in an exactly similar way.

Determination of the Limit of Sensibility of the different Acids.—50 cubic centimetres of vinegar were introduced into a test tube, then half a cubic centimetre of each of the solutions added, forming by their combination oxalate of lime; a very apparent turbidity was thus produced after agitation. Afterwards the titrated acid liquor was added by means of a burette, divided into tenths of a cubic centimetre, until the complete disappearance of the turbidity, *i.e.*, until the vinegar resumed the limpidity

* *Journal de Pharmacie et de Chimie*, vol. xx., p. 172.

which it had before the addition of the reagent. A certain volume of the acid liquor was thus employed. Suppose that six cubic centimetres had been required. The experiment was then repeated, only, instead of adding the acid after the oxalate of lime, it was added before and in smaller quantity. Thus, in this case, four cubic centimetres would be added to 46 cubic centimetres of vinegar, well mixed, the reagent added, and again shaken. If the turbidity disappeared immediately, four cubic centimetres was too much, and the experiment was repeated with a smaller quantity. If, on the contrary, the turbidity did not disappear by the addition of four cubic centimetres, a larger quantity was used in a fresh experiment.

Thus operating, the author ascertained the last limit of sensibility for each of the acids. Thus, for nitric acid he at first used 6·5 c.c., but operating as above the limit was lowered to 5·0 c.c. In this manner the limits for other acids were found to be:—

Hydrochloric Acid	2·5 c.c.
Nitric Acid	5·0 c.c.
Sulphuric Acid	3·5 c.c.

In each of these acid mixtures one cubic centimetre corresponded to two centigrams of anhydrous acid. Therefore, five centigrams of anhydrous hydrochloric acid, ten centigrams of anhydrous nitric acid, or seven centigrams of anhydrous sulphuric acid, present in fifty cubic centimetres of vinegar, is sufficient to prevent its being rendered turbid on the addition of the oxalate of lime. In other words, five centigrams of hydrochloric acid, ten centigrams of nitric acid, or seven centigrams of sulphuric acid (anhydrous) may be recognized in fifty cubic centimetres of vinegar; or, multiplying these terms by twenty, that is to say, taking a litre of vinegar, the presence of one gram of hydrochloric acid, two grams of nitric acid, or 1·4 grams of sulphuric in the litre can be detected.

Finally, as it may be interesting to know the limit of sensibility of the acids of commerce, the following calculations have been made according to the tables before referred to:—

			Grams.
Commercial Hydrochloric Acid	(sp. gr. 1·174)	.	2·85.
„ Nitric „	(sp. gr. 1·330)	.	4·40.
„ Sulphuric „	(sp. gr. 1·843)	.	1·71.

Résumé.—From the foregoing it may, therefore, be said that, in order to detect a mineral acid in a vinegar, it is sufficient to take fifty cubic centimetres of the vinegar, and add with a pipette half a cubic centimetre of each of the solutions of oxalate of ammonia and chloride of calcium, containing one-fifth of an equivalent of the salt per litre. If, after agitation, the turbidity does not completely disappear, the vinegar contains per litre less than 2·85 grams of hydrochloric acid, 4·40 grams of nitric acid, or 1·70 grams of sulphuric acid. If the turbidity disappears completely, the vinegar contains at least a quantity of acid represented by these figures.

IS THE EUCALYPTUS A FEVER-DESTROYING TREE?

BY MR. BOSISTO.

At a recent meeting of the Royal Society of Melbourne, a paper was read by Mr. Bosisto, in which he discussed the question whether the Eucalyptus is really a fever-destroying tree. As it is not long since that a Secretary of State, in reply to a question, expressed an opinion that the anti-malarial reputation of the Eucalyptus is founded on exaggerated statements, the evidence given in its favour by one so well acquainted with the trees of this genus as Mr. Bosisto will be read with interest. We therefore reproduce the following abstract of the paper from the *Melbourne Argus*:—

Mr. Bosisto said that in many places on the European continent, and elsewhere where experiments had been made to acclimatize the eucalypti, more especially the blue-gum species, the rapidity of its growth, its early maturity to a forest tree, together with the power to absorb considerable moisture, and to permeate the air with its peculiar odour, led to the belief that the tree, attractive in itself, exerted a beneficial influence upon malarious districts. In the consideration of the question whether the eucalypti tended to destroy miasmatic poison or to lessen malaria, it was necessary to take into account the whole of the eucalypti vegetation. Four-fifths of Australian vegetation consisted of the eucalyptus. Australia on the whole might be said to be pretty free from violent endemic or miasmatic poisons, and concerning the latter they might be said to exist only as the eucalyptus receded. The physical geography of Australia did not differ in general outline from that of other countries, but the vegetation of the eucalypti was absolutely indigenous to Australia and Tasmania. Baron Von Mueller described 130 species of this genus as existing in Australia. The physical properties of all eucalypts were that they cast their bark and that their leaves were evergreen, with, in some species, translucent cells. The chemical contents of a eucalyptus tree were neither poisonous nor virulent, and from the tree might be obtained a tannate gum resin, a volatile acid, and a volatile oil, peculiarly of eucalyptic origin. The two first were found in most parts of the tree, but the latter only in the leaves. In those three constituents the key to the question was to be found. The first matter to consider was whether there was any proof that these volatile bodies were set free in the air by the forces of the plant in unison with atmospheric agencies, and if so, when did the process take place, what was the quantity, and what was the probable sanitary effect. He then proceeded to give a detailed account of his experiments in the extraction of eucalyptus oil. The representative species were the manna gum, the odorata, the red gum, stringy bark, iron bark, blue gum, mallee, and peppermint. The mallee supplied an abundance of oil during the moist season, and the coast species during the summer months. In fact, as mid-winter approached, the coast species were ebbing in volatile products, and the others were flowing. The evidence of oil evaporation might thus be stated—that the desert scrub gums, after a winter of average rainfall, supplied the air with a continuous and even quantity of aromatic vapour, and kept up a vigorous vitality throughout the summer, and that a short season of rain, and a long dry summer, diminished the formation of oil and so lessened the exhalation; but, on the other hand, the species tending seaward increased their quantity after a short winter. The aroma of the volatile acid present in the eucalyptus might be detected in the air, along with that of the oil, when travelling in the bush. The extent of the eucalyptus vegetation in Victoria was given by Mr. Skene in his report to the Commissioners of the Exhibition as follows:—"The area of the whole colony was 55,644,000 acres, of which 5,560,000 acres was of dense mallee scrub; 6,225,000 acres of mountainous ranges, densely wooded with gums; and 38,922,000 acres of open timbered country." He calculated that mallee scrub would retain in the leaves, at one time, 4,843,872,000 gallons of oil, and the seaward species 280,891,000 gallons. The extent of mallee country in New South Wales and South Australia was estimated at 20 times the area in Victoria, and that would, calculated on the same basis, return 96,877,440,000 gallons of oil, held at one and the same time in a belt of country massed together over which the hot winds traversed. Considering, also, that the same condition existed throughout the greater part of Australia with the other eucalypts, he could not arrive at any other conclusion than that the whole atmosphere of Australia was more or less affected by the perpetual exhalation of these volatile bodies. From all that he could gather on the subject, he arrived at the conclusion that there was an active agency existing in Australian vegetation over that of other countries, and the exhalation from which gave to the atmosphere an invigorating and healthy tone. After examining all the evidence, Mr. Bosisto came to the conclusion that the eucalyptus is a fever-destroying tree.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 3, 1874.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CLAIMS OF THE MAJOR EXAMINATION.

An invincible argument for the adoption of a high standard of education might well be founded on the recollection of the past history of the Pharmaceutical Society, and the memory of those who once laboured in our ranks. Of the men who by indomitable perseverance have risen to eminence outside the pale of pharmacy, there must just now be no mention here. Rather we speak, as occasionally it is our bounden duty, of those who have never failed to be industrious workers in our own trade; and who, notwithstanding a marked scientific bent, have never cast aside the character of a simple chemist and druggist. From this race sprang the Pharmaceutical Society, and neither its origin nor its continuance can receive other explanation than that some years back a body of trading pharmacists were not content with the position of their craft in England. They compared it with that of other countries, specially with France; they measured themselves with those who were engaged in industrial pursuits of a more liberal nature, and the comparison was to their disadvantage. Lastly, there rose in their breasts a feeling of profound dissatisfaction that, linked so closely as their calling was with the beneficent art of the physician, they were but poorly qualified to share his professional instincts or to become his intelligent adviser. A new train of thought led to energetic action, the consequences of which remain until this day; but in whatever light we view either the action or the thought, we can assign to it no other motive than that inspired by honour, or the craving for improvement. Proudly we refer to the last proceedings of the Linnean Society, where we find enrolled the memorials of Henry Deane and Thomas Morson. We appeal to the career of men like these, and ask if we of a later generation should not strive to acquire something better than a legal qualification for the exercise of our trade?

It is not well to linger too long over the cypress, or to dwell too exclusively in the memories of the past: let us turn from the dead to the living—rather from the dead who are yet speaking, to the living whose works are an epistle known and read of all men.

One fact admits of no denial; pharmacy in England can boast of a very respectable series of Fellows of various learned bodies, who have gone far beyond the immediate requirements necessary for *keeping open shop*, or compounding physic. Some few of these, by an accident of date, were exempt from even the form of an examination; the rest have shown a rare willingness of disposition to develop the spirit of the Association to which they belong. Law has made compulsory a certain portion of these generous impulses, and has rendered them matters of obligation.

Seeing, then, how much was accomplished by spontaneous effort, and the importance of the results obtained, the Government was not slow to perpetuate and ratify the new conditions under which pharmacy was placed; and when it passed an imperative enactment compelling a standard of qualification, it found, ready to hand, an existing body prepared—nay, entitled—to carry out its intentions.

But the events of the past thirty years made such a provision of itself inadequate. The Minor Examination is a safeguard standing midway between the public and the pharmacist, and on both sides is a righteous measure of precaution. In its creation a paternal Government has released itself from responsibility, but it would have feebly interpreted the spirit of the age had it not provided that to pharmacy also, as a branch of learning, a road to honourable distinction should be accessible. Once more, then, we make a direct appeal in favour of the Major Examination. We are convinced that a mass of our younger readers know little the reason of its institution. That so few venture to claim its privilege cannot be due to a sudden degeneracy of feeling, but to a misconception of its design, and an ignorance of the traditions by which it is surrounded. The theory seems to be, What is the lowest modicum of knowledge with which I can slip through life? What is the minimum of intellectual strain with which I can exercise an intellectual calling? So the pharmacist, whom no one forced to enter upon a trade-science, stands aloof from those whose thirst for mental culture is directed mainly by inclination. The artisan goes home, and in his after-hours repairs to South Kensington, where he learns to draw or model; the London workmen crowd to hear art-lectures; and the Strand shopmen frequent the admirable evening classes at King's College. But he, compelled by stress of circumstances to have a streak of science in his composition, thinks *that* an evil sufficient for its day. Another examination, and not compulsory! *Miserere!* Alps on Alps! And the half-open gates of knowledge creak back upon their hinges.

The subject has always appeared to us in as practical a manner as the Board of Examiners could desire. Hard it is to grapple with the minutiæ of botanical research; to learn about roots and stems, about cells and tissues, and Professor Bentley best knows what. Then succeeds the keen delight which Nature never yet refused to the diligent student of her mysteries. Hard it is to stumble over the rough stones of materia medica; but there are men amongst us who find their chief happiness in its pursuit. Hard it is, and difficult beyond measure, to master the preliminary details on which chemistry is built; but, patience! there will come a time when the sense of power will alone be a sufficient compensation. And though it may be very nice to see that the acquirement of this higher standard is only an equation on the right side of which is money—that from our ranks the public analyst will be selected—that to us chemists and druggists the farmer will intrust his phosphates, the dyer submit his chlorides, and the manufacturer the salts which concern his industry—we back our appeal in favour of the Major Examination on the personal satisfaction which passing it will bestow. We cannot bear to think that those who must earn a livelihood behind a druggist's counter should go through so large an amount of preparation, and not let their studies issue in their full legitimate results. We want our members to take up their right position—to become the friend of the physician, his aid and fit companion—to be abreast of the intellectual culture of the world—to be accepted in the social circle on equal and honourable terms, and to let their sons feel some ambition to follow in their steps. Quite as much we wish them to be prosperous in their affairs—to have a bright pharmacy, a good family connexion, and customers without stint. The New Regulations will not be found futile if accepted in their entirety; for there is no surer guarantee for ultimate success than that our pharmacists should be thoroughly well-grounded and practical business men.

THE COMMENCEMENT OF A NEW SESSION IN BLOOMSBURY SQUARE.

It will be seen from the official notices that the sessional work of the Pharmaceutical Society commences on Wednesday next, the 7th of October, when the first of the evening meetings will be held, at which, after the distribution of the sessional prizes and certificates to the students who successfully competed for them in the last session of the Society's school, Mr. R. W. Giles, of Clifton, will deliver an address to the students, and especially to those who are now entering the school. The Lectures and Laboratory instruction will, in fact, have commenced before the evening meeting takes place. The practical class under Professor Attfield will have met on Thursday, the 1st of October; Professor Bentley's class on Friday, the 2nd, and Professor Redwood's will meet on Monday, the 5th of October. The examinations, of which official notice is elsewhere given, will soon follow, and the Society's House in Bloomsbury Square, after the thorough cleaning and decoration it has received during the recess, will in a few days resume its accustomed activity.

OPIUM IN AMERICAN PROPRIETARY PREPARATIONS.

In a recent number of the *American Chemist*, Mr. S. Dana Hayes, State Assayer for Massachusetts, refers to the increasing use in the United States of opium and morphia in cough mixtures, tooth-washes, lotions, liniments, and other proprietary medicines. He states that some analyses made recently showed that the quantity of morphia present in several medicines intended for internal use varied from $\frac{1}{4}$ of a grain to $1\frac{1}{2}$ grains in the doses ordered in the printed directions accompanying them. One nostrum, a "sure cure for the opium habit," was found to be a clear solution of sulphate of morphia coloured pink by aniline red and sweetened with sugar. Of this a dose containing nearly two grains of sulphate of morphia was directed to be taken three times a day, by a patient suffering severely from depression. A "brandy," sold by a dealer in "medicines" in the country, contained morphia equal to $2\frac{1}{2}$ grains of opium in four fluid ounces; a tooth-wash contained nearly $\frac{4}{10}$ of a grain of morphia in each fluid ounce; and a cough mixture contained more than $\frac{3}{10}$ of a grain in the dose ordered for a child.

IMITATION OF TRADE-MARKS.

That "all is fair in love and war" is a saying that has long had considerable currency. But this "easy virtue" has not yet been extended to competition in trade, unless, indeed, such competition be only a form of war. In fact, it has been thought necessary in many countries that a law should be enacted, having for its special object the prevention of one form of unfair competition,—the imitation of trade-marks. Two complaints of breach of such a law, by the imitation of labels, etc., used for popular proprietary medicines, have recently been heard in France, and in another part of this Journal will be found the report of a prosecution in this country for an alleged similar offence.

In Paris, the success with which M. Lebeault, a pharmacien, has for some years carried on the manufacture and sale of an article under the name of "Vin de Bugeaud," appears to have roused the cupidity of two other persons named Caut and Subert, who associated themselves with a pharmacien named Bourgeaud to bring out a similar article under the name of "Vin de Bourgeaud." More than this, they appear to have sought to add to the confusion caused by the similarity of names by the adoption of similar bottles, labels, and wrappers. M. Lebeault appealed to the tribunals, and, as the result of the trial and two appeals, obtained a decision that his opponents should always insert Bourgeaud's Christian name before the surname, wherever it occurred, on bottle, label, or handbill; also, that they should pay him 3000 francs as damages.

The second French case was very similar. The complainant was a Dr. Felix Dehaut, who has introduced an article under the name of "Pilules purgatives Dehaut." A M. Denaut, in conjunction with a M. Hugo, pharmacien, brought out "Pilules purgatives Denaut," imitating the labels, etc., of M. Dehaut very closely. This the Court decided to be a fraudulent imitation of the trade-mark which would be likely to deceive the public, and it ordered the confiscation of the stock seized and the payment of 2000 francs as damages.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

September 22nd, 23rd, 24th, 25th, and 28th, 1874.

Present—Messrs. Ainslie, Buchanan, Gilmour, Kinninmont, Noble, Tait, and Young.

MINOR EXAMINATION.

Seventy-five candidates presented themselves for this examination. *Forty-seven* failed. The following *twenty-eight* passed, and were declared qualified to be registered as Chemists and Druggists :—

	Name	Town
	*Couper, Charles James	Edinburgh.
	*Webb, Frederick Brooks	Birmingham.
	Wylie, David Neil	Edinburgh.
	Hindes, James	Edinburgh.
	Presslie, Robert Dowell	Aberdeen.
Equal.	Dawson, George Alan	Hanley.
Equal.	Roebuck, Alfred	Manchester.
	Gardner, Robert	Kelso.
	Forgie, William	Falkirk.
Equal.	Gilbert, William	London.
Equal.	Nottingham, Thomas	Streatham.
	Plant, Frank George Lawrence	Ashton-under-Lyne.
	Hamilton, Robert	York Town.
	Forrest, John Kerr	Edinburgh.
	Moore, Joshua	Preston.
Equal.	Challinor, Samuel McMillan	Bolton.
Equal.	Horton, James Alfred	Aberdeen.
Equal.	Alldridge, William Edward	Birmingham.
Equal.	Fenton, Thomas	Edinburgh.
Equal.	Louden, William T.	Dumfermline.
Equal.	Robinson, Edward	Birmingham.
	Storie, Robert	Edinburgh.
Equal.	Haworth, Hezekiah	Blackburn.
Equal.	Watt, George Adam	Hartlepool.
	Heynes, William Henry	Woodstock.
	Broomhead, George Emmet	Aberdeen.
	Heald, Samuel Haldine	Wakefield.
	Fingland, James	Thornhill.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Four candidates presented themselves for this examination. *All* passed, and were declared qualified to be registered as Chemists and Druggists :—

Lateward, John Richard	Rugeley.
Macfarlane, James	Glasgow.
Roberts, Owen	Liverpool.
Sutherland, Daniel	Upper Clapton.

* Passed with Honours.

BENEVOLENT FUND.
